

Practice Analysis: The Foundation of the Test Plan

The NCLEX-RN test plan is based on the results of a practice analysis conducted every 3 years of the entry-level performance of newly licensed registered nurses and on expert judgment provided by members of the National Council's Examination Committee as well as a Job Analysis Panel of Experts. The job analysis asks newly graduated nurses to rank the nursing activities that they perform on a regular basis. The questions used on the test plan, therefore, include those activities that nurses commonly perform. For example, the 2014 RN practice analysis revealed that nursing practice commonly involved activities such as performing procedures necessary to safely admit, transfer, or discharge a client; providing and receiving reports on assigned clients; and assigning and supervising care provided by others (LPN/VN, unlicensed assistive personnel, other RNs) (National Council of State Boards of Nursing, Inc., 2015).

The NCSBN also used the findings from the practice analysis activity statements to generate knowledge statements, the knowledge needed by newly licensed nurses to provide safe care (National Council of State Boards of Nursing, Inc., 2015). The findings of this second report are used to inform item development for the NCLEX-RN examination.

2 NCLEX-RN® Test Questions and Strategies for Answering Them

Introduction

The test questions used on the NCLEX-RN exam are written to test the knowledge, skills, and abilities essential to provide safe client care. Understanding the types of questions, the cognitive level of the questions, as well as the thinking processes used to answer the questions is essential for test success. This chapter provides information about the test items used on the NCLEX-RN exam and offers strategies for answering questions for various types of test items and levels of the cognitive domain.

Types of Test Items

The NCLEX-RN examination uses eight types, or formats, of test items (National Council of State Boards of Nursing, Inc., 2015). These include multiple-choice items and seven alternate item formats: multiple-response, fill-in-the-blank (calculation), hot-spot, chart/exhibit, drag-and-drop/ordered-response, graphic options, and audio items. Questions can also be written using video clips as prompts for questions. Although these questions are not currently being used by the National Council of State Boards of Nursing (NCSBN), video questions are included on thePoint as an additional way for you to develop your critical thinking and test taking skills. To log into thePoint, go to <http://thepoint.lww.com>. (The code for accessing the site is printed on the inside front cover of the book along with specific instructions for accessing the questions.)

Although each type of item tests your understanding of nursing content and is developed using the same test development process, each type of test item requires you to respond in a different way. Because alternate item formats test knowledge, skills, and abilities in a variety of ways, there are increased opportunities for you to demonstrate your competence (Wendt & Kenny, 2009). All test item types are scored as either correct or incorrect; no partial credit is awarded for any question type (National Council of State Boards of

Nursing, Inc., 2015).

All eight types of test items and video inclusion test questions are used in this review book and on thePoint to give you the opportunity to learn how to answer each type of question. You can also find examples of these types of questions on the NCSBN Web site (www.ncsbn.org), in the candidate tutorial that precedes each licensing exam at the Pearson VUE Web site (www.pearsonvue.com/nclex), and in the candidates' bulletin that you will receive prior to taking the licensing exam.

Multiple-Choice Item

Multiple-choice items include a scenario/situation, a question, and four answers—only *one* of which is correct (see [Fig. 2.1](#)). The scenario provides information about the client or care management situation. The question (stem) poses the problem to solve. The question may be written as a direct question, such as “What should the nurse do **first**?” or as an incomplete sentence, such as “The nurse should:.” The answers (options) are possible responses to the stem. Each stem has one correct option and three incorrect options. The options may be written as complete sentences or may complete the sentence stem stated in the question. Multiple-choice items are the most common type of test item used on the licensing exam.

FIGURE 2.1
Sample Multiple-Choice Item

A 7-year-old client with type 1 diabetes is sick with the flu. What is the most important information for the nurse to convey regarding diabetes management during illness?

- ☐ 1. Blood glucose needs to be checked more frequently during illness.
- ☐ 2. Children require less insulin when they are sick with the flu.
- ☐ 3. Urine ketones should be checked every other day during illness.
- ☐ 4. Increase intake of fluids high in carbohydrate to prevent diarrhea.

Strategies for Answering Multiple-Choice Questions

- Read the scenario, and relate the question and answers to the data provided in the scenario. Pay particular attention to information, if included, about the client’s age, family status, health status, ethnicity, place of care, or point in the care plan (e.g., early admission vs. preparation for discharge).
- Answer the question before looking at the possible answers.
- Choose the answer that best matches the answer you first thought was correct.
- Recognize that only ONE answer is correct.

- Double-check your answer to be sure you have responded to the question; note particularly key words such as **first, except, not, most, last**; be sure that you are basing your answer on best nursing practice, not experience with one client or in a particular clinical agency.

Multiple-Response Item

Multiple-response items are similar to multiple-choice items, except that they include four to six answers and have two or more correct answers, and the others will be incorrect; there will not be an instance in which the answers are either all correct or all incorrect (see [Fig. 2.2](#)). These questions will ask you to identify all of the answers that are correct (“Select all that apply.”). Multiple-response questions will be scored as being either correct or incorrect; no partial credit is given for selecting some of the correct responses.

FIGURE 2.2

Sample Multiple-Response Item

The client states to the nurse, “I take citalopram 40 mg every day as my healthcare provider (HCP) prescribed. I have also been taking St. John’s wort 750 mg daily for the past 2 weeks.” Which findings would indicate that the client is developing serotonin syndrome? Select all that apply.

- ☐ 1. confusion
- ☐ 2. restlessness
- ☐ 3. constipation
- ☐ 4. diaphoresis
- ☐ 5. ataxia

When using the text pages in this book to answer the multiple-response questions, you can make check marks in the boxes located in front of the answers. When taking the actual NCLEX-RN exam, you will place your cursor on the box in front of the answer you wish to select and click on the box; a check mark will appear indicating that you wish to select that answer. To change an answer, you can use the mouse to remove the check mark from that box.

Strategies for Answering Multiple-Response Questions

- Read the question carefully, and determine what it is you are to select, for example, all possible side effects of a particular drug, all intended outcomes of a particular nursing intervention, all of the elements of a teaching plan for a client with a particular health problem, or all instructions a nurse should give to a client who is being discharged.
- Read each answer, and determine if it is true or false as it pertains to the question.
- Consider how the answers are “clustered” and how the correct answers are related.
- Be sure you have selected ALL of the possible correct answers.
- Double-check your answer by reviewing the answers you did NOT check, and be sure they are incorrect and should not be included in the answer.

Hot-Spot Item

Hot-spot items involve identifying the location of a specific item, such as an appropriate injection site, assessment area, or correct part of a waveform. The question will be phrased, “Identify the location...” or “Select the area...” (see [Fig. 2.3](#)).

FIGURE 2.3 Sample Hot-Spot Item

The nurse is preparing the client diagnosed with pleural effusion for a left-sided thoracentesis. The x-ray shows fluid in the pleural cavity. During the preparation for the procedure, the client asks where the healthcare provider (HCP) will “put the needle.” Select the appropriate site from the diagram below.

When answering hot-spot questions in the book, you should place an X on the illustration provided to identify the proper area and then refer to the answer section for that chapter to confirm your response. On the actual NCLEX-RN and for the questions on thePoint, you will use the mouse to move your cursor over the area you want to select and then left-click the area. A red “X” will appear over the area you have selected. If you make an error, you can move the cursor to the part of the figure that is the answer you wish to enter.

Strategies for Answering Hot-Spot Questions

- Read the question carefully, and answer the question first by visualizing an answer; then look at the figure to mark your answer.

- Double-check your answer to make sure you have selected the correct “spot” based on evidence for best nursing practice.

Fill-in-the-Blank (Calculation) Item

Fill-in-the-blank items involve calculations, such as determining a drug dose, calculating an IV drip rate, or totaling intake-output records (see [Fig. 2.4](#)). These items can be answered with a number. On the NCLEX-RN exam, if you do not enter a number, you will receive an error message that will prompt you to “enter a numeric answer.” When an answer includes a measurement amount such as milliliters (mL), grams (g), or inches (in), the measurement unit will be stated in the stem of the question and supplied in the answer box; thus, you will not include the unit of measure as part of your answer. The question will indicate if you are to round your answer and, if so, to how many decimal places.

FIGURE 2.4

Sample Fill-in-the-Blank Item

The healthcare provider (HCP) prescribes an intravenous infusion of 5% dextrose in 0.45 normal saline to be infused at 2 mL/kg/h in an infant who weighs 9 lb (4.1 kg). How many milliliters per hour of the solution should the nurse infuse? Round to one decimal place.

_____ mL/h.

When answering fill-in-the-blank questions on the text pages of this book, you can use paper and pencil, a handheld device with a calculator, or a calculator to determine your answers. However, on the actual NCLEX-RN exam, a drop-down calculator will be available for you to use to calculate your answers. The division sign used is similar to the one used on the Microsoft Calculator (/); be sure to familiarize yourself with the mathematical function keys. To practice calculations required for fill-in-the-blank questions, use the calculator on your computer.

Strategies for Answering Fill-in-the Blank Questions

- Determine what calculation the question is asking you to perform (e.g., add, subtract, or use a formula).

- Write the calculation on the erasable write board provided at the testing center.
- Access the drop-down calculator from the computer to perform the appropriate mathematical function.
- To avoid calculation errors, be sure that you do not enter numbers rapidly when you are using the calculator.
- Round the numbers, as directed, to one or two decimal points; round the number after completing the calculation. If rounded numbers are required to answer the question, the decimal point must be included in the answer.
- Place your answer on the appropriate line.
- Double-check your answer using a logic test—is this answer plausible? Did I perform the correct mathematical function? Is the answer appropriate for the unit of measure required in the question?

Chart/Exhibit Item

Chart/exhibit items present data from a chart, graph, or table. Data from a client's chart will be presented from one or more chart "tabs" such as prescriptions, history and physical, laboratory results, miscellaneous reports, imaging results, flow sheets, intake and output, medication administration record, progress notes, and vital signs (see [Fig. 2.5](#)). On the actual NCLEX-RN exam, you will be prompted to "click on the exhibit button below for additional client information." You will then use the data presented in the scenario and on the chart or exhibit to make a nursing decision. For example, you will click on up to three tabs to locate data, and then you will interpret the data, validate if the data are correct or sufficient, and then be asked to respond to a question based on the data.

In this book, chart/exhibit questions show data on 1 or 2 "tabs" and then ask you to use the data to respond to the question. When these types of questions are administered by the computer (as in the NCLEX-RN exam), you may be asked to determine which "tab" to use to locate the information that is required to answer the question. You will click on the tab to open the tab(s), and a "pop-up" window will appear on the computer screen.

FIGURE 2.5 Sample Chart/Exhibit Item

The nurse is reviewing the history and physical and healthcare provider (HCP) prescriptions on the chart of a newly admitted client.

History and physical tab

Subjective:	19-year-old reports a constant cough for the past "few weeks" with "dark" sputum for the past few days. Has night sweats, 10-lb (4.5-kg) weight loss in the past month, and "always" being tired. He took one Tylenol about an hour prior to arrival.
Objective:	
BP	120/64
HR	84/reg
Resp	26/unlabored/slight wheezing in right lower lobe posteriorly
O ² Sat	92%
Temp	99.9°F (37.7°C) oral
Skin	Warm, slightly diaphoretic
Nonproductive cough at this time	
Assessment:	Possible respiratory infection
Physician prescriptions tab	
	Chest x-ray
	Sputum specimen
	Oxygen at 2 L per nasal cannula

The nurse should first:

- ☐ 1. initiate airborne precautions.
- ☐ 2. apply oxygen at 2 L per nasal cannula.
- ☐ 3. collect a sputum sample.
- ☐ 4. reassess vital signs.

Strategies for Answering Chart/Exhibit Questions

- Read the scenario and question carefully to understand the context for the data to be provided in the chart or exhibit. For example, are you looking for vital signs? Would an elevated pulse or drop in blood pressure be consistent with the context of the question and provide data for making a nursing decision?
- Read the information provided on the chart or exhibit, and identify the information that is essential to answer the question.
- Review the chart or exhibit “pop-up box” as many times as needed.
- If necessary, take notes on the erasable note board provided at the testing center.
- Answer the question only from data provided in the chart or exhibit and from the data presented in the scenario.
- Double-check your answer by being sure you have obtained all of the data necessary to answer the question and that the answer is complete and plausible.

Drag-and-Drop/Ordered-Response Item

Drag-and-drop/ordered-response items require you to place information in a specified order (see [Fig. 2.6](#)). For example, the question might ask you to put steps of a procedure in order, or provide information about several clients, and ask you to determine the order of priority in which each client should receive nursing care. Or the question may ask you the order in which to teach a client about a procedure or self-care process. There may be up to six options to arrange in a specific order. The questions will be scored as correct or incorrect; there is no “partial credit” for having part of the answer in the correct order.

FIGURE 2.6

Sample Drag-and-Drop/Ordered-Response Item

The nurse’s assignment consists of four clients. Prioritize in order from **highest to lowest priority** in what order the nurse would assess these clients after receiving report.

1. An 85-year-old client with bacterial pneumonia, temperature of 102.2°F (42°C), and shortness of breath.
2. A 60-year-old client with chest tubes who is 2 days postoperative following a thoracotomy for lung cancer and is requesting something for pain.
3. A 35-year-old client with suspected tuberculosis who has a cough.
4. A 56-year-old client with emphysema who has a scheduled dose of a bronchodilator due to be administered, with no report of acute respiratory distress.

When answering drag-and-drop/ordered-response items in the text of this book, you will write the appropriate step number next to the answer choice. For example, write #1 next to the first step in the process, #2 for the second step in the process, and so on until all answer choices have been used. On the actual licensing exam, you will drag each response from the left-hand column and drop it into the correct order on the right-hand column. You can move the items around until you have them in the correct order and then click “submit” to enter your answer. If you need to change your answer, you can drag the response to another position and reorder the responses. The questions on thePoint function in much the same way, except that you will click on “Next” to proceed to the next question.

Strategies for Answering Drag-and-Drop/Ordered-Response Questions

- Read the key words in the stem of the question that indicate the order in which you are to place the answers.
- Test the logic of your answer.
- Be sure all items have been placed.
- Double-check your answer by reviewing the correct order for the answers and that you have placed your answers in the order in which you intend to answer the question. One answer out of order will cause the question to be counted as incorrect.

Graphic Option Item

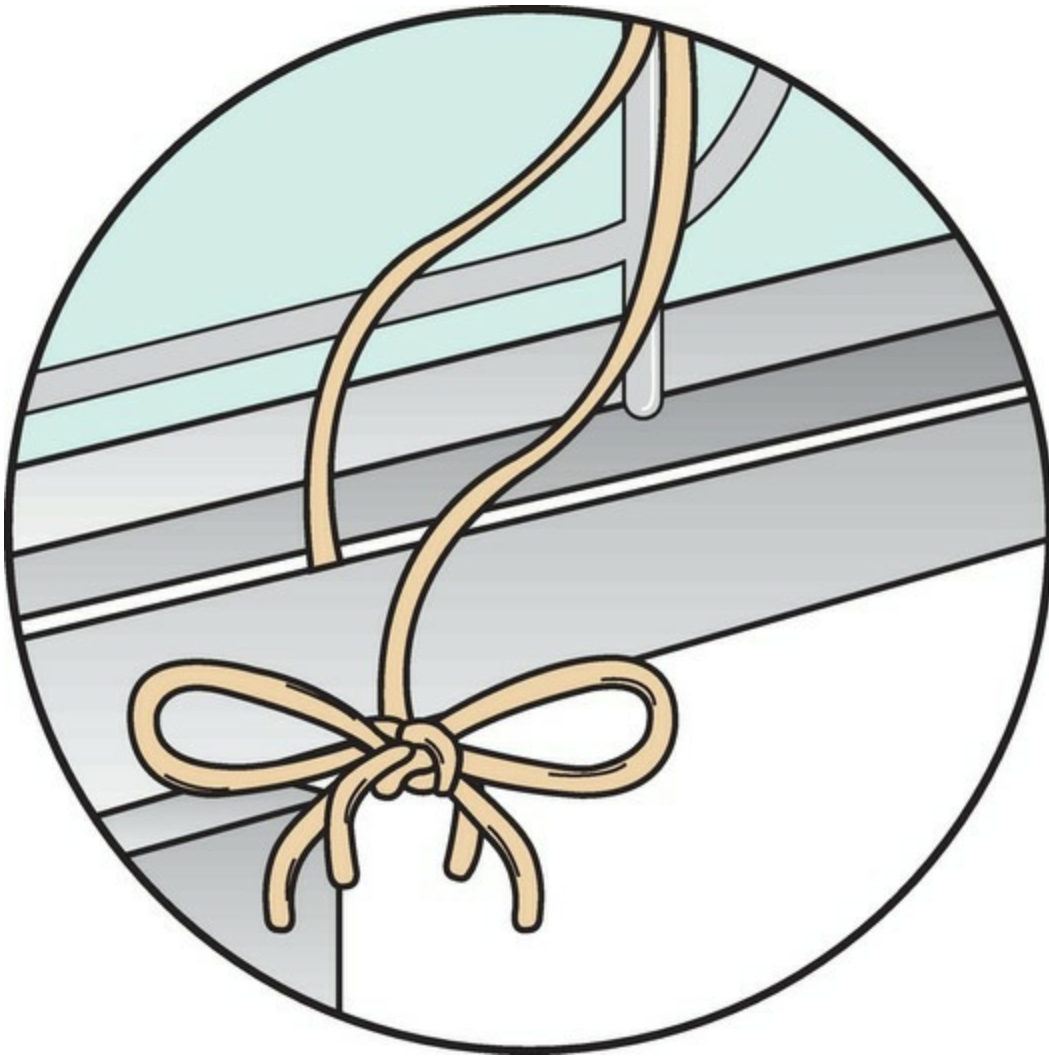

Although graphics can be used as a part of the *question* (see [Fig. 2.12](#)), with graphic option items the *answers* to these questions are presented as a graphic (see [Fig. 2.7](#)). Graphic option items use graphics (figures, illustrations, photos) in the answers to the questions. You will need to select the correct answer(s) from the graphic options offered as possible answer(s) to the - question.

In the text of this book, you can use your pencil to mark the correct answer to a graphic option question. On thePoint and on the actual NCLEX-RN exam, you will click on the circle in front of the graphic that represents your answer. To change your answer, click on another circle.

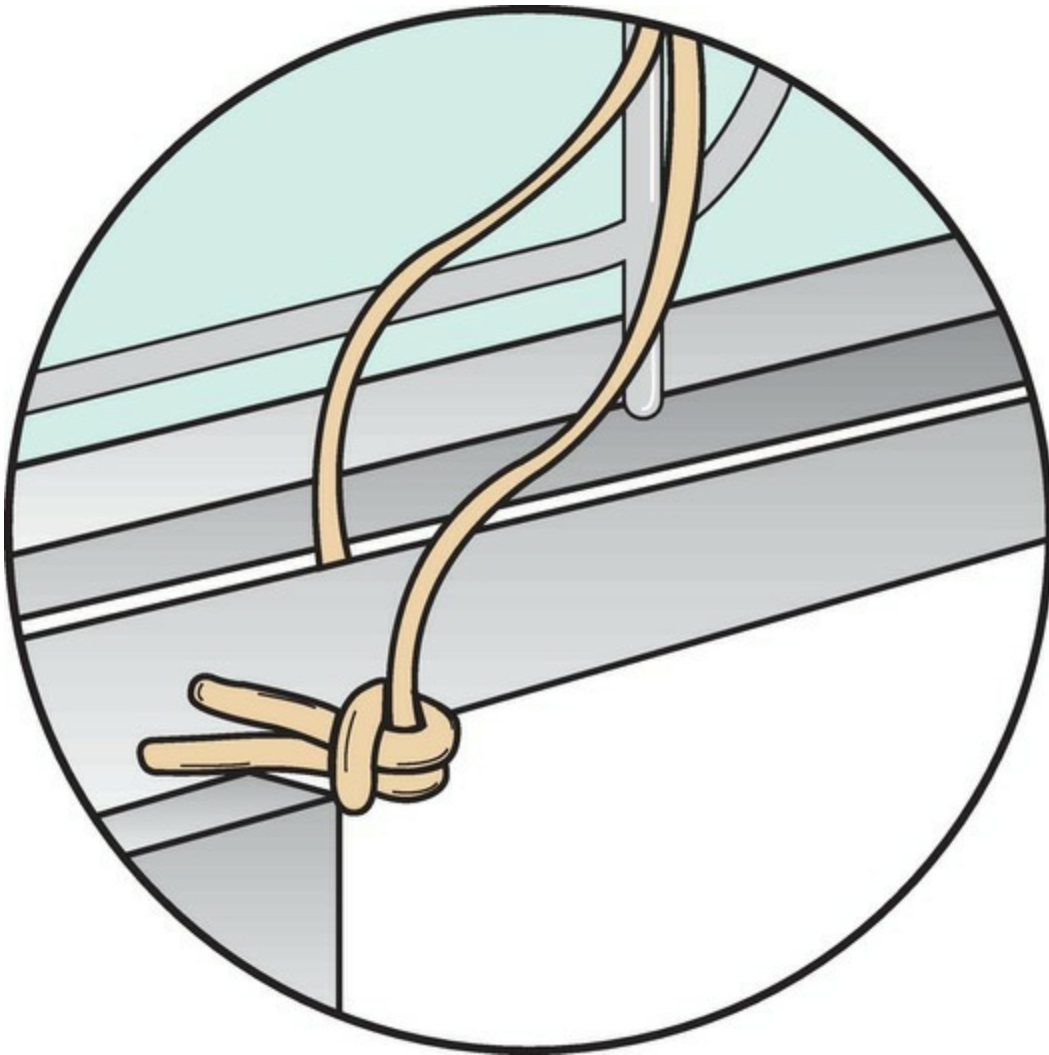

FIGURE 2.7 Sample Graphic Option Item

Which is the correct knot used to secure a restraint correctly to the bed frame?

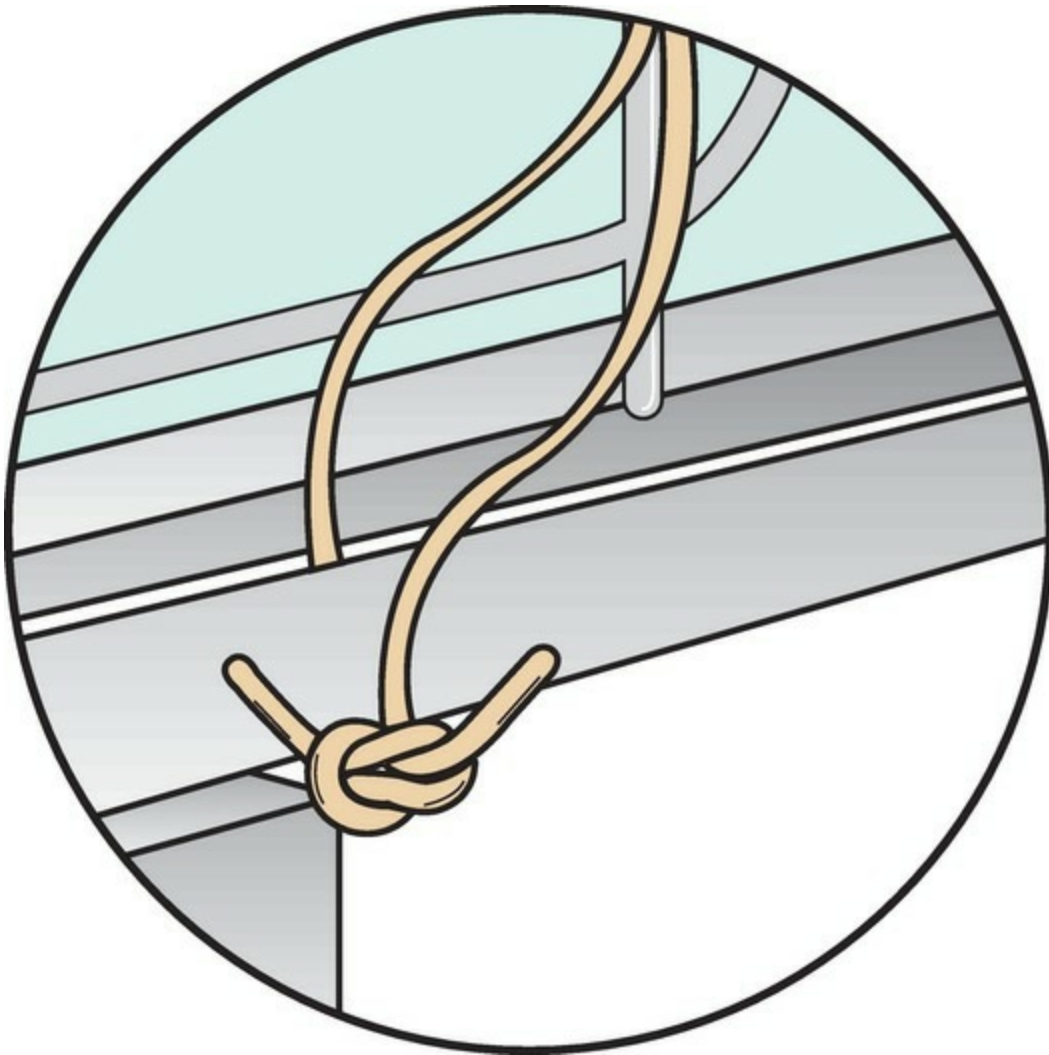

☐ 1.

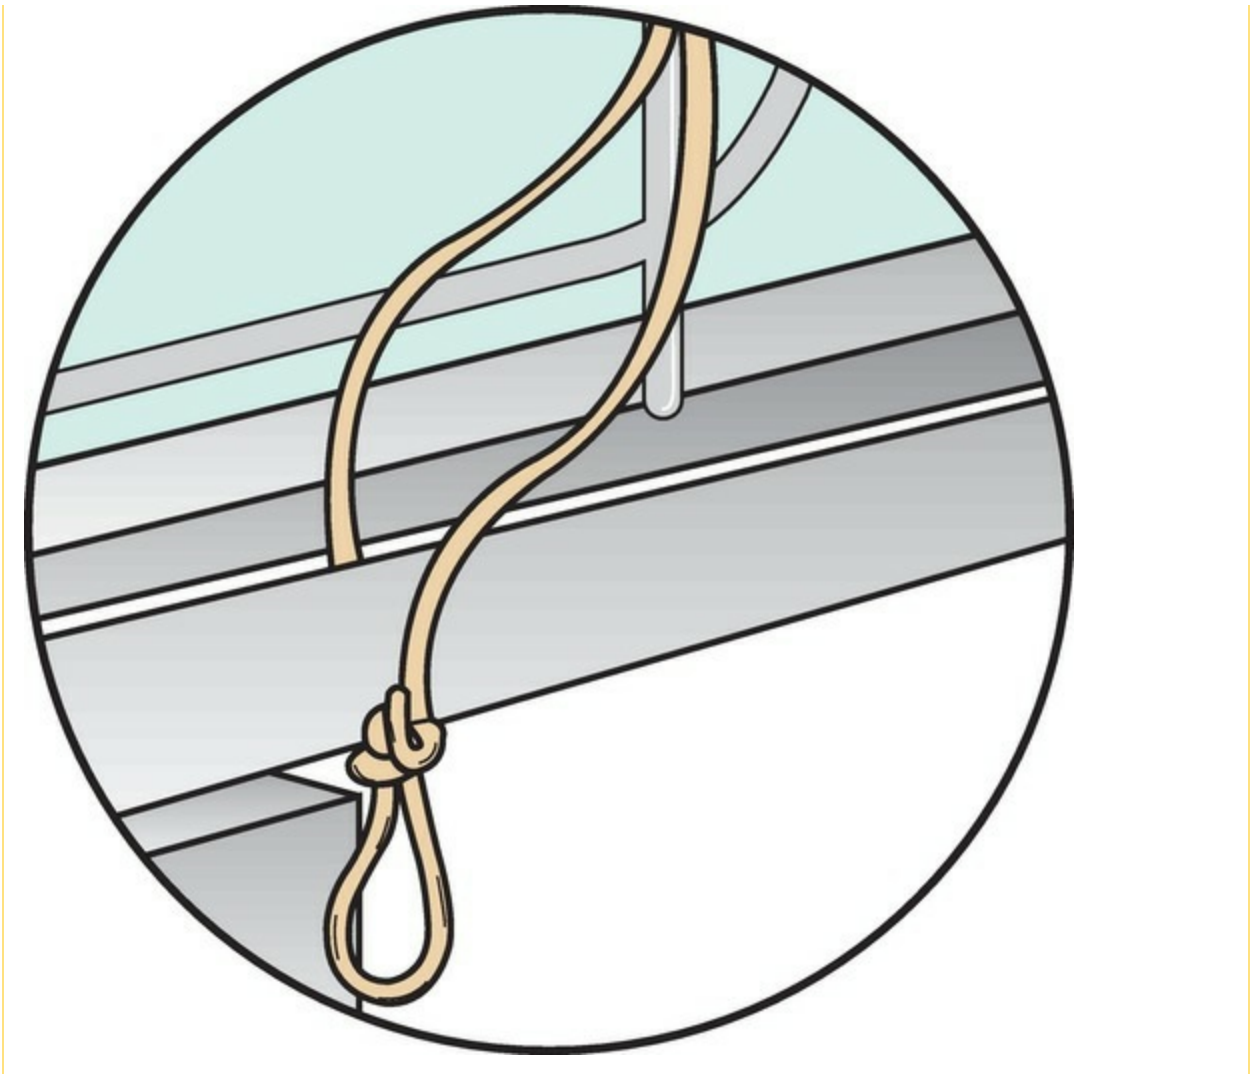

□ 2.

□ 3.

□ 4.

Strategies for Answering Graphic Option Questions

- Read the question carefully, and visualize the answer before looking at the options presented with the test item.
- Look carefully at each graphic option, and be certain you understand the differences among the options.
- Select the option that best answers the question.
- Double-check your answer by reviewing the question, answering the question based on best nursing practice, and matching the answer to the graphic option.

Audio Item

Audio items include a short audio clip with data that are essential to answer the question. (See [Fig. 2.8](#) for an example of how a question is *written*; go to thePoint to *hear* the actual audio clip or to practice answering other audio questions.) For example, you could be asked to listen to breath sounds, heart sounds, bowel sounds, or verbal interactions. The question will indicate that you should click on the play button to listen to the audio clip. You will be able to play the audio clip as many times as needed to answer the question. The question may ask you to identify the sound on the audio clip, for example, type of breath sound, or you may be asked to make a nursing judgment and/or select a nursing action based on your interpretation of the sound.

In this review book, the audio questions are presented on thePoint. You will be able to listen to the sounds and choose the correct answer. When taking audio test questions on the actual NCLEX-RN exam, you will have headsets to use, and you will be able to adjust the volume.

Strategies for Answering Audio Questions

- Read the test item carefully to understand the clinical context in which the scenario occurs.
- Listen to the audio clip before answering the question; listen to the audio clip as many times as needed to answer the question.
- Relate the sounds in the audio clip to the scenario in the test item; if the question asks you to make a nursing decision or select a nursing action, base your answer on your interpretation of the sound and best nursing practices.
- Double-check your answer by reviewing the question and answering the question based on best nursing practice.

FIGURE 2.8
Sample Audio Item

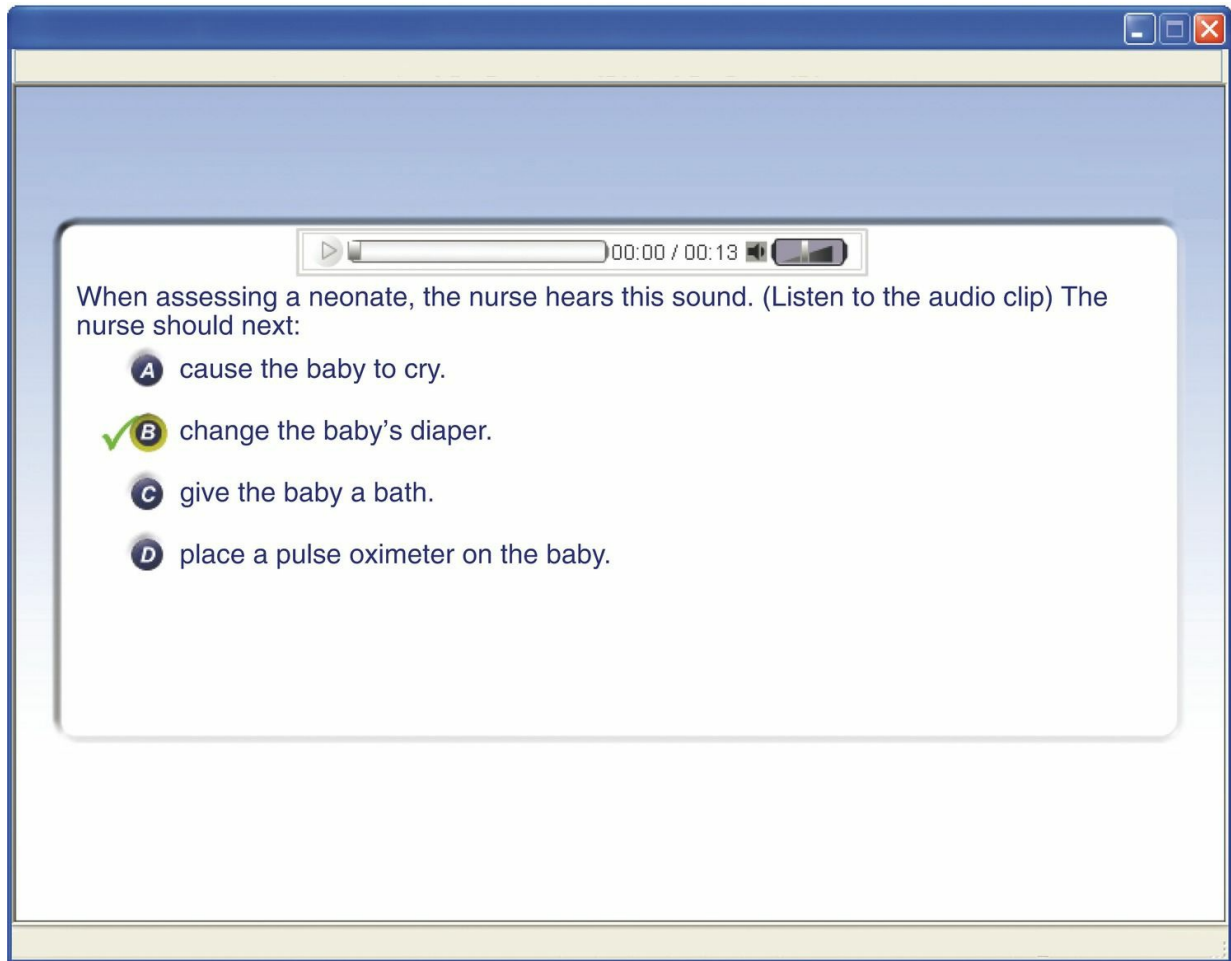

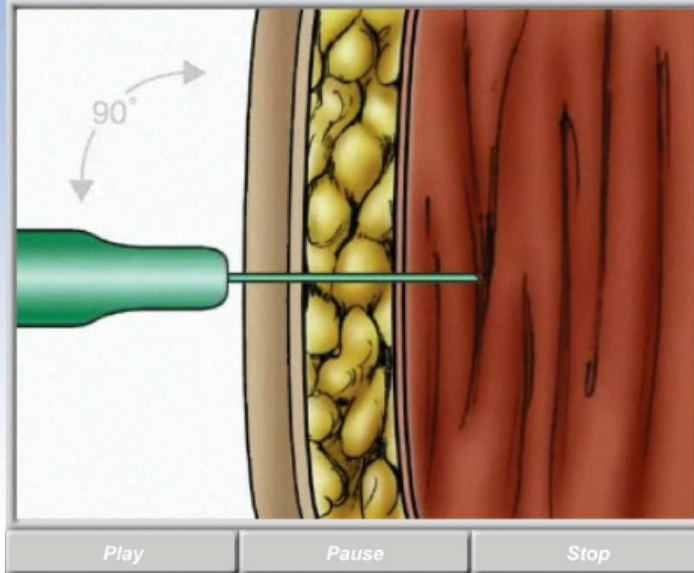

FIGURE 2.9
Sample Video Item

The nurse is administering 5,000 units heparin subcutaneously to a client (view the video). The nurse should:

- ☐ A Deposit the heparin deep in the muscle.
- ☒ B Use a shorter needle.
- ☐ C Inject the heparin at a 45 degree angle.
- ☐ D Rotate the tip of the needle.
- ☐ E Aspirate prior to injecting the heparin.

Video Item

Video items use video clips to present a clinical situation or to demonstrate a procedure. The question will be based on information you have viewed in the video clip. Although video items currently are not used on the licensing exam, we have included several examples on thePoint. Your faculty may use these questions in classroom testing situations, and you should be familiar with how these questions are designed and how to answer them. (Figure 2.9 shows how video questions are *written*; refer to thePoint for an *actual* example of a video item.)

Strategies for Answering Video Items

- Read the question carefully to understand the clinical context of the question.
- Anticipate what the video clip will show, what you should pay particular attention to when you are watching the clip, and how the question relates to what is being shown in the video clip.
- Play the video clip as often as you need to view the action; look for actions that are correct or not correct.
- Double-check your answer by comparing the video clip and the answer options and selecting the option that represents best nursing practices.

Cognitive Levels of Test Items

The cognitive level of questions refers to the type of mental activity such as critical thinking and clinical reasoning required to answer the question. The cognitive levels used to write test items for the NCLEX-RN are derived from the original Bloom's taxonomy and the Bloom's revised taxonomy of the cognitive domain (Anderson & Krathwohl, 2001; Su, Osiek, & Starnes, 2005) (see Table 2.1). The lowest level of the taxonomy is the *knowledge* (or *remember*) level and involves the ability to remember or recall facts. The next level of the cognitive domain, *comprehension* (or *understand*), requires you to interpret, explain, or understand the knowledge. The *application* (or

apply) level involves using information that you remember and understand and can apply in new situations. *Analysis* (or *analyze*) requires recognizing and differentiating relationships between parts and using clinical reasoning and critical thinking skills. *Synthesis* (or *synthesize*) refers to the ability to take several pieces of information or clinical data and use them to make a nursing care judgment or decision. The next level of the cognitive domain is *evaluation* (or *evaluate*). Here, you must check data, critique information, or judge the outcome of nursing care. The final level of the cognitive domain in Bloom's revised taxonomy is *creation* (or *create*). At this level, you must be able to generate new approaches to nursing care or develop a unique nursing care plan based on available information.

TABLE 2.1
Levels of the Cognitive Domain

- **Knowledge/Remember:** Recognizing, recalling
- **Comprehension/Understand:** Interpreting, exemplifying, classifying, summarizing, inferring, comparing, explaining
- **Application/Apply:** Executing, implementing, using knowledge appropriately in new or different situations
- **Analysis/Analyze:** Differentiating, organizing, attributing
- **Synthesis/Synthesize:** Putting parts together to form a whole; using data from several sources to form a conclusion or make a decision
- **Evaluation/Evaluate:** Checking, critiquing, judging against standards or protocols
- **Creation/Create:** Generating, planning, producing

Test items can be written to test at all levels of the cognitive domain, but questions that are written for the NCLEX-RN exam are generally written at application levels and above because nursing requires the ability to apply knowledge to clinical situations, analyze data, think critically, prioritize information, make clinical decisions for client care, evaluate outcomes of nursing interventions or healthcare treatments, and create care plans based on specific client needs. This book and the questions on thePoint present questions at the application level and higher.

Clinical reasoning refers to the higher-order mental activities and critical thinking skills used to solve a problem or make a decision. Nurses use

clinical reasoning, critical thinking, critical synthesis, and clinical decision making and make clinical judgments to provide safe client care.

Understanding the types of test items written at various levels of the cognitive domain and strategies to answer them is key (🔑) to success on the licensing exam. Examples of questions at higher levels of the cognitive domain are provided here to assist you in further understanding the types of questions used on the licensing exam and the strategies you can use to answer them. A summary of the cognitive levels, with examples of question stems and strategies for answering them, is given in [Table 2.2](#).

Application-Level Item

Application-level items test your ability to apply knowledge to a specific scenario. These questions draw on your ability to know and understand nursing content and to then apply this information to a specific scenario or situation (see [Fig. 2.10](#)).

FIGURE 2.10 Sample Application-Level Item

The healthcare provider (HCP) prescribes a serum lithium level tomorrow for a client with bipolar disorder, manic phase, who has been receiving lithium 300 mg PO three times daily for the past 5 days. At what time should the nurse plan to have the blood specimen obtained?

1. before bedtime
2. after lunch
3. before breakfast
4. during the afternoon

Strategies for Answering Application-Level Questions

- Read the question, and consider what information you already know and how that information should be used to answer this particular question.
- Consider how information you can recall should be applied to nursing care for the client that is described in the scenario for the question.
- Apply known formulas (divided dose/drip rate calculation), frameworks (e.g., Maslow's hierarchy, developmental stages, stages of moral development), and procedural steps (how to administer a particular medication) to answer the question posed in the new clinical situation (scenario).
- Double-check your answer by recognizing what information you are applying to answer the question.

Analysis-Level Items

Questions at this level ask you to analyze data, clusters of symptoms, and implementation plans and then make clinical decisions. These questions can also ask about what additional information should be obtained to make a clinical decision or plan care (see [Fig. 2.11](#)).

FIGURE 2.11 Sample Analysis-Level Item

Which statements by the mother of a toddler should lead the nurse to suspect that the child is at risk for iron deficiency anemia? Select all that apply.

- ☐ 1. “He drinks over 4 glasses of milk per day.”
- ☐ 2. “I cannot keep enough apple juice in the house; he must drink over 10 oz (300 mL) per day.”
- ☐ 3. “He refuses to eat more than two different kinds of vegetables.”
- ☐ 4. “He does not like meat, but he will eat small amounts of it.”
- ☐ 5. “He sleeps 12 hours every night and takes a 2-hour nap.”

Strategies for Answering Analysis-Level Questions

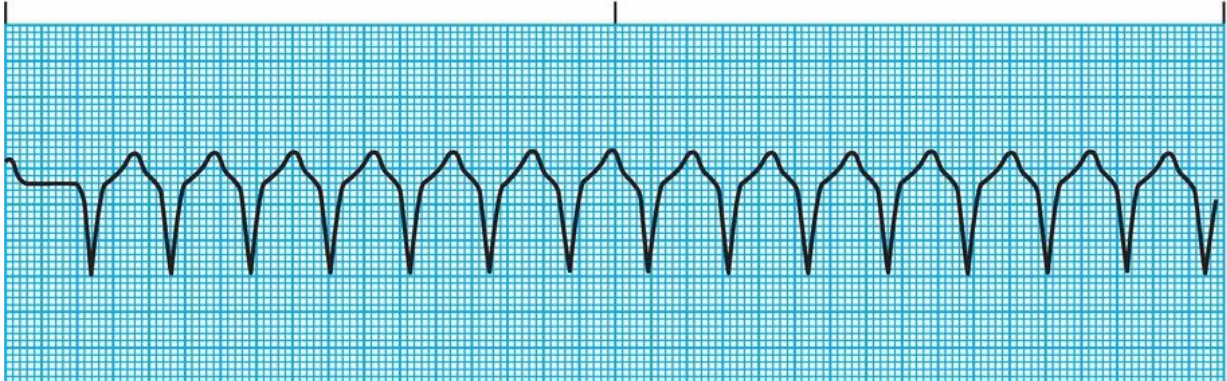

- Identify the data presented in the scenario that lead you to draw a conclusion.
- Identify how the parts are related and how the nurse should assemble them to make a complete care plan.
- Determine if you have sufficient information to make a decision.
- Review data from all sources possible (client’s vital signs, client’s responses to medication and treatments, chart information, client assignment list, etc.).
- Double-check your answer by determining that you have understood all of the components of care and have made the correct nursing decision based on those components.

Synthesis-Level Items

Synthesis-level test items ask you to use several pieces of information to make a clinical decision. The focus here is on obtaining sufficient information to make a clinical decision, rather than analyzing data already available. The information may come from the client/family or members of the healthcare team. In synthesis-level items, you must determine accuracy and usefulness of information for the particular situation, sort relevant data from irrelevant data, and use it to plan or give nursing care (see [Fig. 2.12](#)).

FIGURE 2.12
Sample Synthesis-Level Item

The nurse observes the cardiac rhythm (see below) for a client who is being admitted with a myocardial infarction. What should the nurse do first?

- ☐ 1. Prepare for immediate cardioversion.
- ☐ 2. Begin cardiopulmonary resuscitation (CPR).
- ☐ 3. Check for a pulse.
- ☐ 4. Prepare for immediate defibrillation.

Strategies for Answering Synthesis-Level Questions

- Read the question to determine what information is necessary to provide safe client care.
- Determine if you have sufficient and accurate information.
- Interpret all data obtained in context of the question and the client's needs.

- Make a clinical decision about the relevant nursing action.
- Double-check your answer by being sure that the information you have directs you to the correct answer.

Evaluation-Level Items

Evaluation-level items ask you to make judgments about care, determine the effectiveness of nursing care, or evaluate the extent to which an intended outcome has been achieved. Evaluation-level test items can also ask you to determine if the care given by others (client/family, healthcare team, healthcare provider) is appropriate (see [Fig. 2.13](#)).

FIGURE 2.13
Sample Evaluation-Level Item

A nurse is reviewing the chart of an adult male with cancer. The healthcare provider (HCP) has prescribed filgrastim 400 µg, subcutaneously once daily. The nurse reviews the laboratory report and determines treatment has been effective when:

Laboratory Results

Test	Result
Hemoglobin	12.0 g/dL (120 g/L)
Platelet count	108,000/mm ³ (108×10^9 /L)
WBC count	1,600/mm ³ (1.6×10^9 /L)
ANC	< 1,000/mm ³ (1×10^9 /L)

- ☐ 1. hemoglobin is 16 g/dL (160 g/L).
- ☐ 2. WBC count is 3,500/mm³ (3.5×10^9 /L).
- ☐ 3. platelet count is 200,000/mm³ (200×10^9 /L).
- ☐ 4. RBC count is 4.3 million/mm³ (4.3×10^{12} /L).

Strategies for Answering Evaluation-Level Questions

- Review the question to determine what is to be evaluated. Consider if the question is asking you to verify a client's understanding or if the question is asking if a particular outcome has been attained.
- Before looking at possible answers, consider what is the accepted standard of care, ideal level of care, or intended outcome.
- Match the answers with your understanding of the standard of care.
- Double-check your answer with the scenario and expected standard of care in that scenario.

Creation-Level Items

Creation-level test items require you to use information obtained from a client, family, or clinical situation and develop a new, client-centered, or unique approach to solving the clinical problem. For example, the test items may ask you to develop a plan of care, a discharge plan, or an action plan to manage quality improvement (see [Fig. 2.14](#)).

FIGURE 2.14
Sample Creation-Level Item

The nurse is caring for a client who is 12 weeks pregnant and speaks Spanish only. Which interventions should the nurse include in the plan of care at the client's initial visit? Select all that apply.

- ☐ 1. Provide brochures in the client's native language.
- ☐ 2. Refer the client to a high-risk clinic.
- ☐ 3. Discuss cultural differences, and emphasize the differences between cultures.
- ☐ 4. Arrange for an interpreter for her appointments.
- ☐ 5. Discuss contraception and options.
- ☐ 6. Review dietary intake and discuss nutrition.

Strategies for Answering Creation-Level Test Questions

- Read the question to determine what is to be developed or created.
- Consider all of the elements necessary to have a complete plan of care, discharge plan, etc.
- Understand what is and is not appropriate to include in the plan being created, and rule out inappropriate aspects of care for the client or situation presented in the scenario.
- Double-check your answer by reviewing the appropriateness of each of the elements in the plan you have developed.

Table 2.2

Keys to Answering Test Questions from Various Levels of the Cognitive Domain

Cognitive Level	Descriptions	Examples of Question Stems	Strategies for Answering Questions
Application	Transfer knowledge from classroom to clinical practice.	To assess the breath sounds for a client with heart failure, where should the nurse place the stethoscope?	Use knowledge and understanding of how to auscultate breath sounds to assess a particular client.
	Use a formula or guidelines to perform calculations.	The client is to receive 1,000 mL of fluids in 8 h. The intravenous administration set delivers 15 drops per minute. The nurse should regulate the infusion to provide how many milliliters per minute?	Apply appropriate formula to calculate an intravenous fluid drip rate.
	Apply knowledge and understanding to new situations.	Which nursing intervention is appropriate for this client?	Use knowledge and understanding about nursing interventions, and apply to the client's particular situation.
		The nurse should instruct the client about which side effects that may occur when the client takes this drug? Select all that apply.	Apply knowledge and understanding about drug side effects to instruct a particular client.
Analysis	Organize clinical data into relevant parts in order to identify a client need, form a conclusion, or make a clinical decision.	The nurse is teaching a client to use a metered-dose inhaler. In which order (from first to last) should the nurse instruct the client about the steps to take to use the inhaler? All options must be used.	Use knowledge and understanding of correct order of a skill or procedure to teach a particular client.
		The nurse is communicating with an agitated client. Which communication technique is most appropriate?	Use knowledge and understanding of communication techniques to apply to this particular client.
	Review all data to determine if sufficient data are available to make a decision.	Based on the clinical assessment, the nurse determines the client has which need?	Review the client's signs and symptoms to determine an appropriate nursing problem.
	Analyze data to determine priorities.	Which (data) indicate (s) the need for nursing action?	Analyze data to determine which nursing action to take next.
	Distinguish relevant from irrelevant data.	Which client should the nurse care for first ?	Organize information about a group of clients, and determine which client requires nursing care first.
	Determine what data are needed to plan or implement care.	Which (data) indicate (s) the nurse should assess the client further?	Analyze data, and determine if additional data are needed.
		Based on these findings, the nurse determines the client is in xxx stage of development.	Analyze data/findings, and determine appropriate stage (of development).
		Which client is at risk for xxx?	Analyze data about a group of clients with risk factors and determine the client's risk.
		The client is expressing concerns about xxx and the nurse observes xxx behaviors. The nurse should (do/say/refer):	Analyze clients' verbal and behavioral responses to determine what to say to the client.

Synthesis	Assemble information from several sources to determine the best course of action.	After reviewing (data from the client and the chart), what should the nurse do first ?	Use information from a variety of appropriate sources such as the client, client responses to medical and nursing interventions, laboratory data, diagnostic tests, and progress notes to determine appropriate nursing action.
		Based on this information (about side effects of medication) and the client's current health status, the nurse should instruct the client to xxx?	
Evaluation	Make judgments about the effectiveness of nursing care. Use standards of care to determine the extent to which the client has met them. Critique care given by others.	After assessing the client, the nurse reviews the healthcare provider's prescriptions. The nurse should perform which action first ?	Determine if the client understands the instructions based on the criteria established in the teaching plan. Evaluate effectiveness of a nursing intervention, drug, or treatment based on the intended or expected outcome. Evaluate appropriateness of care given by others according to standards of care and knowledge of scope of practice. Judge effectiveness of outcome of a nursing action (administering a drug) based on expected therapeutic effect.
		After reviewing the client's rhythm strip, pain medication record, and vital signs chart, what should the nurse do next ?	
		Which statement indicates the nurse's best response to the child's parent?	
		Which statement indicates the client has understood the nurse's teaching?	
Creation	Create or develop a unique or individualized plan, report, or protocol based on client needs.	Which finding indicates the intended therapeutic effect has occurred?	Develop a discharge plan. Individualize a standardized care plan for a specific client. Create a care management plan for a group of clients and a team of healthcare professionals. Create a detailed report about the client's health status.
		The nurse is observing an unlicensed assistive personnel (UAP) turn a client. Which observation indicates the nurse should intervene?	
		The nurse has administered nitroglycerin to a client with chest pain. In 30 seconds, the client's chest pain should be:	
		Which instructions should be included in a discharge plan for the client? Select all that apply.	
		Which nursing actions best meet this client's needs?	
		The nurse is planning care for six clients. The staffing for the team includes one registered nurse (RN) and one unlicensed assistive personnel (UAP). Which clients should be assigned to the UAP? Select all that apply.	
		The nurse is gathering information for a "hand off" for transferring the client from one nursing unit to another. The nurse should include which information in the report? Select all that apply.

3 How to Prepare for and Take the NCLEX-RN® and Other Nursing Exams

Introduction

Studying for the NCLEX-RN or other similar exams requires careful planning and preparation. Evidence from studies about how students prepare for exams indicates that the students who do best on exams have done three things: (1) learned the content in a way that they can apply it to nursing practice (deep learning), (2) learned how to control their anxiety, and (3) fine-tuned their test-taking skills (Thomas & Baker, 2011). This chapter provides information about each of these factors associated with exam success.

You can begin developing your study preparation using a systematic approach to study that includes these five steps to test for success:

- Assess your study needs.
- Develop a study plan.
- Refine your test-taking strategies.
- Rehearse test anxiety management skills.
- Evaluate progress on a regular basis.

Use these five steps as you take your first test in nursing school. Refine your test-taking strategies as you evaluate your progress at each step of the way, so that when you are ready to take the licensing exam, you will be an experienced and successful test taker. Use the Personal Study Plan in Table 3.1 to help develop your own study plan.

Assessing Study Needs

The first step toward test success is to determine your strengths and limitations. Even students who have been successful throughout their academic life, and nurses who are excellent caregivers, have areas in which they need improvement. Be honest with yourself as you assess your own study needs. These steps can help you in your assessment:

- *Review your success in your nursing program.* Review your grades in

science courses and the courses in the nursing curriculum. Success on the NCLEX-RN tends to correlate with grades (grade point average) achieved in science and nursing courses. Subjects in which you received high grades, that you found easy to learn, or in which you have had additional clinical practice or work experience are likely to be areas of strength. On the other hand, subjects you found difficult to learn (or in which you did not achieve high grades) should be areas for concentrated review. Also consider content areas that you have not studied for a while. Recent course work will be the most familiar and, therefore, may require the least amount of study. Candidates should have a strong mastery of materials learned in fundamental skills or assessment courses which are typically offered early in a program. All students, even students who have achieved success in nursing courses, benefit from identifying areas requiring study and spending time practicing test-taking skills. You also can use the practice exams in this book to identify areas needing further study. Begin with the subjects you find most difficult or in which you have the least confidence.

- *Assess your test-taking skills.* Using effective test-taking skills contributes to exam success. What have you done in the past to make you confident about taking a test? How do you feel when you are in the exam situation? What has worked in the past to help you be successful? Review these strategies to build on past successes and work on problem areas. Consider additional strategies suggested in the section “Refining Your Test-Taking Strategies,” page 35. You can practice these skills by simulating the testing situation using the practice tests and comprehensive exams in this review book.
- *Assess your ability to take tests that require application, analysis, and evaluation.* Test questions used on the licensing exam are written at higher levels of the cognitive domain. Many candidates’ experience with taking tests has come from taking “teacher-made” tests—tests developed by the faculty at your school of nursing. These tests are commonly written to test students’ knowledge and understanding of course content and may not include questions that require application, analysis, or evaluation of course material. Additionally, several of the types of alternate-format questions have recently been added to the exam, and nursing faculty may not yet be designing their own test questions using these formats. Finally, some

students are able to “second-guess” the teacher and use this ability to their advantage when taking teacher-made classroom tests. However, it is not as easy to anticipate test questions on standardized and licensing exams, and you will need to develop skills that will help you think critically when presented with an unfamiliar situation. As you prepare to take the licensing exam, spend time on questions where you need to “figure out” the best approach to answering the question. You can use the questions in this book and on thePoint to be sure you understand the difference between questions that require only recall and understanding and those that require you to apply information to provide client care, make clinical judgments, and initiate nursing actions. Use the *Content Mastery and Test-Taking Skill Self-Analysis* table in the back of this book to identify your ability to answer questions in the higher levels of the cognitive domain.

TABLE 3.1
Personal Study Plan

Assess Study Needs

1. Review your success in nursing school.

- ☐ I did best in these courses:

- ☐ I needed to study harder in these courses:

- ☐ I took these courses near the beginning of the curriculum:

- ☐ I scored best on these practice exams in this book:

- ☐ I am not satisfied with my scores on these practice exams in this book:

- ☐ I need further study in these content areas:

- ☐ I need further study in these areas of the nursing process:

- ☐ I need further study in these areas of client needs:

2. Review your test-taking skills.

- ☐ I can identify the components of a test question.
☐ I read questions carefully before answering.
☐ I can make reasonable guesses if I am not certain of the correct answer.

3. I can recognize patterns of why I miss questions.

4. I can pace myself to complete questions in the allotted time.

5. Review your test-anxiety management skills.

- ☐ I can do relaxation and deep-breathing exercises.
☐ I can visualize success.
☐ I can give myself positive feedback.
☐ I can concentrate for extended periods of time.

6. Review your computer skills.

- ☐ I am able to use a computer to read and answer test questions.
☐ I have used thePoint Web site accompanying this book.

Develop a Study Plan

- ☐ I will study in this location:

- ☐ I will study at these times and dates:

- ☐ I have assembled all of the materials I need to study:

- ☐ I will study with a study group:

Evaluate Progress

- ☐ I have completed the practice tests in this book.
☐ I have completed the comprehensive tests in this book.
☐ I need to improve my scores in these areas:

- ☐ I am prepared to take the NCLEX-RN examination.

- *Assess your English language skills.* Persons for whom English is an additional language or who do not have well-developed reading and comprehension skills may require additional practice in reading and answering NCLEX-RN-style test questions. If you are one of these persons, plan additional time to practice reading and answering questions, to time yourself when answering questions, and to validate that you understand the question correctly. If necessary, seek assistance. As you study, keep a list of words you do not understand and practice using them.
- *Assess your ability to take timed tests.* Are you always the last one to finish a test? Do you request additional time to complete a test? If so, you will want to practice taking timed tests and doing your best, while completing as many questions as possible. The licensing exam is designed to be completed in 6 hours; only questions completed within that time frame will

be scored. As you use the practice questions and tests in this book, time yourself and, if needed, determine ways that you can increase your speed without sacrificing accuracy. The comprehensive tests in this book have been intentionally designed with the minimum and maximum number of operational questions on the licensing exam; time yourself as you take these tests. A typical response time on the exam is under 2 minutes per question. Comprehensive tests in part 3 of this book represent the range of number of questions a candidate might receive offering you an opportunity to time yourself taking exams with the minimum and maximum number of questions.

- *Assess your skills for taking computer-administered exams.* Although previous computer experience is not necessary to take the NCLEX-RN, you should familiarize yourself with the differences between taking a paper-and-pencil exam and taking exams administered by the computer. If you have not used a computer before, find a learning resource center at your college, university, library, or hospital where you can become familiar with basic computer keyboard skills. thePoint, which simulates the computerized NCLEX-RN, offers you the opportunity to practice taking computer-administered test questions. Use these questions to practice reading questions from the computer screen and become acquainted with answering questions in a computerized format. If you are accustomed to underlining key words or making notes in the margins of paper-and-pencil tests, adapt these strategies to reading and answering the questions on the computer screen. Also be sure that you can use a drop-down calculator to answer questions requiring the use of math skills. Use the tutorial offered by the testing company, Pearson VUE at <http://www.pearsonvue.com/nclex/>, to learn how the test questions will be computer-administered. Note, you cannot move to the next question without answering the question presented on the screen, and you are not able to return to review questions once you have moved to the next question.
- *Assess your reason(s) for not answering the test question accurately.* There are many reasons why students select an incorrect answer. These could include not reading the question carefully (not reading all of the words in the sentence; missing key words), not reading the options carefully, not

knowing the answer (lack of knowledge or deep learning), not recognizing the rationale for the correct answer, guessing, not being rested, or dealing with health problems when taking the exam. The most important thing you can do is to assess the *reason* why you are not answering questions correctly. Recent evidence about test taking indicates that understanding the *pattern* of missed questions is essential to changing how you study (Wiles, 2015). For this reason, we have designed the *Content Mastery and Test-Taking Skill Self-Analysis* table (see Table 3.2) so you can identify your specific reason(s) for not answering the questions correctly. Total the check marks in the columns to identify patterns of reasons for not answering the questions correctly. Determine if there is a pattern, and use this information to plan your study. Consider discussing the findings with your faculty member for suggestions for improving your test-taking skills. There is a tear-out copy of the *Content Mastery and Test-Taking Skill Self-Analysis* table (at the back of the book) that you can copy and use for *each* test in this book.

- *Assess your risk for not passing the licensing exam.* Recent evidence indicates that factors associated with not passing the licensing exam can be identified (Breckenridge, Wolf, & Roszkowski, 2012). Table 3.3 lists these factors; having more factors is associated with higher risk. Note that the three top risk factors are poverty, low science GPA prior to the nursing major, and repeating college science courses and, when summed, are predictors of exam failure (Breckenridge et al., 2012). It is important that you identify your risk for not passing the licensing exam and take advantage of all resources available to assist you to lower your risk. Interventions include forming study groups, attending review sessions, establishing effective study habits, practicing test taking on a regular basis, determining reasons for not answering questions correctly (use the *Content Mastery and Test-Taking Skill Self-Analysis* table in this book), and taking action steps to improve knowledge of nursing content and test-taking strategies. The earlier in the academic program that you can identify your risk, use interventions, and monitor your progress, the more likely you are to reverse your risk and improve your chance of passing!

TABLE 3.2

Content Mastery and Test-Taking Skill Self-Analysis

and why, and then total each column. The reasons for not answering the question.

Review Strategies

Test Number	Subject (care of childbearing family, care of children, care of adults, care of clients with psychiatric disorders and mental health problems)	Score
-------------	--	-------

Total number of questions missed:

Use the chart below to identify the subject matter and the reason you missed the question. Use the following codes to note the client need area of the question you missed:

MC, management of care; SI, safety and infection control; HM, health promotion and maintenance; PA, physiological adaptation; PI, psychosocial integrity; PP, pharmacological and parenteral therapies; RR, reduction of risk potential; BC, basic care and comfort.

- How many questions in each area of client needs did you miss?
- How does this compare with other exam results from this review?

Lower _____ Same _____ Higher _____ NA _____

If you missed questions because you misread questions, missed key words, or changed answers, review *Lippincott Q&A Review for NCLEX-RN Part I*.

If you missed questions because you did not remember or understand the content, review that content in *Lippincott Q&A Review for NCLEX-RN Part II* and your other nursing references.

If you missed questions because you guessed, were you missing because of “rapid guessing” to complete the test on time, or because of “random guessing,” making a reasoned attempt to answer the question? Consider how you will approach “guessing” when you do not know the answer.

If you missed questions because you did not pace yourself, practice taking timed test questions and pacing yourself to allow sufficient time for all questions.

What is the pattern of the types of questions you are missing?

What is your action plan for further study?

TABLE 3.3
Factors Associated with Risk of Failure on NCLEX-RN

- Income at or below poverty level
- Science GPA (low grades in science courses—biology, chemistry, microbiology)
- Repeating college science courses
- English is second language
- Low score on standardized admission tests (SAT, ACT)
- Low score on standardized progression tests (ATI, HESI)
- Failure of one or more nursing prerequisite courses (more courses, higher risk)
- Failure of one or more nursing courses (more courses, higher risk)
- GPA (<3.0)
- Working (more hours worked, higher risk)
- Lack of sufficient support to care for children while in school or studying
- First in family to attend college

Developing a Study Plan

Once you have identified areas of strength and areas needing further study, develop a specific plan and begin to study regularly. Students who study a small amount of content over a longer period of time tend to have higher success rates than do students who wait until the last few weeks before the exam and then “cram.” Consider these suggestions:

- *Identify a place for study.* The area should be quiet and have room for your books and papers or electronic study materials. Do not study while playing music, responding to text messages, or listening to the television; background noise is distracting and will not be allowed at the actual NCLEX-RN testing site. Your area for study might be in your home, at your nursing school, at your workplace, or in a library. Be sure your friends and family understand the importance of not interrupting you when you are studying.
- *Establish regular study times.* Make appointments with yourself to ensure a commitment to study. Frequent, short study periods (1 or 2 hours) are preferable to sporadic, extended study periods. Test yourself often by taking test questions or generating test questions yourself; using practice test questions is more effective than rereading your textbooks or notes (Shellenbarger, 2011). Plan to finish your studying 1 week before the NCLEX-RN; last-minute cramming tends to increase anxiety.

- *Obtain all necessary resources.* As you begin to study, it is helpful to have easy access to textbooks, electronic resources, notes, and study guides.
- *Make the best use of your time.* Make review cards that you can carry with you to study during free moments throughout the day. Some students record review notes and listen to the tapes or podcasts while driving or exercising. Use electronic devices and smartphones to add test review “apps” to practice test questions on a regular basis.
- *Reduce or eliminate stressful situations.* Students who are juggling multiple responsibilities (such as working, managing a family, taking courses, planning a wedding, or caring for elderly parents) may find it difficult to find time to study or to concentrate when studying. Managing a variety of stressful situations puts students at risk for failing exams. If possible, reduce the number of stressful situations you are involved in during the time you are preparing to take the NCLEX-RN exam.
- *Develop effective study skills.* Study skills enable you to acquire, organize, remember, and use the information you need to take the NCLEX-RN. These skills include outlining, summarizing, applying, synthesizing, reviewing, and practicing test-taking strategies. Some students make concept maps or use reflective journaling to help them learn and remember important content. Use these study skills each time you prepare for an exam.
- *Use study skills with which you are familiar and that have worked well for you in the past.* Recall effective study behaviors that you used in nursing school, such as reviewing highlighted text, outlines, or content/concept maps.
- *Study to learn, not to memorize.* The NCLEX-RN tests application and analysis of knowledge. When reviewing content, continually ask yourself, “How is this information used in client care?” “What clinical decision making will be required of this information?” and “What is the role of the nurse in using this information?” Being able to apply information, rather than just being able to list or recognize information, is one of the most important study skills to master. Study for “deep learning,” not surface learning, which emphasizes only comprehension and short-term recall.
- *Identify your learning and study-style preferences.* Each student has a preferred way of learning. For example, some students prefer learning

material by listening; they are considered *auditory* learners. If this describes your preference, you will benefit from reviewing recorded notes or class lectures. Some students learn best in a visual mode. They learn by reading, reviewing slide presentations, or looking at illustrations. For these *visual* learners, reading and looking at images is helpful. *Kinesthetic* learners, those who like to touch and manipulate to learn, benefit from working with models and manikins to reinforce their learning. While you likely have one learning style and study preference, using a variety of styles will enhance the study experience.

- *Affirm your language skills.* If English is not your first or only language, focus on developing your language skills (Hansen & Beaver, 2012). Make note cards of words that are unfamiliar or keep a list of words from practice tests that you do not know, and review these words. Study with a friend for whom English is the native language, and discuss practice questions to understand meaning of the words and the nursing context. Using concept maps is another useful strategy when studying about particular health problems.
- *Consider forming a study group.* Some students prefer to study alone, whereas others benefit from study groups; know which approach works best for you, and develop your study plan accordingly. If you participate in a study group, limit the group size to about seven people. The group should develop norms for working together that focus on understanding and applying nursing content, rather than memorizing facts. Talking out loud about the thought processes that go into answering a question is a helpful approach, particularly when students or faculty can provide corrective feedback. In a study group, students can pose questions to each other and discuss rationale or divide the topics for review and practice, but every member must come prepared to contribute. If your school has software that allows you to form online groups of students, set up a study forum. Some students study with a “study buddy.” With just two people, it is easy to use Skype or other technology that permits seeing the person with whom you are studying.
- *Attend faculty-led test review sessions.* Most faculty provide opportunities for group or individual review after each test. Attend these sessions or ask to discuss your exam scores with your faculty. Interaction with faculty and

advisors about your test-taking skills is an important element to success on nursing exams and has been shown to improve course grades (Wiles, 2015). Determine the reasons for and patterns of missing particular questions, and plan to use this information in your study plan.

- *Study the most difficult material before bedtime.* Research indicates that sleeping consolidates information in your memory (Shellenbarger, 2011).
- *Anticipate questions.* As you study, formulate questions around the content. Practice giving a rationale for your answer to these questions. If you work in a study group, have each member contribute questions that the entire group answers. Frequent testing solidifies learning.
- *Study common, not unique, nursing care situations.* The NCLEX-RN tests minimum competence for nursing practice; therefore, focus on common health problems and client needs. Review the *RN Practice Analysis*, published by the National Council of State Boards of Nursing, and the - current licensing exam test plan to determine common nursing care activities. Both can be found at the NCSBN Web site at ncsbn.org.
- *Study broad concepts, rather than insignificant details.* Be sure you understand the underlying pathophysiology and nursing implications across the life span for broad concepts such as oxygenation, perfusion, comfort, delegation, and so on. Answers to test questions can be derived from understanding the basic concept and then determining how to implement nursing care for specific client needs.
- *Simulate test taking.* The comprehensive tests in Part Three of this book are designed to simulate the random order in which questions appear in the NCLEX-RN and the possible number of question you might receive. Make additional copies of answer sheets, and retake the exams on which you had low scores. Use the *Content Mastery and Test-Taking Skill Self-Analysis* table (see Table 3.2 and at the back of the book) to review the *reason* you have missed a question and note *patterns* that may become evident, and use these to guide further study.

Refining Your Test-Taking Strategies

Knowing how to take a test is as important as knowing the content being tested. Strategies for taking tests can be learned and used to improve test

scores. Here are some suggestions for building a repertoire of effective test-taking strategies:

- *Understand the type of test item, the cognitive level, and related thinking processes.* (See Chapter 2 for more information on question types and cognitive levels found on the NCLEX-RN exam.)
- *Understand which integrated process* (step of the nursing process, caring, communication, documentation, teaching/learning, culture and spirituality) *is being tested.* For example, as you read the question, determine whether the question is asking you to set priorities (planning) or judge outcomes (evaluation).
- *Understand client needs.* As you read the question, consider the question in the context of client needs. Be sure to understand if the question is asking you to determine what to do “**first**” or to select the nursing action that is “**best**.”
- *Understand the age of the client, if noted in the test question.* If relevant to answering the question, the age of the client will be specified; consider what information about that age-group will be important to answering the question. If the age of the client is not specified, assume that the client is an adult and base your answers on principles of adult growth and development.
- *Read the question carefully.* This is one of the most important aspects of effective test taking. Read the stem carefully; do not rush. Ask yourself, “What is this question asking?” and “What is the expected response?” If necessary, rephrase the question in your own words, but do not change the meaning of the question when putting the question in your own words, as this is one of the reasons for obtaining an incorrect response.
- *Do not read meaning into a question that is not intended, and do not make a question more difficult than it is.* If you do not understand the question, try to figure it out. If, for example, the question is asking about the fluid balance needs of a client with pheochromocytoma and you do not remember what pheochromocytoma is, then try to answer the question based on your knowledge of the concept of fluid balance.
- *Base your answer to a question on evidence for best nursing practice.* The exam questions reflect national nursing practice standards and are not

written to test knowledge of procedures or practices at specific healthcare agencies. Thus, it is important to answer the question from the framework of best nursing practice, not unique practices or procedures that are specific to one clinical agency. For example, “code blue” may be a specific term for a cardiac arrest in one agency, but not in another, or there may be specific steps in the procedure for intravenous line care at each agency. When answering the question, refer to evidence-based practices more than your personal clinical experiences.

- *Determine if the question is asking you to set priorities or place steps of a procedure in a particular order.* Read the stem of the question carefully, and be clear about the priority (first, last) or order (first, last) in which you are to answer the question. Base your answer on commonly used nursing frameworks for setting priorities, such as the nursing process: assess, plan, implement, and evaluate; Maslow’s hierarchy of needs: physiological, safety and security; love and belonging, self-esteem; and self-actualization; principles of emergency care: breathing, bleeding, and circulation; principles of triage: resuscitation, emergent, urgent, less urgent, and nonurgent; fire response priorities: rescue, alarm, confine, and extinguish; role of the nurse versus role of the primary care provider versus role of the licensed practical/vocational nurse (LPN/VN) and unlicensed assistive personnel (UAP); or procedures for delegation: scope of practice, workload, ability, and follow-up.
- *Look for key words that provide clues to the correct answer.* For instance, words such as “except,” “not,” and “but” can change the meaning of a question; words such as “first,” “next,” and “most” ask you to establish a priority or use an order or sequence of steps; key words such as “most likely” or “least likely” are asking you to determine a probability of a successful outcome. When the question asks you to “select all that apply,” be sure you are considering each option as having the possibility of being correct, and have ruled out the ones you have not selected as being incorrect.
- *Be certain you understand the meaning of all words in the question.* If you see a word you do not know, try to figure out its meaning from a familiar base of the word or from the context of the question.
- *Attempt to answer the question before you see the answers, and then look*

for the answer(s) that is/are similar to the one(s) you generated. If you do not see the answer you thought was correct, stop and reread the question, be sure you understand what the question is asking, and determine what will help you choose the correct answer.

- *Eliminate answers that you know are not correct.* This will improve your chances of selecting the correct answer. Treat each option in multiple-response questions as “true” or “false”; this will help eliminate incorrect answers.
- *Base answers on nursing knowledge.* Remember that the NCLEX-RN is used to test for safe practice and that you have learned the information needed to answer the question.
- *If you do not know an answer, make a reasonable guess.* Hunches and intuition are often correct. Do not waste time and energy; give yourself permission to not know every question, and move on to the next one. In the computerized adaptive testing format of the NCLEX-RN test, you must answer each question before the next item is administered, and because the level of difficulty will be adjusted as you answer each question, it is likely that you will know the answer to one of the next questions.
- *Learn to pace yourself.* Pacing has been noted to be an important test-taking skill (Thomas & Baker, 2011). Pacing involves spending an appropriate time on each question as well as monitoring the overall amount of time during the test so that you are not rushing at the end. Some students, when they realize they are running out of time, tend to do “rapid guessing,” that is, making quick decisions in order to answer more questions. This approach leads to answering with an incorrect response. “Random guessing” on the other hand is a more strategic approach in which you think carefully and make a reasonable guess based on information you can recall to help you answer the question. Pacing also involves recognizing when you need a break. Attention span and concentration levels can start to decline in about 45 minutes, and you should request a break when needed (Wiles, 2015). *Use the comprehensive tests in this book to time yourself and develop an appropriate pace for taking the test.*

Strategies for Managing Test Anxiety

All test takers experience some anxiety. A certain amount of anxiety is motivating; extreme anxiety contributes significantly to poor test performance by causing test takers to change answers, lose concentration, misread or misunderstand questions, or become unable to control the pace of their response to the questions. Be prepared to control unwanted anxiety using the suggestions below.

Anxiety can be managed by both physical and mental activities. Practice anxiety management strategies while you are taking the comprehensive examinations in this book, and use them with *each* exam you take in school or elsewhere. Practicing managing test anxiety when taking “low-stakes” tests, such as practice tests and classroom tests, will make managing test anxiety much easier when you are taking the “high-stakes” tests, such as course or program final exams and, of course, the licensing exam. Commonly used anxiety management strategies include:

- *Mental rehearsal.* Mental rehearsal involves reviewing the events and environment during the examination. Anticipate how you will feel, what the setting will be like, how you will take the exam, what the computer screen will look like, and how you will talk to yourself during the exam. To see an example of a testing center, go to the Pearson VUE Web site, and use the video to take a tour of a typical test center (<http://home.pearsonvue.com/test-taker/Pearson-Professional-Center-Tour.aspx>). Rehearse what you will do if you have test anxiety.
- *Relaxation exercises.* Relaxation exercises involve tensing and relaxing various muscle groups to relieve the physical effects of anxiety. Practice systematically contracting and relaxing muscle groups from your toes to your neck to release energy for concentration. You can do these exercises during the exam to promote relaxation. Smile! Smiling relaxes tense facial muscles and reminds you to maintain a positive attitude.
- *Deep breathing.* Taking deep breaths by inhaling slowly while counting to 5 and then exhaling slowly while counting to 10 increases oxygen flow to the lungs and brain. Deep breathing also decreases tension and helps manage anxiety by focusing your thoughts on the breathing and away from worries.
- *Positive self-talk.* Talking to yourself in a positive way serves to correct negative thoughts (e.g., “I cannot pass this test” and “I do not know the

answers to any of these questions”) and reinforces a positive self-concept. Replace negative thoughts with positive ones, for example, tell yourself, “I can do this,” “I studied well and am prepared,” or “I can figure this out.” Visualize yourself as a nurse—you have passed the test!

- *Distraction.* Thinking about something else can clear your mind of negative or unwanted thoughts. Think of something fun, something you enjoy. Plan now what you will think about to distract yourself during the exam.
- *Concentration.* During the exam, be prepared to concentrate. Have tunnel vision. Do not worry if others finish the test before you. Remember that everyone has his or her own speed for taking tests and that each test is individualized. Do not rush; you will have plenty of time. Focus; do not let noises from the keyboard next to you divert your attention. Do not become overwhelmed by the testing environment. Use positive self-talk as you begin the exam. Some students become bored during the exam and then become careless as they answer questions toward the end of the exam. Practice taking tests of at least 265 questions, and discover how long you can focus your attention on the test questions. Practice taking breaks if you begin to lose your concentration. During the actual test, be sure to take breaks when you need them.
- *Seek help.* If you find that you are not able to manage your test anxiety, consult your faculty or resources on your campus. Consider obtaining professional help if needed.

Evaluating Your Progress

The last step of your study plan is to check your progress. Review all of your responses using the tear-out *Content Mastery and Test-Taking Skill Self-Analysis* table (at the back of the book) to identify the number of incorrect responses, the reasons for not answering the question correctly, and how many questions in any one clinical area or categories of client needs you have missed. Note if your scores on the practice and comprehensive tests improve. Do not spend time on content you have mastered, on areas in which you obtained high scores on the practice exam, or on areas with which you feel confident. Use the results of your evaluation to set priorities for study on

areas needing additional review. As noted above, evaluate your study skills, your test-taking abilities, and the use of test anxiety management strategies as you take *each* test throughout your academic program. Doing so now will prepare you to test for success.

Tips from Students Who Have Passed the NCLEX-RN®

Students who have successfully passed the NCLEX-RN offer these tips for preparing for, and taking, this exam:

- Study regularly several months before taking the exam. Be sure you are well prepared. Accept responsibility for your study plan—being prepared is up to you!
- Practice taking randomly generated test questions. Most students are accustomed to taking teacher-made exams that cover several topics in the same content area. When taking the NCLEX-RN examination, however, each question will come from a different topic or content area, and you will need to be prepared to shift your focus to a different practice area for each question.
- Use practice questions until you can score at least 75% on the exam. Use practice exams with at least 2,000 questions so you test yourself with a wide range of content and types of questions.
- Use a timer to determine how many questions you can answer in a specified amount of time. Use the timer to be sure you are keeping a steady pace, but not rushing through the test.
- Schedule to take the exam when YOU are ready, but as soon after graduation as is feasible (National Council of State Boards of Nursing, 2007). Candidates who take the exam before they are prepared are not as successful. You are in control of when you take the exam!
- Make sure you know the date, time, and place the exam will be given; how to get to the exam site; how long it takes to drive there; and where you can park. Do locate the exam site, drive to it, and see the room where the exam will be given. Exam sites may be located in small offices in shopping centers and could be difficult to find.
- Visualize yourself in the room taking the test. Use mental rehearsal to

practice anxiety-managing strategies.

- Organize the information you will need to bring to the testing center the night before the exam. You will need to present your Authorization to Test. You will also need to provide required identification.
- Make sure you are physically prepared. Get enough rest before the examination; fatigue can impair concentration. If you work, it may be advisable not to work the day before the exam; if you work on a shift that is different from the time of the exam, adjust your work schedule several days ahead of time.
- Avoid planning time-consuming activities (e.g., weddings, vacation trips) immediately before the exam.
- Do not use any drugs you usually do not use (including caffeine and nicotine), and do not use alcohol for 2 days before the exam.
- Eat regular meals before the exam. Remember that high-carbohydrate foods provide energy, but excessive sugar and caffeine can cause hyperactivity. Experts recommend that prior to taking a test, test takers eat high-fiber, high-carbohydrate foods that are slow to digest, such as oatmeal. Eating well-balanced meals the week before the test is also helpful; the diet should include fruits and vegetables; avoid meals high in meat, eggs, and cheese (Shellenbarger, 2011).
- Dress comfortably, in layers that can be added or removed according to your comfort level.

The authors of this review book offer you our best wishes for success on all of the exams you will be taking throughout your academic career. We are confident that your review and preparation have given you a good foundation for a positive testing experience!

PART 2 Practice Tests

1 The Nursing Care of the Childbearing Family

TEST

1

Antepartal Care

- The Preconception Client
- The Pregnant Client Receiving Prenatal Care
- The Pregnant Client in Birth Preparation Classes
- The Pregnant Client with Risk Factors
- Managing Care, Quality, and Safety for Childbearing Clients
- Answers, Rationales, and Test-Taking Strategies

The Preconception Client

1. A client has obtained levonorgestrel as emergency contraception. After unprotected intercourse, the client calls the clinic to ask questions about taking the contraceptives. The nurse realizes the client needs further explanation when she makes which statement?

- ☐ **1.** “I can wait up to 4 days after intercourse to start taking these to prevent pregnancy.”

- ☐ 2. "My boyfriend can buy levonorgestrel from the pharmacy if he is over 18 years old."
- ☐ 3. "The birth control works by preventing ovulation or fertilization of the egg."
- ☐ 4. "I may feel nauseated and have breast tenderness or a headache after using the contraceptive."

2. An antenatal G2, T1, P0, A0, L1 client is discussing her postpartum plans for birth control with her health care provider (HCP). In analyzing the available choices, which factor has the **greatest** impact on her birth control options?

- ☐ 1. satisfaction with prior methods
- ☐ 2. preference of sexual partner
- ☐ 3. breast- or bottle-feeding plan
- ☐ 4. desire for another child in 2 years

3. Which information would be important to include in the teaching plan for the client who wants more information on ovulation and fertility management?

- ☐ 1. The ovum survives for 96 hours after ovulation, making conception possible during this time.
- ☐ 2. The basal body temperature falls at least 0.2°F (0.17°C) after ovulation has occurred.
- ☐ 3. Ovulation usually occurs on day 14, plus or minus 2 days, before the onset of the next menstrual cycle.
- ☐ 4. Most women can tell they have ovulated because of severe pain and thick, scant cervical mucus.

4. Which instructions about activities during menstruation would the nurse include when counseling an adolescent who has just begun to menstruate?

- ☐ 1. Take a mild analgesic if needed for menstrual pain.
- ☐ 2. Avoid cold foods if menstrual pain persists.
- ☐ 3. Stop exercise while menstruating.
- ☐ 4. Avoid tampons until you have had your periods for 1 year.

5. After conducting a class for female adolescents about human

reproduction, the nurse concludes teaching has been effective when a student makes which statement?

- ☐ 1. "Under ideal conditions, sperm can reach the ovum in 15 to 30 minutes, resulting in pregnancy."
- ☐ 2. "I will not become pregnant if I abstain from intercourse during the last 14 days of my menstrual cycle."
- ☐ 3. "Sperms from a healthy male usually remain viable in the female reproductive tract for 96 hours."
- ☐ 4. "After an ovum is fertilized by a sperm, the ovum contains 21 pairs of chromosomes."

6. A 20-year-old nulligravid client expresses a desire to learn more about the symptothermal method of family planning. Which information would the nurse include in the teaching plan?

- ☐ 1. This method has a 50% failure rate during the first year of use.
- ☐ 2. Couples must abstain from coitus for 5 days after the menses.
- ☐ 3. Cervical mucus is carefully monitored for changes.
- ☐ 4. The male partner uses condoms for significant effectiveness.

7. Before advising a 24-year-old client desiring oral contraceptives for family planning, the nurse would assess the client for which signs and symptoms?

- ☐ 1. anemia
- ☐ 2. hypertension
- ☐ 3. dysmenorrhea
- ☐ 4. acne vulgaris

8. After instructing a 20-year-old nulligravid client about adverse effects of oral contraceptives, the nurse determines that further instruction is needed when the client states which as an adverse effect?

- ☐ 1. weight gain
- ☐ 2. nausea
- ☐ 3. headache
- ☐ 4. ovarian cancer

9. Which information would the nurse include in the teaching plan for a

32-year-old female client requesting information about using a diaphragm for family planning?

- ☐ 1. Douching with an acidic solution after intercourse is recommended.
- ☐ 2. Diaphragms should not be used if the client develops acute cervicitis.
- ☐ 3. The diaphragm should be washed in a weak solution of bleach and water.
- ☐ 4. The diaphragm should be left in place for 2 hours after intercourse.

10. After being examined and fitted for a diaphragm, a 24-year-old client receives instructions about its use. Which client statement indicates a need for further teaching?

- ☐ 1. "I can continue to use the diaphragm for about 2 to 3 years if I keep it protected in the case."
- ☐ 2. "If I get pregnant, I will have to be refitted for another diaphragm after childbirth."
- ☐ 3. "Before inserting the diaphragm, I should coat the rim with contraceptive jelly."
- ☐ 4. "If I gain or lose 20 lb (9 kg), I can still use the same diaphragm."

11. A 22-year-old client tells the nurse that she and her husband are trying to conceive a baby. When teaching the client about reducing the incidence of neural tube defects, the nurse would emphasize the need for increasing the intake of which foods? Select all that apply.

- ☐ 1. leafy green vegetables
- ☐ 2. strawberries
- ☐ 3. beans
- ☐ 4. milk
- ☐ 5. sunflower seeds
- ☐ 6. lentils

12. A couple is inquiring about vasectomy as a permanent method of contraception. Which teaching statement would the nurse include in the teaching plan?

- ☐ 1. "Another method of contraception is needed until the sperm count is 0."

- ☐ 2. "Vasectomy is easily reversed if children are desired in the future."
- ☐ 3. "Vasectomy is contraindicated in males with prior history of cardiac disease."
- ☐ 4. "Vasectomy requires only a yearly follow-up once the procedure is completed."

13. A 39-year-old multigravid client asks the nurse for information about female sterilization with a tubal ligation. Which client statement indicates effective teaching?

- ☐ 1. "My fallopian tubes will be tied off through a small abdominal incision."
- ☐ 2. "Reversal of a tubal ligation is easily done, with a pregnancy success rate of 80%."
- ☐ 3. "After this procedure, I must abstain from intercourse for at least 3 weeks."
- ☐ 4. "Both of my ovaries will be removed during the tubal ligation procedure."

14. A 23-year-old nulliparous client visiting the clinic for a routine examination tells the nurse that she desires to use the basal body temperature method for family planning. What instructions should the nurse give the client?

- ☐ 1. Check the cervical mucus to see if it is thick and sparse.
- ☐ 2. Take her temperature at the same time every morning before getting out of bed.
- ☐ 3. Document ovulation when her temperature decreases at least 1°F (0.56°C).
- ☐ 4. Avoid coitus for 10 days after a slight rise in temperature.

15. A couple visiting the infertility clinic for the first time states that they have been trying to conceive for the past 2 years without success. After a history and physical examination of both partners, what would be the **most** appropriate outcome for the couple to accomplish by the end of this visit?

- ☐ 1. Choose an appropriate infertility treatment method.
- ☐ 2. Acknowledge that only 50% of infertile couples achieve a pregnancy.
- ☐ 3. Discuss alternative methods of having a family, such as adoption.

- ☐ 4. Describe each of the potential causes and possible treatment modalities.

16. A client is scheduled to have in vitro fertilization (IVF) as an infertility treatment. Which client statement about IVF indicates that the client understands this procedure?

- ☐ 1. "IVF requires supplemental estrogen to enhance the implantation process."
- ☐ 2. "The pregnancy rate with IVF is higher than that with gamete intrafallopian transfer."
- ☐ 3. "IVF involves bypassing the blocked or absent fallopian tubes."
- ☐ 4. "Both ova and sperm are instilled into the open end of a fallopian tube."

17. A 20-year-old primigravid client tells the nurse that her mother had a friend who died from hemorrhage about 10 years ago during a vaginal birth. Which response would be **most** helpful?

- ☐ 1. "Today's modern technology has resulted in a low maternal mortality rate."
- ☐ 2. "Do not concern yourself with things that happened in the past."
- ☐ 3. "In North America, mothers seldom die in childbirth."
- ☐ 4. "What is it that concerns you about pregnancy, labor, and birth?"

18. A 19-year-old nulligravid client visiting the clinic for a routine examination asks the nurse about cervical mucus changes that occur during the menstrual cycle. Which information would the nurse expect to include in the client's teaching plan?

- ☐ 1. About midway through the menstrual cycle, cervical mucus is thick and sticky.
- ☐ 2. During ovulation, the cervix remains dry without any mucus production.
- ☐ 3. As ovulation approaches, cervical mucus is abundant and clear.
- ☐ 4. Cervical mucus disappears immediately after ovulation, resuming with menses.

19. When instructing a client about the proper use of condoms for

pregnancy prevention, the nurse should include which instruction to ensure maximum effectiveness?

- ☐ 1. Place the condom over the erect penis before coitus.
- ☐ 2. Withdraw the condom after coitus when the penis is flaccid.
- ☐ 3. Ensure that the condom is pulled tightly over the tip of the penis before coitus.
- ☐ 4. Obtain a prescription for a condom with nonoxynol 9.

20. A multigravid client will be using medroxyprogesterone acetate as a family planning method. After the nurse instructs the client about this method, which client statement indicates effective teaching?

- ☐ 1. "This method of family planning requires monthly injections."
- ☐ 2. "I should have my first injection during my menstrual cycle."
- ☐ 3. "One possible adverse effect is absence of a menstrual period."
- ☐ 4. "This drug will be given by subcutaneous injections."

21. Which instruction should the nurse include in the teaching plan for a 30-year-old multiparous client who will be using an intrauterine device (IUD) for family planning?

- ☐ 1. Amenorrhea is a common adverse effect of IUDs.
- ☐ 2. The client needs to use additional protection for conception.
- ☐ 3. IUDs are more costly than other forms of contraception.
- ☐ 4. Severe cramping may occur when the IUD is inserted.

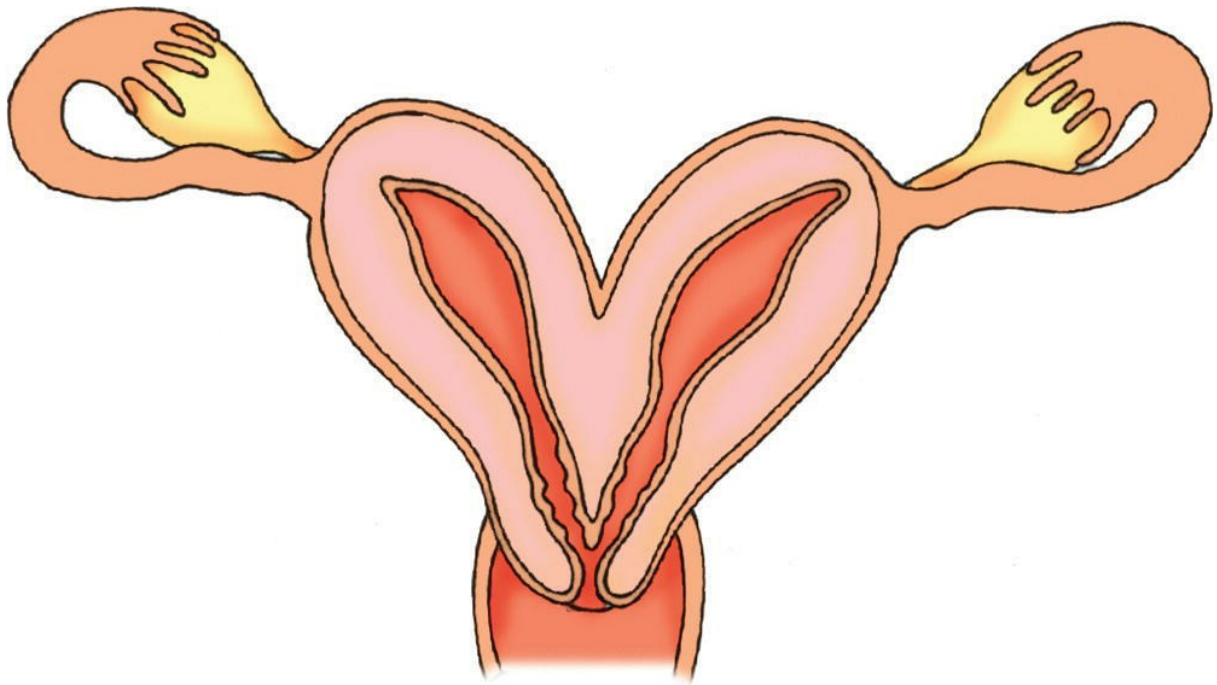

22. When developing a teaching plan for an 18-year-old client who asks about treatments for sexually transmitted infections, the nurse should explain that:

- ☐ 1. acyclovir can be used to cure herpes genitalis.
- ☐ 2. *Chlamydia trachomatis* infections are usually treated with penicillin.
- ☐ 3. ceftriaxone may be used to treat *Neisseria gonorrhoeae* infections.
- ☐ 4. metronidazole is used to treat condylomata acuminata.

23. A couple is visiting the clinic because they have been unable to conceive a baby after 3 years of frequent coitus. The nurse determines that the couple needs further instruction when they identify which factor as a cause of male infertility?

- ☐ 1. seminal fluid with an alkaline pH
- ☐ 2. frequent exposure to heat sources
- ☐ 3. abnormal hormonal stimulation
- ☐ 4. immunologic factors

24. At a preconception visit, a 24-year-old client is found to have malformation of the uterus. The nurse uses the figure below to explain which type of uterine malformation?

- ☐ 1. septate uterus
- ☐ 2. bicornuate uterus
- ☐ 3. double uterus
- ☐ 4. uterus didelphys

The Pregnant Client Receiving Prenatal Care

25. A primigravid client at 15 weeks' gestation has had an amniocentesis and has received teaching concerning signs and symptoms to report. Which statement indicates that the client needs further teaching?

- ☐ 1. "I need to call if I start to leak fluid from my vagina."
- ☐ 2. "If I start bleeding, I will need to call back."

- ☐ 3. "If my baby does not move, I need to call my health care provider."
- ☐ 4. "If I start running a fever, I should let the office know."

26. The nurse is caring for a client who is 12 weeks pregnant and speaks Spanish only. Which interventions should the nurse include in the plan of care at the client's initial visit? Select all that apply.

- ☐ 1. Provide brochures in the client's native language.
- ☐ 2. Refer the client to a high-risk clinic.
- ☐ 3. Discuss cultural differences, and emphasize the differences between cultures.
- ☐ 4. Arrange for an interpreter for her appointments.
- ☐ 5. Discuss contraception and options.
- ☐ 6. Review dietary intake, and discuss nutrition.

27. During a visit to the prenatal clinic, a pregnant client at 32 weeks' gestation has heartburn. The client needs further instruction when she says she must do what?

- ☐ 1. Avoid highly seasoned foods.
- ☐ 2. Avoid lying down right after eating.
- ☐ 3. Eat small, frequent meals.
- ☐ 4. Consume liquids only between meals.

28. The nurse is teaching a new prenatal client about her iron deficiency anemia during pregnancy. Which statement indicates that the client needs further instruction about her anemia?

- ☐ 1. "I will need to take iron supplements now."
- ☐ 2. "I may have anemia because my family is of Asian descent."
- ☐ 3. "I am considered anemic if my hemoglobin is below 11 g/dL (110 g/L)."
- ☐ 4. "The anemia increases the workload on my heart."

29. Following a positive pregnancy test, a client begins discussing the changes that will occur in the next several months with the nurse. The nurse should include which information about changes the client can anticipate in the first trimester?

- ☐ 1. differentiating the self from the fetus

- ☐ 2. enjoying the role of nurturer
- ☐ 3. preparing for the reality of parenthood
- ☐ 4. experiencing ambivalence about pregnancy

30. An antenatal primigravid client has just been informed that she is carrying twins. The plan of care includes educating the client concerning factors that put her at risk for problems during the pregnancy. The nurse realizes the client needs further instruction when she indicates carrying twins puts her at risk for which complication?

- ☐ 1. preterm labor
- ☐ 2. twin-to-twin transfusion
- ☐ 3. anemia
- ☐ 4. group B streptococcus

31. A 30-year-old multigravid client has missed three periods and now visits the prenatal clinic because she assumes she is pregnant. She is experiencing enlargement of her abdomen, a positive pregnancy test, and changes in the pigmentation on her face and abdomen. These assessment findings reflect this woman is experiencing a cluster of which signs of pregnancy?

- ☐ 1. positive
- ☐ 2. probable
- ☐ 3. presumptive
- ☐ 4. diagnostic

32. When preparing a 20-year-old client for a serum pregnancy test, what information should the nurse tell the client?

- ☐ 1. The test has a high degree of accuracy within 1 week after ovulation.
- ☐ 2. The test is identical in nature to an over-the-counter home pregnancy test.
- ☐ 3. A positive result is considered a presumptive sign of pregnancy.
- ☐ 4. A urine sample is needed to obtain quicker results.

33. After instructing a female client about the radioimmunoassay pregnancy test, the nurse determines that the client understands the instructions when the client states that which hormone is evaluated by this

test?

- ☐ 1. prolactin
- ☐ 2. follicle-stimulating hormone
- ☐ 3. luteinizing hormone
- ☐ 4. human chorionic gonadotropin (hCG)

34. Using Nägele's rule for a client whose last normal menstrual period began on May 10, the nurse determines that the client's estimated date of childbirth is what date?

- ☐ 1. January 13
- ☐ 2. January 17
- ☐ 3. February 13
- ☐ 4. February 17

35. After instructing a primigravid client about the functions of the placenta, the nurse determines that the client needs additional teaching when she says that which hormone is produced by the placenta?

- ☐ 1. estrogen
- ☐ 2. progesterone
- ☐ 3. human chorionic gonadotropin (hCG)
- ☐ 4. testosterone

36. The nurse assesses a woman at 24 weeks' gestation and is unable to find the fetal heartbeat. The fetal heartbeat was heard at the client's last visit 4 weeks ago. According to **priority**, the nurse should do the tasks in which order? All options must be used.

1. Call the healthcare provider (HCP).

2. Explain that the fetal heartbeat could not be found at this time.

3. Obtain different equipment and recheck.

4. Ask the client if the baby is or has been moving.

37. A primiparous client at 10 weeks' gestation questions the nurse about the need for an ultrasound. She states, "I feel fine, so why should I have the test?" The nurse should incorporate which statements as the underlying reason for performing the ultrasound now? Select all that apply.

- ☐ 1. "The test helps us view the gross anatomy of the fetus."
- ☐ 2. "We need to determine gestational age."
- ☐ 3. "The test will determine if the fetus is viable."
- ☐ 4. "We must determine fetal position."
- ☐ 5. "We must determine that there is a sufficient nutrient supply for the fetus."

38. A 20-year-old married client with a positive pregnancy test states, "Is it really true? I cannot believe I am going to have a baby!" Which response by the nurse would be **most** appropriate at this time?

- ☐ 1. "Would you like some booklets on the pregnancy experience?"
- ☐ 2. "Yes it is true. How does that make you feel?"
- ☐ 3. "You should be delighted that you are pregnant."
- ☐ 4. "What concerns you about this pregnancy?"

39. A newly diagnosed pregnant client tells the nurse, "If I am going to have all of these discomforts, I am not sure I want to be pregnant!" The nurse interprets the client's statement as an indication of which perception?

- ☐ 1. fear of pregnancy outcome
- ☐ 2. rejection of the pregnancy
- ☐ 3. normal ambivalence

- ☐ 4. inability to care for the newborn

40. A client, approximately 11 weeks pregnant, and her husband are seen in the antepartal clinic. The client's husband tells the nurse that he has been experiencing nausea and vomiting and fatigue along with his wife. The nurse interprets these findings as suggesting that the client's husband is experiencing which complication?

- ☐ 1. ptyalism
- ☐ 2. mittelschmerz
- ☐ 3. Couvade syndrome
- ☐ 4. pica

41. A primigravid client asks the nurse if she can continue to have a glass of wine with dinner during her pregnancy. Which statement would be the nurse's **best** response?

- ☐ 1. "The effects of alcohol on a fetus during pregnancy are unknown."
- ☐ 2. "You should limit your consumption to beer and wine."
- ☐ 3. "You should abstain from drinking alcoholic beverages."
- ☐ 4. "You may have 1 drink of 2 oz of alcohol per day."

42. Examination of a primigravid client having increased vaginal secretions since becoming pregnant reveals clear, highly acidic vaginal secretions. The client denies any perineal itching or burning. The nurse interprets these findings as a response related to which factor?

- ☐ 1. a decrease in vaginal glycogen stores
- ☐ 2. development of a sexually transmitted infection
- ☐ 3. prevention of expulsion of the cervical mucus plug
- ☐ 4. control of the growth of pathologic bacteria

43. When measuring the fundal height of a primigravid client at 20 weeks' gestation, the nurse will locate the fundal height at which point?

- ☐ 1. halfway between the client's symphysis pubis and umbilicus
- ☐ 2. at about the level of the client's umbilicus
- ☐ 3. between the client's umbilicus and xiphoid process
- ☐ 4. near the client's xiphoid process and compressing the diaphragm

44. A primigravida at 8 weeks' gestation tells the nurse that she wants an amniocentesis because there is a history of hemophilia A in her family. The nurse informs the client that she will need to wait until she is at 15 weeks' gestation for the amniocentesis. Which is the **most** appropriate rationale for the nurse's statement regarding amniocentesis at 15 weeks' gestation?

- ☐ 1. Fetal development needs to be complete before testing.
- ☐ 2. The volume of amniotic fluid needed for testing will be available by 15 weeks.
- ☐ 3. Cells indicating hemophilia A are not produced until 15 weeks' gestation.
- ☐ 4. Performing an amniocentesis prior to 15 weeks' gestation carries a greater infection rate.

45. After instructing a primigravid client about desired weight gain during pregnancy, the nurse determines that the teaching has been successful when the client makes which statement?

- ☐ 1. "A total weight gain of approximately 20 lb (9 kg) is recommended."
- ☐ 2. "A weight gain of 6.6 lb (3 kg) in the second and third trimesters is considered normal."
- ☐ 3. "A weight gain of about 12 lb (5.5 kg) every trimester is recommended."
- ☐ 4. "Although it varies, a gain of 25 to 35 lb (11.4 to 14.5 kg) is about average."

46. When developing a teaching plan for a client who is 8 weeks pregnant, what foods would the nurse suggest to meet the client's need for increased folic acid? Select all that apply.

- ☐ 1. spinach
- ☐ 2. bananas
- ☐ 3. seafood
- ☐ 4. yogurt
- ☐ 5. beans

47. The nurse instructs a primigravid client about the importance of sufficient vitamin A in her diet. The nurse knows that the instructions have

been effective when the client indicates that she should include which foods in her diet?

- ☐ 1. buttermilk and cheese
- ☐ 2. strawberries and broccoli
- ☐ 3. egg yolks and squash
- ☐ 4. oranges and tomatoes

48. The nurse is discussing dietary concerns with pregnant teens. Which of the following choices are convenient for teens yet nutritious for both the mother and fetus? Select all that apply.

- ☐ 1. milkshake or yogurt with fresh fruit or granola bar
- ☐ 2. chicken nuggets with tater tots
- ☐ 3. cheese pizza with spinach and mushroom topping
- ☐ 4. peanut butter with crackers and a juice drink
- ☐ 5. buttery light popcorn with diet cola
- ☐ 6. cheeseburger, pickle, and ketchup

49. An antenatal client is discussing her anemia with the nurse in the prenatal clinic. After a discussion about sources of iron to be incorporated into her daily meals, the nurse knows the client needs further instruction when she responds with which statement?

- ☐ 1. "I can meet two goals when I drink milk: lots of iron and meeting my calcium needs at the same time."
- ☐ 2. "Drinking coffee, tea, and sodas decreases the absorption of iron."
- ☐ 3. "I can increase the absorption of iron by drinking orange juice when I eat."
- ☐ 4. "Cream of wheat and molasses are excellent sources of iron."

50. The nurse instructs a primigravid client to increase her intake of foods high in magnesium because of its role in which process?

- ☐ 1. prevention of demineralization of the mother's bones
- ☐ 2. synthesis of proteins, nucleic acids, and fats
- ☐ 3. amino acid metabolism
- ☐ 4. synthesis of neural pathways in the fetus

51. A client is at 24 weeks' gestation. The nurse is reviewing the report of

laboratory tests as noted below.

The nurse should report which results to the health care provider (HCP)?

Laboratory Results	
Test	Result
Blood type	A-positive
Blood glucose	90 mg/dL (5 mmol/L)
VDRL	Positive
Rubella titer	Immune

- ☐ 1. blood type
- ☐ 2. VDRL
- ☐ 3. blood glucose
- ☐ 4. rubella titer

52. The nurse is reviewing a pregnant client's immunization record. Which immunizations are contraindicated during pregnancy and are not updated at this time? Select all that apply.

- ☐ 1. tetanus
- ☐ 2. rubella
- ☐ 3. mumps
- ☐ 4. chickenpox
- ☐ 5. live attenuated influenza vaccine (LAIV)
- ☐ 6. hepatitis B

53. A 34-year-old multiparous client at 16 weeks' gestation who received regular prenatal care for all of her previous pregnancies tells the nurse that she has already felt the baby move. How does the nurse interpret this finding?

- ☐ 1. the possibility that the client is carrying twins

- ☐ 2. unusual because most multiparous clients do not experience quickening until 30 weeks' gestation
- ☐ 3. evidence that the client's estimated date of childbirth is probably off by a few weeks
- ☐ 4. normal because multiparous clients can experience quickening between 14 and 20 weeks' gestation

54. A 17-year-old gravid client presents for her regularly scheduled 26-week prenatal visit. She appears disheveled, is wearing ill-fitting clothes, and does not make eye contact with the nurse. Which items should the nurse discuss with the client? Select all that apply.

- ☐ 1. intimate partner violence
- ☐ 2. substance abuse
- ☐ 3. depression
- ☐ 4. blood glucose screening
- ☐ 5. HCG (human chorionic gonadotropin) levels

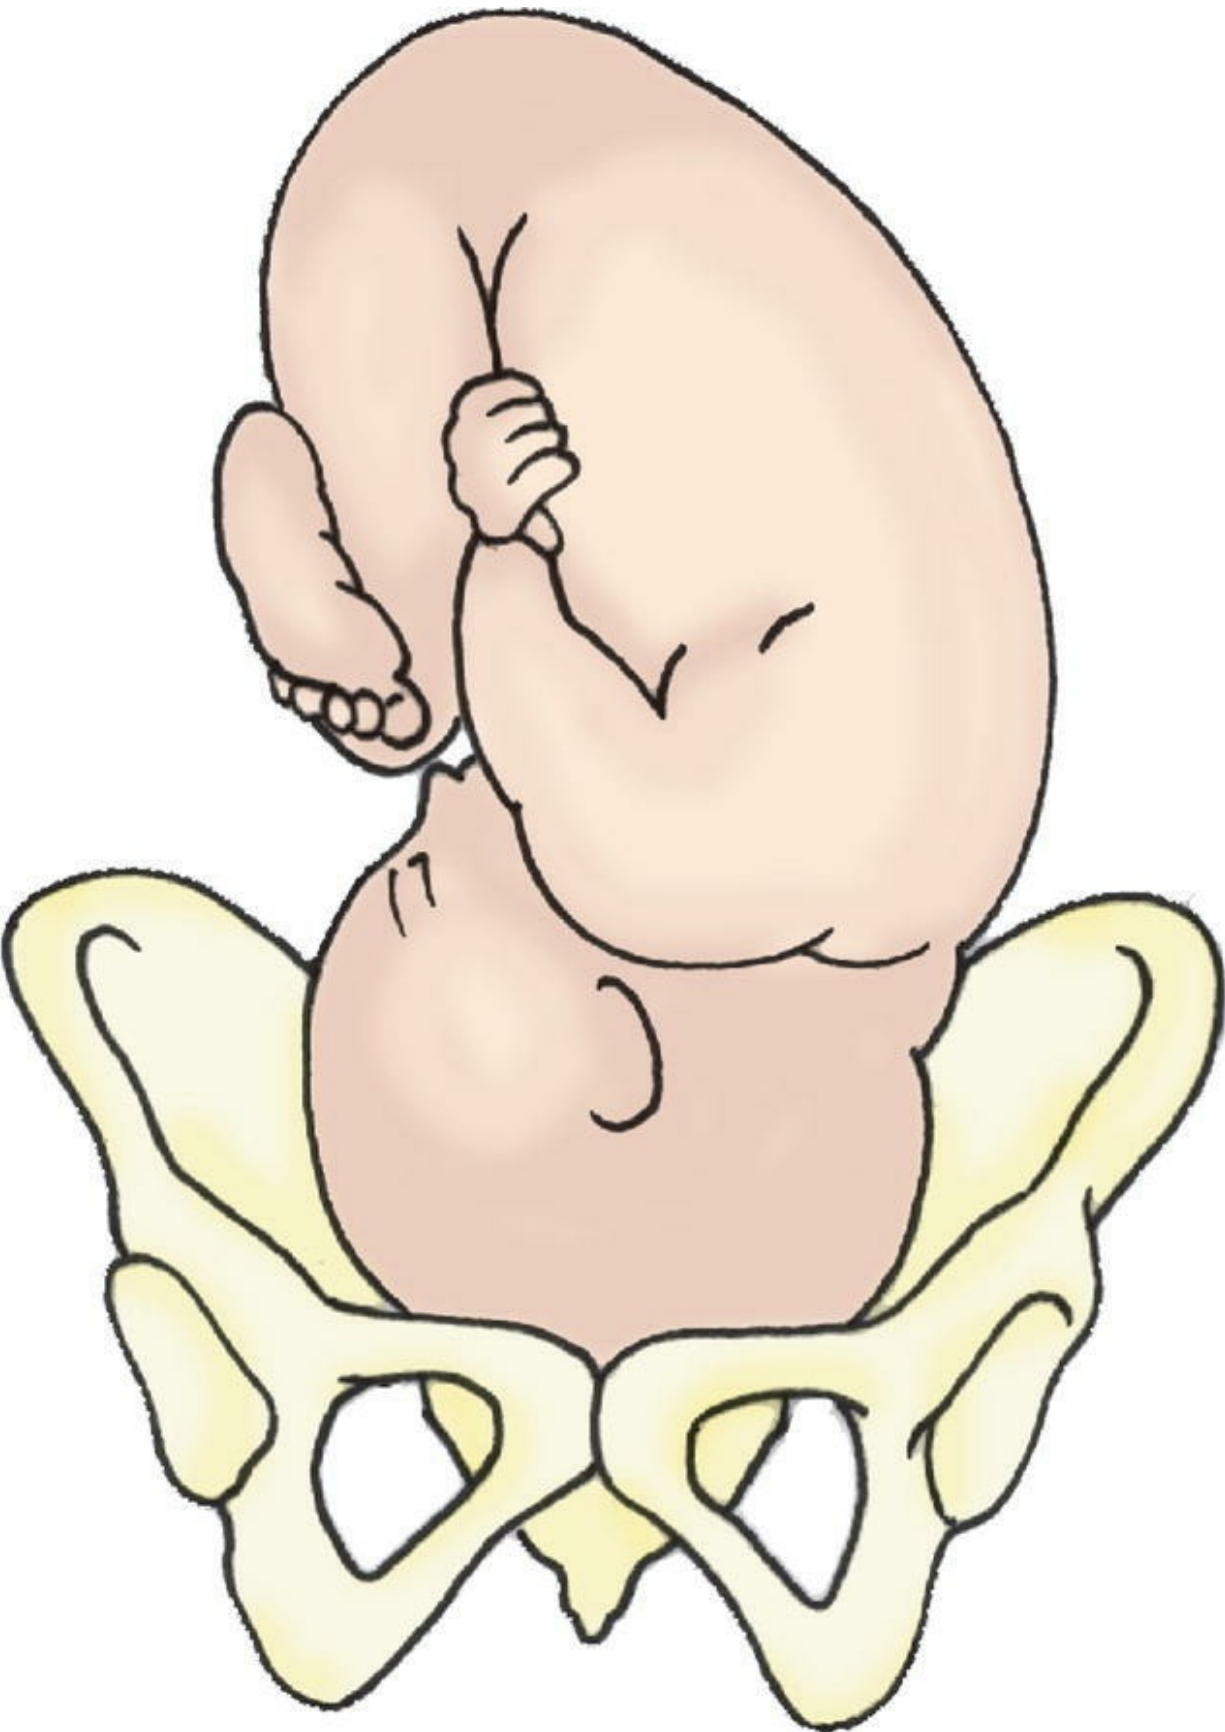

55. When performing Leopold's maneuvers, which action would the nurse ask the client to perform to ensure optimal comfort and accuracy?

- ☐ 1. breathe deeply for 1 minute
- ☐ 2. empty her bladder
- ☐ 3. drink a full glass of water
- ☐ 4. lie on her left side

56. The nurse performed Leopold's maneuvers and determined that the fetal position is ROA. Identify the area where the nurse would place the Doppler to **most** easily hear fetal heart sounds.

57. The nurse is assessing fetal position for a 32-year-old client in her 8th month of pregnancy. As shown below, the fetus is in which position?

- ☐ 1. left occipital transverse
- ☐ 2. left occipital anterior
- ☐ 3. right occipital transverse
- ☐ 4. right occipital anterior

58. Which statement by the nurse would be **most** appropriate when responding to a primigravid client who asks, “What should I do about this brown discoloration across my nose and cheeks?”

- ☐ 1. “This usually disappears after childbirth.”
- ☐ 2. “It is a sign of skin melanoma.”
- ☐ 3. “The discoloration is due to dilated capillaries.”
- ☐ 4. “It will fade if you use a prescribed cream.”

59. A 36-year-old primigravid client at 22 weeks’ gestation without any complications to date is being seen in the clinic for a routine visit. The nurse should assess the client’s fundal height to:

- ☐ 1. determine the level of uterine activity.
- ☐ 2. identify the need for increased weight gain.
- ☐ 3. assess the fetal position.
- ☐ 4. estimate the fetal growth.

60. After the nurse reviews the primary health care provider’s (HCP’s) explanation of amniocentesis with a multigravid client, which complication, if stated by the client, indicates that she needs more teaching about the procedure?

- ☐ 1. risk of infection
- ☐ 2. possible miscarriage
- ☐ 3. risk of club foot
- ☐ 4. fetal organ malformations

61. A primigravid client at 28 weeks’ gestation tells the nurse that she and her husband wish to drive to visit relatives who live several hours away. Which recommendation by the nurse would be **best**?

- ☐ 1. “Try to avoid traveling anywhere in the car during your third trimester.”

- ☐ 2. “Limit the time you spend in the car to a maximum of 4 to 5 hours.”
- ☐ 3. “Taking the trip is okay if you stop every 1 to 2 hours and walk.”
- ☐ 4. “Avoid wearing your seat belt in the car to prevent injury to the fetus.”

62. The nurse is teaching a woman who is 18 weeks pregnant about seat belt safety. Identify the area that indicates that the client understands where the lap portion of the seat belt should be placed.

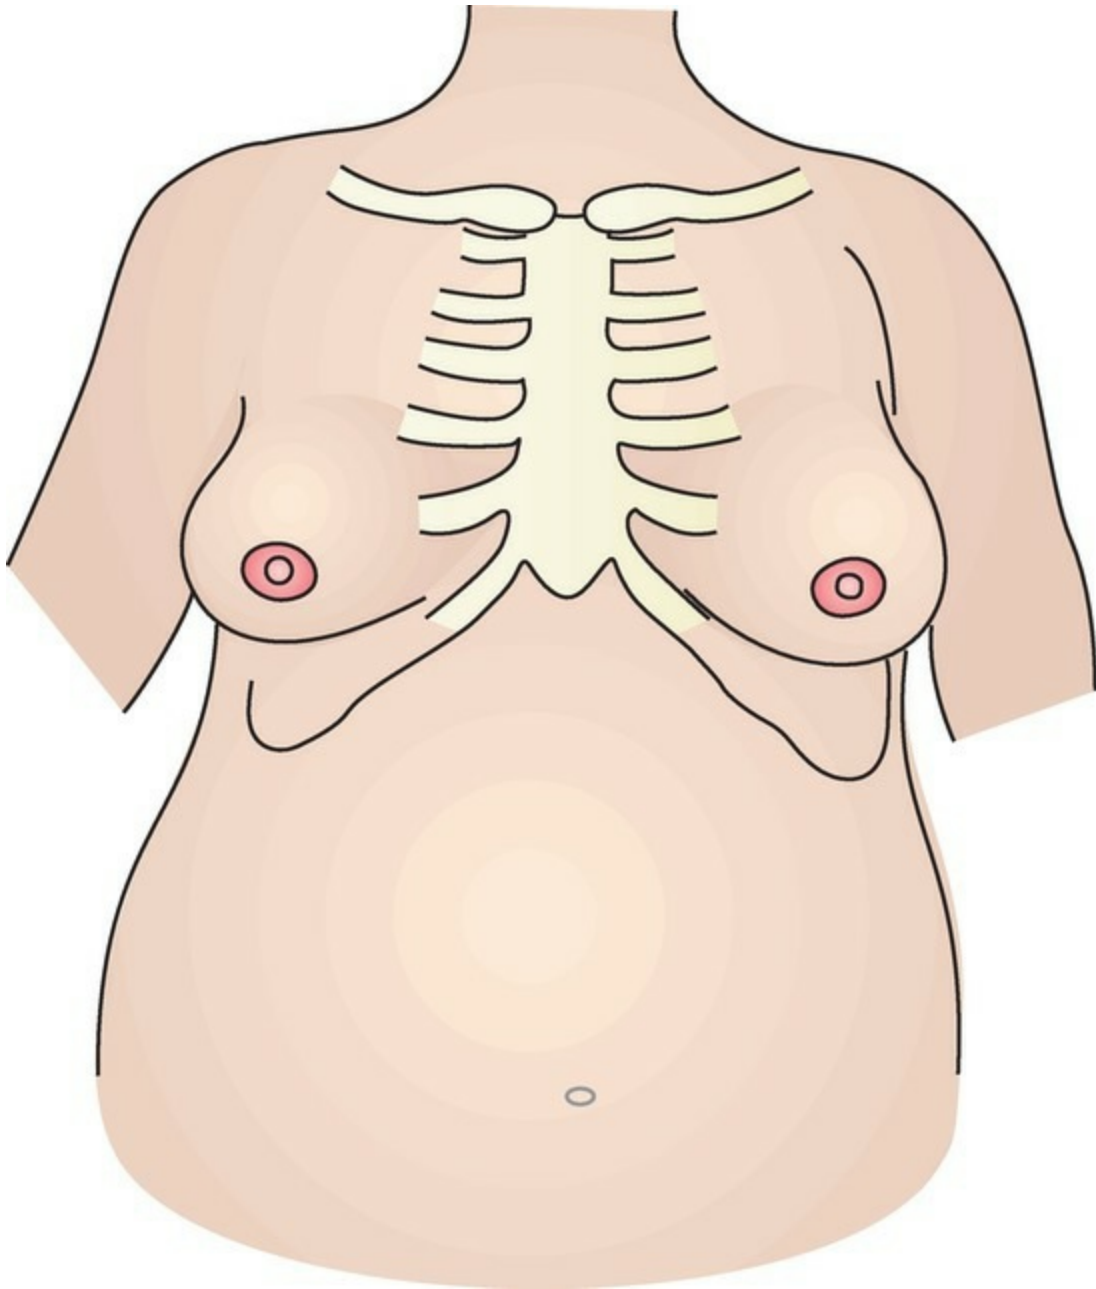

63. Which recommendation would be **most** helpful to suggest to a

primigravid client at 37 weeks' gestation who has leg cramps?

- ☐ 1. Change positions frequently throughout the day.
- ☐ 2. Alternately flex and extend the legs.
- ☐ 3. Straighten the knee and flex the toes toward the chin.
- ☐ 4. Lie prone in bed with the legs elevated.

64. A nurse eating lunch at a restaurant sees a pregnant woman showing signs of airway obstruction. When the nurse asks the woman if she needs help, the woman nods her head yes. Indicate the area where the nurse's fist should be placed to effectively administer thrusts to clear the foreign body from the airway.

65. When performing Leopold's maneuvers on a primigravid client at 22 weeks' gestation, the nurse performs the first maneuver to accomplish which action?

- ☐ 1. Locate the fetal back and spine.
- ☐ 2. Determine what is in the fundus.
- ☐ 3. Determine whether the fetal head is at the pelvic inlet.
- ☐ 4. Identify the degree of fetal descent and flexion.

66. A primigravid adolescent client at approximately 15 weeks' gestation is visiting the prenatal clinic to undergo maternal quad screening. What information should the nurse include in the teaching plan for this client?

- ☐ 1. Ultrasonography usually accompanies maternal quad screen testing.
- ☐ 2. Results are usually very accurate until 20 weeks' gestation.
- ☐ 3. A clean-catch midstream urine specimen is needed.
- ☐ 4. Increased levels of alpha fetoprotein are associated with neural tube defects.

67. Which statement **best** identifies the rationale for why the nurse reinforces the need for continued prenatal care throughout the pregnancy with an adolescent primigravid client?

- ☐ 1. Pregnant adolescents are at high risk for pregnancy-induced hypertension.
- ☐ 2. Gestational diabetes during pregnancy commonly develops in adolescents.
- ☐ 3. Adolescents need additional instruction related to common discomforts.
- ☐ 4. The father of the baby is rarely involved in the pregnancy.

68. Which information would be included in the teaching plan about pregnancy-related breast changes for a primigravid client?

- ☐ 1. Growth of the milk ducts is greatest during the first 8 weeks of gestation.
- ☐ 2. Enlargement of the breasts indicates adequate levels of progesterone.
- ☐ 3. Colostrum is usually secreted by about the 16th week of gestation.
- ☐ 4. Darkening of the areola occurs during the last month of pregnancy.

69. A primigravid client at 32 weeks' gestation is enrolled in a breast-feeding class. Which statements indicate that the client understands the breast-feeding education? Select all that apply.

- ☐ 1. "My milk supply will be adequate since I have increased a whole bra size during pregnancy."
- ☐ 2. "I can hold my baby several different ways during feedings."
- ☐ 3. "If my infant latches on properly, I will not develop mastitis."

- ☐ 4. “If I breast-feed, my uterus will return to prepregnancy size more quickly.”
- ☐ 5. “I need to feed my baby when I see feeding cues and not wait until she is crying.”

70. When planning a class for primigravid clients about the common physiologic changes of pregnancy, which information should the nurse include in the teaching plan?

- ☐ 1. The temperature decreases slightly early in pregnancy.
- ☐ 2. Cardiac output increases by 25% to 50% during pregnancy.
- ☐ 3. The circulating fibrinogen level decreases as much as 50% during pregnancy.
- ☐ 4. The anterior pituitary gland secretes oxytocin late in pregnancy.

71. When teaching a primigravid client at 24 weeks’ gestation about the diagnostic tests to determine fetal well-being, which information should the nurse include?

- ☐ 1. A fetal biophysical profile involves assessments of breathing movements, body movements, tone, amniotic fluid volume, and fetal heart rate reactivity.
- ☐ 2. A reactive nonstress test is an ominous sign and requires further evaluation with fetal echocardiography.
- ☐ 3. Contraction stress testing, performed on most pregnant women, can be initiated as early as 16 weeks’ gestation.
- ☐ 4. Percutaneous umbilical blood sampling uses a needle inserted through the vagina to obtain a sample.

72. A client asks why she feels so much variability in fetal activity each day. The nurse explains that fetal movement is affected by which factors? Select all that apply.

- ☐ 1. fetal sleep
- ☐ 2. barometric pressure
- ☐ 3. blood glucose
- ☐ 4. time of day
- ☐ 5. cigarette smoking

73. When teaching a primigravid client how to do Kegel exercises, the nurse explains that the expected outcome of these exercises is to:

- ☐ 1. reduce risk of hemorrhoids.
- ☐ 2. alleviate lower back discomfort.
- ☐ 3. strengthen the perineal muscles.
- ☐ 4. strengthen the abdominal muscles.

74. During a routine clinic visit, a 25-year-old multigravid client who initiated prenatal care at 10 weeks' gestation and is now in her third trimester states, "I've been having strange dreams about the baby. Last week I dreamed he was covered with hair." The nurse should tell the mother:

- ☐ 1. "Dreams like the ones that you describe are very unusual. Please tell me more about them."
- ☐ 2. "Commonly when a mother has these dreams, she is trying to cope with becoming a parent."
- ☐ 3. "Dreams about the baby late in pregnancy usually mean that labor is about to begin soon."
- ☐ 4. "It is not uncommon to have dreams about the baby, particularly in the third trimester."

75. A primigravid client at 36 weeks' gestation tells the nurse that she has been experiencing insomnia for the past 2 weeks. Which suggestion would be **most** helpful?

- ☐ 1. Practice relaxation techniques before bedtime.
- ☐ 2. Drink a cup of hot chocolate before bedtime.
- ☐ 3. Drink a small glass of wine with dinner.
- ☐ 4. Exercise for 30 minutes just before bedtime.

76. Which client statement indicates a need for additional teaching about self-care during pregnancy?

- ☐ 1. "I should use nonskid pads when I take a shower or bath."
- ☐ 2. "I should avoid using soap on my nipples to prevent drying."
- ☐ 3. "I should sit in a hot tub for 20 minutes to relax after working."
- ☐ 4. "I should avoid douching even if my vaginal secretions increase."

The Pregnant Client in Birth Preparation Classes

77. The nurse is developing a teaching plan for a client entering the third trimester of her pregnancy. The nurse should include which information in the plan? Select all that apply.

- ☐ 1. differentiating the fetus from the self
- ☐ 2. ambivalence concerning pregnancy
- ☐ 3. experimenting with mothering roles
- ☐ 4. realignment of roles and tasks
- ☐ 5. trying various caregiver roles
- ☐ 6. concern about labor and birth

78. A new antenatal G6, T4, P0, A1, L4 client attends her first prenatal visit with her partner. The nurse is assessing this couple's psychological response to the pregnancy. Which finding requires the **most** immediate follow-up?

- ☐ 1. The couple is concerned with financial changes this pregnancy causes.
- ☐ 2. The couple expresses ambivalence about the current pregnancy.
- ☐ 3. The father of the baby states that the pregnancy has changed the mother's focus.
- ☐ 4. The father of the baby is irritated that the mother is not like she was before pregnancy.

79. When preparing a prenatal class about endocrine changes that normally occur during pregnancy, the nurse should include information about which subject?

- ☐ 1. Human placental lactogen maintains the corpus luteum.
- ☐ 2. Progesterone is responsible for hyperpigmentation and vascular skin changes.
- ☐ 3. Estrogen relaxes smooth muscle in the respiratory tract.
- ☐ 4. The thyroid enlarges with an increase in basal metabolic rate.

80. When developing a series of parent classes on fetal development, the nurse should include which feature as being developed by the end of the 3rd month (9 to 12 weeks)?

- ☐ 1. external genitalia

- ☐ 2. myelinization of nerves
- ☐ 3. brown fat stores
- ☐ 4. air ducts and alveoli

81. A primigravid client attending parenthood classes tells the nurse that there is a history of twins in her family. What should the nurse tell the client?

- ☐ 1. Monozygotic twins result from fertilization of one ovum.
- ☐ 2. Monozygotic twins occur by chance regardless of race or heredity.
- ☐ 3. Dizygotic twins are usually of the same sex.
- ☐ 4. Dizygotic twins occur more often in primigravid than in multigravid clients.

82. During a 2-hour birth preparation class focusing on the labor and birth process for primigravid clients, the nurse is describing the maneuvers that the fetus goes through during the labor process when the head is the presenting part. In which order do these maneuvers occur? All options must be used.

1. engagement

2. flexion

3. descent

4. internal rotation

83. A primigravid client in a preparation for parenting class asks how

much blood is lost during an uncomplicated vaginal birth. The nurse should tell the woman:

- ☐ 1. "The maximum blood loss considered within normal limits is 500 mL."
- ☐ 2. "The minimum blood loss considered within normal limits is 1,000 mL."
- ☐ 3. "Blood loss during childbirth is rarely estimated unless there is a hemorrhage."
- ☐ 4. "It would be very unusual if you lost more than 100 mL of blood during childbirth."

84. Which statement by a primigravid client about the amniotic fluid and sac indicates the need for further teaching?

- ☐ 1. "The amniotic fluid helps to dilate the cervix once labor begins."
- ☐ 2. "Fetal nutrients are provided by the amniotic fluid."
- ☐ 3. "Amniotic fluid provides a cushion against impact of the maternal abdomen."
- ☐ 4. "The fetus is kept at a stable temperature by the amniotic fluid and sac."

85. During a birth preparation class, a primigravid client at 36 weeks' gestation tells the nurse, "My lower back has really been bothering me lately." Which exercise would be **most** helpful?

- ☐ 1. pelvic rocking
- ☐ 2. deep breathing
- ☐ 3. tailor sitting
- ☐ 4. squatting

86. A client is experiencing pain during the **first** stage of labor. What should the nurse instruct the client to do to manage her pain? Select all that apply.

- ☐ 1. Walk in the hospital room.
- ☐ 2. Use slow chest breathing.
- ☐ 3. Request pain medication on a regular basis.
- ☐ 4. Lightly massage the abdomen.
- ☐ 5. Sip ice water.

87. During a preparation for parenting class, one of the participants asks the nurse, “How will I know if I am really in labor?” What should the nurse tell the participant about true labor contractions?

- ☐ 1. “Walking around helps to decrease true contractions.”
- ☐ 2. “True labor contractions may disappear with ambulation, rest, or sleep.”
- ☐ 3. “The duration and frequency of true labor contractions remain the same.”
- ☐ 4. “True labor contractions are felt first in the lower back, then the abdomen.”

88. After instructing participants in a birth education class about methods for coping with discomforts in the first stage of labor, the nurse determines that one of the pregnant clients needs further instruction when she says that she has been practicing which technique?

- ☐ 1. biofeedback
- ☐ 2. effleurage
- ☐ 3. guided imagery
- ☐ 4. pelvic tilt exercises

89. After a preparation for parenting class session, a pregnant client tells the nurse that she has had some yellow-gray frothy vaginal discharge and local itching. What is the **best** advice for the nurse to give the client?

- ☐ 1. Use an over-the-counter cream for yeast infections.
- ☐ 2. Schedule an appointment at the clinic for an examination.
- ☐ 3. Administer a vinegar douche under low pressure.
- ☐ 4. Prepare for preterm labor and birth.

90. The topic of physiologic changes that occur during pregnancy is to be included in a parenting class for primigravid clients who are in their first half of pregnancy. Which topic would be important for the nurse to include in the teaching plan?

- ☐ 1. decreased plasma volume
- ☐ 2. increased risk for urinary tract infections
- ☐ 3. increased peripheral vascular resistance

- ☐ 4. increased hemoglobin levels

The Pregnant Client with Risk Factors

91. A multigravid client at 32 weeks' gestation has experienced hemolytic disease of the newborn in a previous pregnancy. The nurse should prepare the client for frequent antibody titer evaluations obtained from which source?

- ☐ 1. placental blood
- ☐ 2. amniotic fluid
- ☐ 3. fetal blood
- ☐ 4. maternal blood

92. Which diagnostic test would be the **most** important for a 40-year-old primigravid client to have in the second trimester of her pregnancy?

- ☐ 1. beta strep screening
- ☐ 2. chorionic villus sampling
- ☐ 3. ultrasound testing
- ☐ 4. quad screen

93. The nurse is caring for a client who has a history of gastric bypass surgery and is now being seen for her first prenatal visit. Which interventions should be included in the plan of care? Select all that apply.

- ☐ 1. Take a prenatal vitamin with 400 mcg of folic acid.
- ☐ 2. Refer the client to a registered dietician.
- ☐ 3. Draw glucose levels at each prenatal visit.
- ☐ 4. Counsel her that she will most likely gain all of her weight back.
- ☐ 5. Check urine at each visit for protein and glucose.
- ☐ 6. Monitor with nonstress tests beginning at 20 weeks.

94. A client with a past medical history of ventricular septal defect repaired in infancy is seen at the prenatal clinic. She has dyspnea with exertion and is very tired. Her vital signs are oxygen saturation 98, pulse 80, respirations 20, blood pressure 116/72 mm Hg. She has +2 pedal edema and clear breath sounds. The nurse determines the client's symptoms indicate which cardiac functional classification?

- ☐ 1. class I

- ☐ 2. class II
- ☐ 3. class III
- ☐ 4. class IV

95. A primigravid client has completed her first prenatal visit and blood work. Her laboratory test for the hepatitis B surface antigen (HBsAg) is positive. The nurse can advise the client that the plan of care for this newborn will include which interventions? Select all that apply.

- ☐ 1. hepatitis B immune globulin at birth
- ☐ 2. series of three hepatitis B vaccinations per recommended schedule
- ☐ 3. hepatitis B screening when born
- ☐ 4. isolation of infant during hospitalization
- ☐ 5. universal precautions for mother and infant
- ☐ 6. contraindication for breast-feeding

96. A woman with asthma controlled through the consistent use of medication is now pregnant for the first time. Which client statement concerning asthma during pregnancy indicates the need for further instruction?

- ☐ 1. "I need to continue taking my asthma medication as prescribed."
- ☐ 2. "It is my goal to prevent or limit asthma attacks."
- ☐ 3. "During an asthma attack, oxygen needs to continue to be high for mother and fetus."
- ☐ 4. "Bronchodilators should be used only when necessary because of the risk they present to the fetus."

97. A woman at 22 weeks' gestation has right upper quadrant pain radiating to her back. She rates the pain as 9 on a scale of 1 to 10 and says that it has occurred 2 times in the last week for about 4 hours at a time. She does not associate the pain with food. Which nursing measure is the **highest priority** for this client?

- ☐ 1. Educate the client concerning changes occurring in the gallbladder as a result of pregnancy.
- ☐ 2. Refer the client to her health care provider (HCP) for evaluation and treatment of the pain.

- ☐ 3. Discuss nutritional strategies to decrease the possibility of heartburn.
- ☐ 4. Support the client's use of acetaminophen to relieve pain.

98. A client in the triage area who is at 19 weeks' gestation states that she has not felt her baby move in the past week, and no fetal heart tones are found. While evaluating this client, the nurse identifies her as being at the **highest** risk for developing which problem?

- ☐ 1. abruptio placentae
- ☐ 2. HELLP syndrome
- ☐ 3. disseminated intravascular coagulation
- ☐ 4. threatened abortion

99. The nurse performs a routine prenatal assessment on a woman at 35 weeks' gestation and finds vital signs: blood pressure 138/88 mm Hg, pulse 82/min, respirations 18/min, temperature 99.1°F (37.3°C). Which statement is **most** appropriate for the nurse to make at this time?

- ☐ 1. "Your pulse is low. Do you exercise a lot?"
- ☐ 2. "Your blood pressure is slightly high. I will check it again before you leave."
- ☐ 3. "You have a slight temperature. Do you feel hot?"
- ☐ 4. "Your vital signs are all normal. I will document them on your medical record."

100. A 40-year-old client at 8 weeks' gestation has a 3-year-old child with Down syndrome. The nurse is discussing amniocentesis and chorionic villus sampling as genetic screening methods for the expected baby. The nurse is confident that the teaching has been understood when the client makes which statement?

- ☐ 1. "Each test identifies a different part of the infant's genetic makeup."
- ☐ 2. "Chorionic villus sampling can be performed earlier in pregnancy."
- ☐ 3. "The test results take the same length of time to be completed."
- ☐ 4. "Amniocentesis is a more dangerous procedure for the fetus."

101. After conducting a presentation to a group of adolescent parents on the topic of adolescent pregnancy, the nurse determines that one of the parents needs further instruction when the parent says that adolescents are at

greater risk for which complication?

- ☐ 1. denial of the pregnancy
- ☐ 2. low-birth-weight infant
- ☐ 3. cephalopelvic disproportion
- ☐ 4. congenital anomalies

102. A dilatation and curettage (D&C) is scheduled for a primigravid client admitted to the hospital at 10 weeks' gestation with abdominal cramping, bright red vaginal spotting, and passage of some of the products of conception. The nurse should assess the client further for the expression of which feeling?

- ☐ 1. ambivalence
- ☐ 2. anxiety
- ☐ 3. fear
- ☐ 4. guilt

103. When providing care to the client who has undergone a dilatation and curettage (D&C) after a spontaneous abortion, the nurse administers hydroxyzine as prescribed. What is an expected outcome?

- ☐ 1. absence of nausea
- ☐ 2. minimized pain
- ☐ 3. decreased uterine cramping
- ☐ 4. improved uterine contractility

104. On entering the room of a client who has undergone a dilatation and curettage (D&C) for a spontaneous abortion, the nurse finds the client crying. Which comment by the nurse would be **most** appropriate?

- ☐ 1. "Are you having a great deal of uterine pain?"
- ☐ 2. "Commonly spontaneous abortion means a defective embryo."
- ☐ 3. "I am truly sorry you lost your baby."
- ☐ 4. "It is important that you do not try to get pregnant too soon."

105. Rho (D) immune globulin (RhoGAM) is prescribed for a client before she is discharged after a spontaneous abortion. The nurse instructs the client that this drug is used to prevent which condition?

- ☐ 1. development of a future Rh-positive fetus

- ☐ 2. an antibody response to Rh-negative blood
- ☐ 3. a future pregnancy resulting in abortion
- ☐ 4. development of Rh-positive antibodies

106. A multigravid client who stands for long periods while working in a factory visits the prenatal clinic at 35 weeks' gestation, stating, "The varicose veins in my legs have really been bothering me lately." Which instruction would be **most** helpful?

- ☐ 1. Perform slow contraction and relaxation of the feet and ankles twice daily.
- ☐ 2. Take frequent rest periods with the legs elevated above the hips.
- ☐ 3. Avoid support hose that reach above the leg varicosities.
- ☐ 4. Take a leave of absence from your job to avoid prolonged standing.

107. A primigravid client at 8 weeks' gestation tells the nurse that since having had sexual relations with a new partner 2 weeks ago, she has noticed flu-like symptoms, enlarged lymph nodes, and clusters of vesicles on her vagina. The nurse refers the client to a primary health care provider (HCP) because the nurse suspects which sexually transmitted infection?

- ☐ 1. gonorrhea
- ☐ 2. *Chlamydia trachomatis* infection
- ☐ 3. syphilis
- ☐ 4. herpes genitalis

108. While caring for a 24-year-old primigravid client scheduled for emergency surgery because of a probable ectopic pregnancy, the nurse should:

- ☐ 1. prepare to witness an informed consent for surgery.
- ☐ 2. assess the client for massive external bleeding.
- ☐ 3. explain that the fallopian tube can be salvaged.
- ☐ 4. monitor the client for uterine contractions.

Managing Care, Quality, and Safety for Childbearing Clients

109. The nurse is reviewing results for clients who are having antenatal

testing. The assessment data from which client warrants prompt notification of the health care provider (HCP) and a further plan of care?

- ☐ 1. primigravida who reports fetal movement 6 times in 2 hours
- ☐ 2. multigravida who had a positive oxytocin challenge test
- ☐ 3. primigravida whose infant has a biophysical profile of 9.
- ☐ 4. multigravida whose infant has a reactive nonstress test.

110. A client asks the nurse why taking folic acid is so important before and during pregnancy. The nurse should instruct the client that:

- ☐ 1. “Folic acid is important in preventing neural tube defects in newborns and preventing anemia in mothers.”
- ☐ 2. “Eating foods with moderate amounts of folic acid helps regulate blood glucose levels.”
- ☐ 3. “Folic acid consumption helps with the absorption of iron during pregnancy.”
- ☐ 4. “Folic acid is needed to promote blood clotting and collagen formation in the newborn.”

111. A nurse is assigned to the obstetrical triage area. When beginning the assignment, the nurse is given a report about four clients waiting to be seen. Place the clients in the order in which the nurse should see them. All options must be used.

1. a primigravid client at 10 weeks’ gestation stating she is not feeling well with nausea and vomiting, urinary frequency, and fatigue

2. a multiparous client at 32 weeks’ gestation asking for assistance with finding a new primary health care provider (HCP)

3. a single mother at 4 months postpartum fearful of shaking her baby when he cries

4. an antenatal client at 16 weeks’ gestation who has occasional sharp pain

on her left side radiating from her symphysis to her fundus

- 112.** The nurse is working in an ambulatory obstetrics setting. What are emphasized client safety procedures for this setting? Select all that apply.
- ☐ 1. handwashing or antiseptic use when entering and leaving a room
 - ☐ 2. use of two client identifiers when initiating contact with a client
 - ☐ 3. use same abbreviations as in the hospital setting
 - ☐ 4. conduct preprocedure verification asking for client name and procedure to be performed
 - ☐ 5. prevent infection by isolating anyone with nausea and vomiting

Answers, Rationales, and Test-Taking Strategies

*The answers and rationales for each question follow below, along with keys () to the client need (CN) and cognitive level (CL) for each question. In addition, you will also see a glossary icon () highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 12–23 and pages 35–36 in Part 1 of this book.*

The Preconception Client

1. 1. Levonorgestrel can reduce the chance of pregnancy if taken within 72 hours of unprotected intercourse, and then again 12 hours later. Waiting 4 days to take levonorgestrel reduces effectiveness. Males can purchase this

contraceptive as long as they are over 18 years of age. Levonorgestrel works by preventing ovulation or fertilization depending on where a client is in the menstrual cycle. Common side effects include nausea, breast tenderness, vertigo, and stomach pain.

CN: Physiological adaptation; CL: Evaluate

2. 3. Birth control plans are influenced primarily by whether the mother is breast- or bottle-feeding her infant. The maternal milk supply must be well established prior to the initiation of most hormonal birth control methods. Low-dose oral contraceptives would be the exception. Use of estrogen-/progesterone-based pills and progesterone-only pills are commonly initiated from 4 to 6 weeks postpartum because the milk supply is well established by this time. Prior experiences with birth control methods have an impact on the method chosen as do the preferences of the client's partner; however, they are not the most influential factors. Desire to have another child in 2 years would make some methods, such as an IUD, less attractive but would still be secondary to the choice to breast-feed.

CN: Pharmacological and parenteral therapies; CL: Analyze

3. 3. For a client with a typical menstrual cycle of 28 days, ovulation usually occurs on day 14, plus or minus 2 days, before the onset of the next menstrual cycle. Stated another way, the menstrual period begins about 2 weeks after ovulation has occurred. Ovulation does not usually occur during the menses component of the cycle when the uterine lining is being shed. In most women, the ovum survives for about 12 to 24 hours after ovulation, during which time conception is possible. The basal body temperature rises 0.5°F to 1.0°F (0.28°C to 0.56°C) when ovulation occurs. Although some women experience some pelvic discomfort during ovulation (mittelschmerz), severe or unusual pain is rare. After ovulation, the cervical mucus is thin and copious.

CN: Health promotion and maintenance; CL: Create

4. 1. The nurse should instruct the client to take a mild analgesic, such as ibuprofen, if menstrual pain or “cramps” are present. The client should also eat foods rich in iron and should continue moderate exercise during menstruation, which increases abdominal tone. Avoiding cold foods will not

decrease dysmenorrhea. Use of pads or tampons is a personal choice. There is no evidence that it is necessary to wait to use tampons.

CN: Health promotion and maintenance; CL: Apply

5. 1. Under ideal conditions, sperm can reach the ovum in 15 to 30 minutes. This is an important point to make with adolescents who may be sexually active. Many people believe that the time interval is much longer and that they can wait until after intercourse to take steps to prevent conception. Without protection, pregnancy and sexually transmitted diseases can occur. When using the abstinence or calendar method, the couple should abstain from intercourse on the days of the menstrual cycle when the woman is most likely to conceive. Using a 28-day cycle as an example, a couple should abstain from coitus 3 to 4 days before ovulation (days 10 through 14) and 3 to 4 days after ovulation (days 15 through 18). Sperm from a healthy male can remain viable for 24 to 72 hours in the female reproductive tract. If the female client ovulates after coitus, there is a possibility that fertilization can occur. Before fertilization, the ovum and sperm each contain 23 chromosomes. After fertilization, the conceptus contains 46 chromosomes unless there is a chromosomal abnormality.

CN: Health promotion and maintenance; CL: Evaluate

6. 3. The symptothermal method is a natural method of fertility management that depends on knowing when ovulation has occurred. Because regular menstrual cycles can vary by 1 to 2 days in either direction, the symptothermal method requires daily basal body temperature assessments plus close monitoring of cervical mucus changes. The method relies on abstinence during the period of ovulation, which occurs approximately 14 days before the beginning of the next cycle. Abstinence from coitus for 5 days after menses is unnecessary because it is unlikely that ovulation will occur during this time period (days 1 through 10). Typically, the failure rate for this method is between 10% and 20%. Although a condom may increase the effectiveness of this method, most clients who choose natural methods are not interested in chemical or barrier types of family planning.

CN: Health promotion and maintenance; CL: Create

7. 2. Before advising a client about oral contraceptives, the nurse needs to

assess the client for signs and symptoms of hypertension. Clients who have hypertension, thrombophlebitis, obesity, or a family history of cerebral or cardiovascular accident are poor candidates for oral contraceptives. In addition, women who smoke, are older than 40 years of age, or have a history of pulmonary disease should be advised to use a different method. Iron deficiency anemia, dysmenorrhea, and acne are not contraindications for the use of oral contraceptives. Iron deficiency anemia is a common disorder in young women. Oral contraceptives decrease the amount of menstrual flow and thus decrease the amount of iron lost through menses, thereby providing a beneficial effect when used by clients with anemia. Low-dose oral contraceptives to prevent ovulation may be effective in decreasing the severity of dysmenorrhea (painful menstruation). Dysmenorrhea is thought to be caused by the release of prostaglandins in response to tissue destruction during the ischemic phase of the menstrual cycle. Use of oral contraceptives commonly improves facial acne.

CN: Reduction of risk potential; CL: Analyze

8. 4. The nurse determines that the client needs further instruction when the client says that one of the adverse effects of oral contraceptive use is ovarian cancer. Some studies suggest that ovarian and endometrial cancers are reduced in women using oral contraceptives. Other adverse effects of oral contraceptives include weight gain, nausea, headache, breakthrough bleeding, and monilial infections. The most serious adverse effect is thrombophlebitis.

CN: Pharmacological and parenteral therapies; CL: Evaluate

9. 2. The teaching plan should include a caution that a diaphragm should not be used if the client develops acute cervicitis, possibly aggravated by contact with the rubber of the diaphragm. Some studies have also associated diaphragm use with increased incidence of urinary tract infections. Douching after use of a diaphragm and intercourse is not recommended because pregnancy could occur. The diaphragm should be inspected and washed with mild soap and water after each use. A diaphragm should be left in place for at least 6 hours but no longer than 24 hours after intercourse. More spermicidal jelly or cream should be used if intercourse is repeated during this period.

CN: Reduction of risk potential; CL: Create

10. 4. The client would need additional instructions when she says that she can still use the same diaphragm if she gains or loses 20 lb (9 kg). Gaining or losing more than 15 lb (6.8 kg) can change the pelvic and vaginal contours to such a degree that the diaphragm will no longer protect the client against pregnancy. The diaphragm can be used for 2 to 3 years if it is cared for and well protected in its case. The client should be refitted for another diaphragm after pregnancy and childbirth because weight changes and physiologic changes of pregnancy can alter the pelvic and vaginal contours, thus affecting the effectiveness of the diaphragm. The client should use a spermicidal jelly or cream before inserting the diaphragm.

CN: Reduction of risk potential; CL: Evaluate

11. 1,2,3,5,6. The pregnancy requirement for folic acid is 400 to 800 mcg/day. Major sources of folic acid include leafy green vegetables, strawberries and oranges, beans, particularly black and kidney beans, sunflower seeds, and lentils. Milk and fats contain no folic acid.

CN: Health promotion and maintenance; CL: Apply

12. 1. Another method of contraception is needed until all sperm has been cleared from the body. The number of ejaculates for this to occur varies with the individual, and laboratory analysis is required to determine when that has been accomplished. Vasectomy is considered a permanent sterilization procedure and requires microsurgery for anastomosis of the vas deferens to be completed. Studies have shown that there is no connection between cardiac disease in males and vasectomy. There is no need for follow-up after verification that there is no sperm in the system.

CN: Physiological adaptation; CL: Create

13. 1. Tubal ligation, a female sterilization procedure, involves ligation (tying off) or cauterization of the fallopian tubes through a small abdominal incision (laparotomy). Reversal of a tubal ligation is not easily done, and the pregnancy success rate after reversal is about 30%. After a tubal ligation, the client may engage in intercourse 2 to 3 days after the procedure. The ovaries are not generally removed during a tubal ligation. An oophorectomy involves removal of one or both ovaries.

CN: Health promotion and maintenance; CL: Evaluate

14. 2. The basal body temperature method requires that the client take her temperature each morning before getting out of bed, preferably at the same time each day before eating or any other activity. Just before the day of ovulation, the temperature falls by 0.5°F (0.28°C). At the time of ovulation, the temperature rises 0.4°F to 0.8°F (0.22°C to 0.44°C) because of increased progesterone secretion in response to the luteinizing hormone. The temperature remains higher for the rest of the menstrual cycle. The client should keep a diary of about 6 months of menstrual cycles to calculate “safe” days. There is no mucus for the first 3 or 4 days after menses, and then thick, sticky mucus begins to appear. As estrogen increases, the mucus changes to clear, slippery, and stretchy. This condition, termed spinnbarkeit, is present during ovulation. After ovulation, the mucus decreases in amount and becomes thick and sticky again until menses. Because the ovum typically survives about 24 hours and sperm can survive up to 72 hours, couples must avoid coitus when the cervical mucus is copious and for about 3 to 4 days before and after ovulation to avoid a pregnancy.

CN: Health promotion and maintenance; CL: Apply

15. 4. By the end of the first visit, the couple should be able to identify potential causes and treatment modalities for infertility. If their evaluation shows that a treatment or procedure may help them to conceive, the couple must then decide how to proceed, considering all of the various treatments before selecting one. Treatments can be difficult, painful, or risky. The first visit is not the appropriate time to decide on a treatment plan because the couple needs time to adjust to the diagnosis of infertility, a crisis for most couples. Although the couple may be in a hurry for definitive therapy, a thorough assessment of both partners is necessary before a treatment plan can be initiated. The success rate for achieving a pregnancy depends on both the cause and the effectiveness of the treatment, and in some cases, it may be only as high as 30%. The couple may desire information about alternatives to treatment, but insufficient data are available to suggest that a specific treatment modality may not be successful. Suggesting that the couple consider adoption at this time may inappropriately imply that the couple has no other choice. If a specific therapy may result in a pregnancy, the couple

should have time to consider their options. After a thorough evaluation, adoption may be considered by the couple as an alternative to the costly, time-consuming, and sometimes painful treatments for infertility.

CN: Health promotion and maintenance; CL: Analyze

16. 3. The client's understanding of the procedure is demonstrated by the statement describing IVF as a technique that involves bypassing the blocked or absent fallopian tubes. The primary **health care provider (HCP)** removes the ova by laparoscope- or ultrasound-guided transvaginal retrieval and mixes them with prepared sperm from the woman's partner or a donor. Two days later, up to four embryos are returned to the uterus to increase the likelihood of a successful pregnancy. Supplemental progesterone, not estrogen, is given to enhance the implantation process. Gamete intrafallopian transfer (GIFT) and tubal embryo transfer have a higher pregnancy rate than does IVF. However, these procedures cannot be used for clients who have blocked or absent fallopian tubes because the fertilized ova are placed into the fallopian tubes, subsequently entering the uterus naturally for implantation. In IVF, fertilization of the ova by the sperm occurs outside the client's body. In GIFT, both ova and sperm are implanted into the fallopian tubes and allowed to fertilize within the woman's body.

CN: Reduction of risk potential; CL: Evaluate

17. 4. The client is verbalizing concerns about death during childbirth, thus providing the nurse with an opportunity to gather additional data. Asking the client about these concerns would be most helpful to determine the client's knowledge base and to provide the nurse with the opportunity to answer any questions and clarify any misconceptions. Although the maternal mortality rate is low in the United States and Canada, maternal deaths do occur, even with modern technology. Leading causes of maternal mortality in the United States and Canada include embolism, pregnancy-induced hypertension, hemorrhage, ectopic pregnancy, and infection. Telling the client not to concern herself about what has happened in the past is not useful. It only serves to discount the client's concerns and block further therapeutic communication. Also, postponing or ignoring the client's need for a discussion about complications of pregnancy may further increase the client's anxiety.

CN: Health promotion and maintenance; CL: Apply

18. 3. As ovulation approaches, cervical mucus is abundant and clear, resembling raw egg white. Ovulation generally occurs 14 days (± 2 days) before the beginning of menses. During the luteal phase of the cycle, which occurs after ovulation, the cervical mucus is thick and sticky, making it difficult for sperm to pass. Changes in the cervical mucus are related to the influences of estrogen and progesterone. Cervical mucus is always present.

CN: Health promotion and maintenance; CL: Create

19. 1. To ensure maximum effectiveness, the condom should always be placed over the erect penis before coitus. Some couples find condom use objectionable because foreplay may have to be interrupted to apply the condom. The penis, covered by the condom, should be withdrawn before the penis becomes flaccid. Otherwise semen may escape from the condom, providing an opportunity for possible fertilization. Rather than having the condom pulled tightly over the penis before coitus, space should be left at the tip of the penis to allow the condom to hold the sperm. The client does not need a prescription for a condom with nonoxynol 9 because these are sold over the counter.

CN: Reduction of risk potential; CL: Apply

20. 3. With medroxyprogesterone acetate, irregular menstrual cycles and amenorrhea are common adverse effects. Other adverse effects include weight gain, breakthrough bleeding, headaches, and depression. This method requires deep intramuscular injections every 3 months. The first injection should occur within 5 days after menses.

CN: Reduction of risk potential; CL: Evaluate

21. 4. Severe cramping and pain may occur as the device is passed through the internal cervical os. The insertion of the device is generally done when the client is having her menses because it is unlikely that she is pregnant at that time. Common adverse effects of IUDs are heavy menstrual bleeding and subsequent anemia, not amenorrhea. Uterine infection or ectopic pregnancy may occur. The IUD has an effectiveness rate of 98%. Therefore, additional protection is not necessary to prevent pregnancy. IUDs generally are less

costly than other forms of contraception because they do not require additional expense. Only one insertion is necessary, in comparison to daily doses of oral contraceptives or the need for spermicides in conjunction with diaphragm use.

CN: Reduction of risk potential; CL: Apply

22. 3. Ceftriaxone may be used to treat *N. gonorrhoeae* infections and is commonly combined with doxycycline. Both the client and her partner should be treated if gonorrhea is present. Acyclovir can be used to treat herpes genitalis; however, the drug does not cure the disease. *C. trachomatis* infections are usually treated with antibiotics such as doxycycline or azithromycin. Metronidazole is used to treat trichomoniasis vaginitis, not condylomata acuminata (genital warts).

CN: Pharmacological and parenteral therapies; CL: Create

23. 1. The couple needs further instruction when they identify that one cause of male infertility is decreased sperm count due to seminal fluid that has an alkaline pH. A slightly alkaline pH is necessary to protect the sperm from the acidic secretions of the vagina and is a normal finding. An alkaline pH is not associated with decreased sperm count. However, seminal fluid that is abnormal in amount, consistency, or chemical composition suggests obstruction, inflammation, or infection, which can decrease sperm production. The typical number of sperm produced during ejaculation is 400 million. Frequent exposure to heat sources, such as saunas and hot tubs, can decrease sperm production, as can abnormal hormonal stimulation. Immunologic factors produced by the man against his own sperm (autoantibodies) or by the woman can cause the sperm to clump or be unable to penetrate the ovum, thus contributing to infertility.

CN: Health promotion and maintenance; CL: Evaluate

24. 2. A bicornuate uterus has a “Y” shape and appears to be a double uterus but in fact has only one cervix. A septate uterus contains a septum that extends from the fundus to the cervix, thus dividing the uterus into two separate compartments. A double uterus has two uteri, each of which has a cervix. A uterus didelphys occurs when both uteri of a double uterus are fully formed.

 CN: Physiological adaptation; CL: Apply

The Pregnant Client Receiving Prenatal Care

25. 3. At 15 weeks' gestation, a primipara will not feel the baby moving. Quickening typically occurs between 18 and 20 weeks' gestation for a primipara and between 16 and 18 weeks' gestation for a multipara. Leaking fluid from the vagina should not occur until labor begins and may indicate a rupture of the membranes. Bleeding and a fever are complications that warrant further evaluation and should be reported at any time during the pregnancy.

 CN: Health promotion and maintenance; CL: Evaluate

26. 1,4,6. Providing culturally sensitive care includes providing printed material in the client's native language. There is nothing to indicate that this client has a high-risk pregnancy. Discussing cultural differences is not a priority or important at the first visit. Clients need to have an interpreter for each prenatal visit to translate and interpret questions. Contraceptive options are not a priority for the first prenatal visit. Reviewing dietary intake and discussing nutrition are an important component of early prenatal care.

 CN: Health promotion and maintenance; CL: Create

27. 4. Consuming most liquids between meals rather than at the same time as eating is an excellent strategy to deter nausea and vomiting in pregnancy but does not relieve heartburn. During the third trimester, progesterone causes relaxation of the sphincter, and the pressure of the fetus against the stomach increases the potential of heartburn. Avoiding highly seasoned foods, remaining in an upright position after eating, and eating small, frequent meals are strategies to prevent heartburn.

 CN: Physiological adaptation; CL: Evaluate

28. 2. Iron deficiency anemia is caused by insufficient iron stores in the body, poor iron content in the diet of the pregnant woman, or both. Other thalassemias and sickle cell anemia, rather than iron deficiency anemia, can be associated with ethnicity but occur primarily in clients of African or Mediterranean origin. Because red blood cells increase by about 50% during

pregnancy, many clients will need to take supplemental iron to avoid iron - deficiency anemia. A pregnant client is considered anemic when the hemoglobin is below 11 mg/dL (110 g/dL). In most types of anemia, the heart must pump more often and harder to deliver oxygen to cells.

CN: Reduction of risk potential; CL: Evaluate

29. 4. Many women in their first trimester feel ambivalent about being pregnant because of the significant life changes that occur for most women who have a child. Ambivalence can be expressed as a list of positive and negative consequences of having a child, consideration of financial and social implications, and possible career changes. During the second trimester, the infant becomes a separate individual to the mother. The mother will begin to enjoy the role of nurturer postpartum. During the third trimester, the mother begins to prepare for parenthood and all of the tasks that parenthood includes.

CN: Health promotion and maintenance; CL: Apply

30. 4. Group B streptococcus is a risk factor for all pregnant women and is not limited to those carrying twins. The multiple gestation client is at risk for preterm labor because uterine distention, a major factor initiating preterm labor, is more likely with a twin gestation. The normal uterus is only able to distend to a certain point, and when that point is reached, labor may be initiated. Twin-to-twin transfusion drains blood from one twin to the second and is a problem that may occur with multiple gestations. The donor twin may become growth restricted and can have oligohydramnios, while the recipient twin may become polycythemic with polyhydramnios and develop heart failure. Anemia is a common problem with multiple gestation clients. The mother is commonly unable to consume enough protein, calcium, and iron to supply her needs and those of the fetuses. A maternal hemoglobin level below 11 mg/dL (110 g/L) is considered anemic.

CN: Physiological adaptation; CL: Evaluate

31. 2. The plan of care should reflect that this woman is experiencing probable signs of pregnancy. She may be pregnant, but the signs and symptoms may have another etiology. An enlarging abdomen and a positive pregnancy test may also be caused by tumors, hydatidiform mole, or other disease processes as well as pregnancy. Changes in the pigmentation of the

face may also be caused by oral contraceptive use. Positive signs of pregnancy are considered diagnostic and include evident fetal heartbeat, fetal movement felt by a trained examiner, and visualization of the fetus with ultrasound confirmation. Presumptive signs are subjective and can have another etiology. These signs and symptoms include lack of menses, nausea, vomiting, fatigue, urinary frequency, and breast changes. The word “diagnostic” is not used to describe the condition of pregnancy.

CN: Physiological adaptation; CL: Analyze

32. 1. The serum pregnancy test measures human chorionic gonadotropin (hCG) in blood plasma and is highly accurate within 1 week after ovulation. The test is performed in a laboratory. Over-the-counter or home pregnancy tests are performed on urine and typically require higher levels of hCG to obtain a positive result. A positive pregnancy test is considered a probable sign of pregnancy. Certain conditions other than pregnancy, such as choriocarcinoma, can cause increased hCG levels.

CN: Reduction of risk potential; CL: Apply

33. 4. The hormone analyzed in most pregnancy tests is hCG. In the pregnant woman, trace amounts of hCG appear in the serum as early as 24 to 48 hours after implantation owing to the trophoblast production of this hormone. Prolactin, follicle-stimulating hormone, and luteinizing hormone are not used to detect pregnancy. Prolactin is the hormone secreted by the pituitary gland to prepare the breasts for lactation. Follicle-stimulating hormone is involved in follicle maturation during the menstrual cycle. Luteinizing hormone is responsible for stimulating ovulation.

CN: Reduction of risk potential; CL: Evaluate

34. 4. When using Nägele’s rule to determine the estimated date of birth, the nurse would count back 3 calendar months from the first day of the last menstrual period and add 7 days. This means the client’s estimated date is February 17.

CN: Health promotion and maintenance; CL: Apply

35. 4. The placenta does not produce testosterone. Human placental lactogen, hCG, estrogen, and progesterone are hormones produced by the

placenta during pregnancy. The hormone hCG stimulates the synthesis of estrogen and progesterone early in the pregnancy until the placenta can assume this role. Estrogen results in uterine and breast enlargement. Progesterone aids in maintaining the endometrium, inhibiting uterine contractility, and developing the breasts for lactation. The placenta also produces some nutrients for the embryo and exchanges oxygen, nutrients, and waste products through the chorionic villi.

CN: Health promotion and maintenance; CL: Evaluate

36. 4,3,2,1. While initially continuing to attempt to find the fetal heartbeat, the nurse can ask the client if the baby has been moving. This will give a quick idea of status. The next step would be to obtain different equipment and attempt to find the fetal heartbeat again. A simple statement of fact that the nurse cannot find the heartbeat and is taking steps to rule out equipment error is appropriate. Calling the **HCP**  would be the last step after it is determined that the baby does not have a heartbeat.

CN: Reduction of risk potential; CL: Synthesize

37. 1,2. Although ultrasounds are not considered part of routine care, the ultrasound is able to confirm the pregnancy, identify the major anatomic features of the fetus and possible abnormalities, and determine the gestational age by measuring crown-to-rump length of the embryo during the first trimester. At this time, the ultrasound cannot confirm that the fetus is viable. The ultrasound will provide information about fetal position; however, this information would be more important later in the pregnancy, not during the first trimester. The ultrasound would provide no information about nutrient supply for the fetus.

CN: Health promotion and maintenance; CL: Analyze

38. 2. This client is expressing a feeling of surprise about having a baby. Therefore, the nurse's best response would be to confirm the pregnancy, which is something that the client already suspects, and then ascertain how the client is feeling now that the suspicion is confirmed. Studies have shown that a common reaction to pregnancy is summarized as ambivalence or "someday, but not now." Such feelings are normal and are experienced by many women early in pregnancy. Offering a pamphlet on pregnancy does not

respond to the client's feelings. Telling the client that she should be delighted ignores, rather than addresses, the client's feelings. Also, doing so imposes the nurse's opinion on the client. Ambivalence is a common reaction to pregnancy. Telling the client that she should be delighted may lead to feelings of guilt. Asking about the client's concerns is premature until the nurse determines the client's overall feelings about the pregnancy.

CN: Psychosocial integrity; CL: Synthesize

39. 3. Women normally experience ambivalence when pregnancy is confirmed, even if the pregnancy was planned. Although the client's culture may play a role in openly accepting the pregnancy, most new mothers who have been ambivalent initially accept the reality by the end of the first trimester. Ambivalence also may be expressed throughout the pregnancy; this is believed to be related to the amount of physical discomfort. The nurse should become concerned and perhaps contact a social worker if the client expresses ambivalence in the third trimester. The client's statement reflects ambivalence, not fear. There is no evidence to suggest or imply that the client is rejecting the fetus. The client's statement reflects ambivalence about the pregnancy, not her ability to care for the newborn.

CN: Psychosocial integrity; CL: Analyze

40. 3. Couvade syndrome refers to the situation in which the expectant father experiences some of the discomforts of pregnancy along with the pregnant woman as a means of identifying with the pregnancy. Ptyalism is the term for excessive salivation. Mittelschmerz is the lower abdominal discomfort felt by some women during ovulation. Pica refers to an oral craving for substances such as clay or starch that some pregnant clients experience.

CN: Psychosocial integrity; CL: Analyze

41. 3. Maternal alcohol use may result in fetal alcohol syndrome, marked by mild-to-moderate mental retardation, physical growth retardation, central nervous system disorders, and feeding difficulties. Because there is no definitive answer as to how much alcohol can be safely consumed by a pregnant woman, it is recommended that pregnant clients be taught to abstain from drinking alcohol during pregnancy. Smoking and other medications also

may affect the fetus.

CN: Reduction of risk potential; CL: Apply

42. 4. An increase in clear, highly acidic vaginal secretions is a normal finding during pregnancy that aids in controlling the growth of pathologic bacteria. Vaginal secretions increase because of the influence of estrogen secretion and increased vaginal and cervical vascularity. The highly acidic nature of the vaginal secretions is caused by the action of *Lactobacillus acidophilus*, which increases the lactic acid content of the secretions. The increased acidity helps to make the vagina resistant to bacterial growth. During pregnancy, estrogen secretion fosters a glycogen-rich environment. Unfortunately, this glycogen-rich, acidic environment fosters the development of yeast (*Candida albicans*) infections, manifested by itching, burning, and a cheese-like vaginal discharge. If the client had a sexually transmitted infection, most likely she would have additional symptoms, such as lesions in the genital area or changes in color, consistency, or odor of the vaginal secretions. An increase in vaginal secretions does not help prevent expulsion of the mucus plug. The mucus plug is held in place by the cervix until the cervix becomes ripe.

CN: Health promotion and maintenance; CL: Analyze

43. 2. Measurement of the client's fundal height is a gross estimate of fetal gestational age. At 20 weeks' gestation, the fundal height should be at about the level of the client's umbilicus. The fundus typically is over the symphysis pubis at 12 weeks. A fundal height measurement between these two areas would suggest a fetus with a gestational age between 12 and 20 weeks. The fundal height increases approximately 1 cm/week after 20 weeks' gestation. The fundus typically reaches the xiphoid process at approximately 36 weeks' gestation. A fundal height between the umbilicus and the xiphoid process would suggest a fetus with a gestational age between 20 and 36 weeks. The fundus then commonly returns to about 4 cm below the xiphoid owing to lightening at 40 weeks. Additionally, pressure on the diaphragm occurs late in pregnancy. Therefore, a fundal height measurement near the xiphoid process with diaphragmatic compression suggests a fetus near the gestational age of 36 weeks or older.

CN: Health promotion and maintenance; CL: Apply

44. 2. The volume of fluid needed for amniocentesis is 15 mL, and this is usually available at 15 weeks' gestation. Fetal development continues throughout the prenatal period. Cells necessary for testing for hemophilia A are available during the entire pregnancy but are not accessible by amniocentesis until 12 weeks' gestation. Amniocentesis carries a slight risk of infection regardless of when the procedure is performed.

CN: Reduction of risk potential; CL: Apply

45. 4. The National Academy of Sciences Institute of Medicine and Health Canada recommend that women gain 25 to 35 lb (11.5 to 14.5 kg) during pregnancy. The pattern of weight gain is as important as the total amount of weight gained. Underweight women and women carrying twins should have a greater weight gain. Typically, women should gain 3.5 lb (1.6 kg) during the first trimester and then 1 lb (0.45 kg)/week during the remainder of the pregnancy (24 weeks) for a total of about 27 to 28 lb (12.2 to 12.7 kg). A weight gain of only 6.6 lb (3 kg) in the second and third trimesters is not normal because the client should be gaining about 1 lb (0.45 kg)/week, or 12 lb (5.4 kg) during the second and third trimesters. Gaining 12 lb (5.4 kg) during each trimester would total 36 lb (16.2 kg), which is slightly more than the recommended weight gain. In addition, nausea and vomiting during the first trimester can contribute to a lack of appetite and smaller weight gain during this trimester.

CN: Health promotion and maintenance; CL: Evaluate

46. 1,5. Green, leafy vegetables, such as asparagus, spinach, brussels sprouts, and broccoli, are rich sources of folic acid. Beans, peas, and lentils are also good sources. The pregnant woman needs to eat foods high in folic acid to prevent folic acid deficits, which may result in neural tube defects in the newborn. A well-balanced diet must include whole grains, dairy products, and fresh fruits; however, bananas are rich in potassium, seafood is rich in iodine, and yogurt is rich in calcium, not folic acid.

CN: Reduction of risk potential; CL: Apply

47. 3. Egg yolks and squash and other yellow vegetables are rich sources

of vitamin A. Buttermilk and cheese are good sources of calcium. Strawberries, broccoli, citrus fruits (such as oranges), and tomatoes are good sources of vitamin C, not vitamin A.

 CN: Basic care and comfort; CL: Evaluate

48. 1,3,4. Dairy products, fresh fruit, vegetables, and foods high in protein (like cheese and peanut butter) are excellent choices. Fried foods, such as chicken nuggets and tater tots, and foods such as cheeseburgers and buttered popcorn are high in fat; carbonated drinks such as diet colas, and foods such as pickles and ketchup contain large amounts of sodium. These foods can lead to an increase in ankle edema and promote weight gain from empty calories.

 CN: Health promotion and maintenance; CL: Apply

49. 1. Milk contains a large amount of calcium but contains no iron. Coffee, tea, and caffeinated soft drinks inhibit the absorption of iron. The vitamin C found in orange juice enhances the absorption of iron. Cream of wheat (1 cup/10 mg iron) and molasses (1 tbsp/3.0 mg iron) are considered excellent sources of iron as they contain the indicated amounts of iron.

 CN: Physiological adaptation; CL: Evaluate

50. 2. Magnesium aids in the synthesis of protein, nucleic acids, proteins, and fats. It is important for cell growth and neuromuscular function. Magnesium also activates the enzymes for metabolism of protein and energy. Calcium prevents demineralization of the mother's bones. Vitamin B₆ is important for amino acid metabolism. Folic acid assists in the development of neural pathways in the fetus.

 CN: Basic care and comfort; CL: Apply

51. 2. The nurse reports the results of the VDRL to the **HCP** . The pregnant client must be treated for syphilis to prevent perinatal transmission of the disease. The rubella titer and blood sugar values are within normal range. The blood type is not a significant factor in this situation.

 CN Reduction of risk potential; CL: Analyze

52. 2,3,4,5. During pregnancy, live virus immunizations are not

administered because of potential teratogenicity. These immunizations include chickenpox, rubella, mumps, smallpox, and live attenuated influenza vaccine. Vaccines containing killed viruses (tetanus, diphtheria, hepatitis B) may be administered, and in fact are recommended by the CDC if the immunizations are not up-to-date.

CN: Pharmacologic and parental therapies; CL: Analyze

53. 4. Although most multiparous women experience quickening at about 17½ weeks' gestation, some women may perceive it between 14 and 20 weeks' gestation because they have been pregnant before and know what to expect. Detecting movement early does not suggest a twin pregnancy. If the multiparous client does not experience quickening by 20 weeks' gestation, further investigation is warranted because the fetus may have died, the client has a hydatidiform mole, or the pregnancy dating is incorrect. There is no evidence that the client's expected date of birth is erroneous.

CN: Health promotion and maintenance; CL: Analyze

54. 1,2,3,4. Anyone could be a victim of intimate partner violence. Health care workers should routinely assess women for intimate partner violence. Pregnant teens have increased risk for not finishing school, smoking, and substance abuse. It is possible that the client is depressed, and her appearance and lack of eye contact are symptoms of her depression. The nurse expects the blood glucose screening test to be prescribed between 24 and 28 weeks' gestation to screen for gestational diabetes. HCG levels can identify the presence of a pregnancy or give information about an abnormal pregnancy. It would not be done at this time in a normal pregnancy.

CN: Health promotion and maintenance; CL: Apply

55. 2. Leopold's maneuvers involve abdominal palpation. The client should empty her bladder before the nurse palpates the abdomen. Doing so increases the client's comfort and makes palpation more accurate. Although breathing deeply may help to relax the client, it has no effect on the accuracy of the results of Leopold's maneuvers. The client does not need to drink a full glass of water before the examination. The client should be lying in a supine position with the head slightly elevated for greater comfort and with the knees drawn up slightly.

 CN: Health promotion and maintenance; CL: Apply

56. 1. Because the fetus is determined to be in an ROA, a vertex position, the convex portion of the fetus lying closest to the uterine wall would be located in the lower right quadrant of the abdomen. Placing the Doppler ultrasound over that area would produce the loudest fetal heart sounds.

 CN: Management of care; CL: Apply

57. 2. In left occipital anterior lie, the occiput faces the left anterior segment of the woman's pelvis. In left occipital transverse lie, the occiput faces the woman's left hip. In right occipital transverse lie, the occiput faces the woman's right hip. In right occipital anterior lie, the occiput faces the right anterior segment of the woman's pelvis.

CN: Physiological adaptation; CL: Apply

58. 1. Discoloration on the face that commonly appears during pregnancy, called *chloasma* (mask of pregnancy), usually fades postpartum and is of no clinical significance. The client who is bothered by her appearance may be able to decrease its prominence with ordinary makeup. Chloasma is not a sign of skin melanoma. It is not caused by dilated capillaries. Rather, it results from increased secretion of melanocyte-stimulating hormones caused by estrogen and progesterone secretion. No treatment is necessary for this condition.

CN: Health promotion and maintenance; CL: Apply

59. 4. Assessment of fundal height is a gross estimate of fetal growth. By 20 weeks' gestation, the height of the fundus should be at the level of the umbilicus, after which it should increase 1 cm for each week of gestation until approximately 36 weeks' gestation. Fundal height that is significantly different from that implied by the estimated gestational age warrants further evaluation (e.g., ultrasound examination) because it possibly indicates multiple pregnancy or fetal growth retardation. Fundal height estimation will not determine uterine activity or a need for increased weight gain. Leopold's maneuver will determine fetal position but is not typically done in the second trimester when the fetus is still freely moving.

CN: Health promotion and maintenance; CL: Apply

60. 2. One of the primary risks of amniocentesis is stimulation of the uterus and possible miscarriage. Other risks include hemorrhage from penetration of the placenta, infection of the amniotic fluid, and puncture of the fetus. Club foot has been associated with amniocentesis especially when it is performed before 15 weeks. There is little risk for fetal organ malformations.

CN: Reduction of risk potential; CL: Evaluate

61. 3. The client traveling by automobile should be advised to take intermittent breaks of 10 to 15 minutes, including walking, every 1 to 2 hours to stimulate the circulation, which becomes sluggish during long periods of sitting. Automobile travel is not contraindicated during pregnancy unless the

client develops complications. There is no set maximum number of hours allowed. The pregnant client should always wear a seat belt when traveling by automobile. The client should be aware of the nearest health care facility in the city to which she is traveling.

CN: Reduction of risk potential; CL: Apply

62. Seat belt safety is important for pregnant women because proper use reduces maternal mortality in car accidents. Both lap and shoulder belts are to be used. The lap portion of the belt is placed snugly but comfortably to fit under the abdominal bulge. Wearing the lap belt over the abdomen could increase the risk of uterine rupture and fetal complications due to belt tightening as the woman is propelled forward during an automobile accident. The shoulder belt is placed snugly across the shoulder, chest, and upper abdomen.

CN: Safety and infection control; CL: Apply

63. 3. Leg cramps are thought to result from excessive amounts of phosphorus absorbed from milk products. Straightening the knee and flexing the toes toward the chin is an effective measure to relieve leg cramps. Also, decreasing milk intake and supplementing with calcium lactate may help to reduce the cramping. Keeping the legs warm and elevating them are good preventive measures. Changing positions frequently aids venous return but is not helpful in relieving leg cramps. Alternately flexing and extending the legs

will not help to relieve the leg cramp. Lying prone in the bed is a difficult position for a client at 37 weeks' gestation to achieve and maintain because of the increase in abdominal size and therefore is not considered helpful.

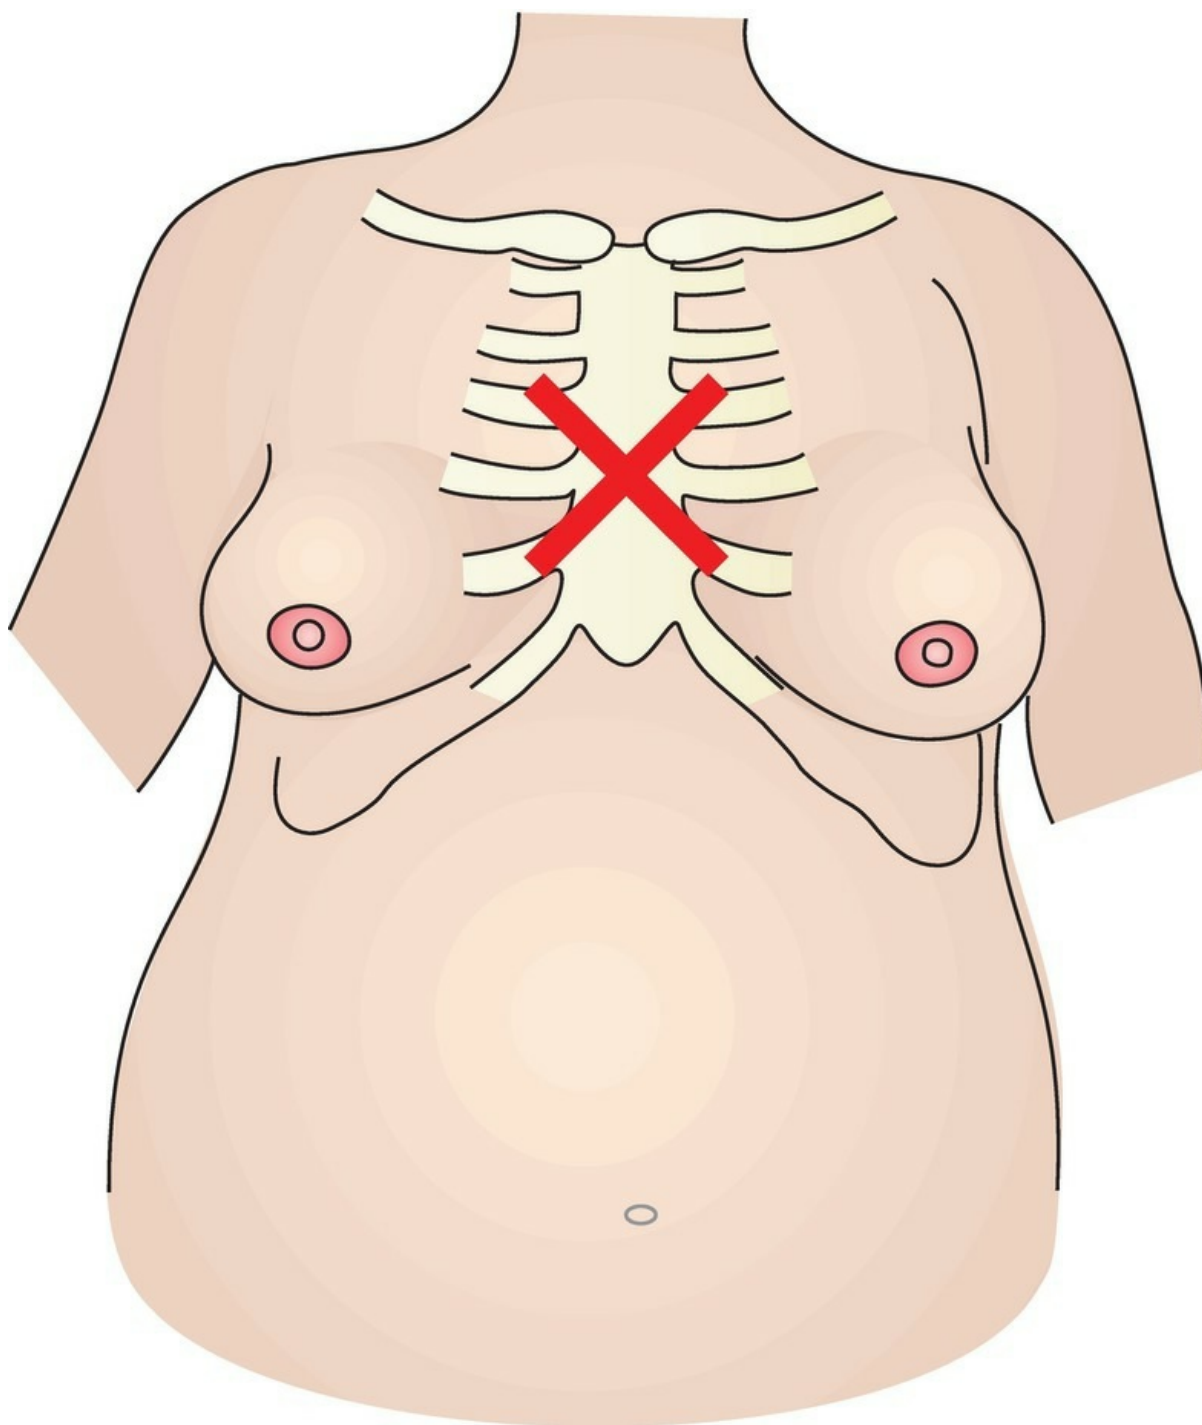

CN: Basic care and comfort; CL: Synthesize

64. The fist is placed against the middle of the woman's sternum, with backward thrusts until the foreign body is expelled. The pressure from the backward thrusts causes compression of the ribs, further adding to the chest and lung pressure, thereby forcing the foreign body to move upward.

CN: Safety and infection control; CL: Apply

65. 2. In the first maneuver, which is done with the nurse facing the client's head, both hands are used to palpate and determine which fetal body part (e.g., the head or buttocks) is in the fundus. This first maneuver helps to determine the presenting part of the fetus. In the second maneuver, also done with the nurse facing the client's head, the palms of both hands are used to

palpate the sides of the uterus and determine the location of the fetal back and spine. In the third maneuver, one hand gently grasps the lower portion of the abdomen just above the symphysis pubis to determine whether the fetal head is at the pelvic inlet. The fourth maneuver, done with the nurse facing the client's feet, determines the degree of fetal descent and flexion into the pelvis.

CN: Health promotion and maintenance; CL: Apply

66. 4. Increased alpha fetoprotein (AFP) is one of the four laboratory values in a maternal quad screen. The labs are *human chorionic gonadotropin*, *estriol*, and *inhibin-A*. Increased AFP levels are associated with neural tube defects, such as spina bifida, anencephaly, and encephalocele. Ultrasonography is used to confirm a neural tube defect only when AFP levels are increased. Because AFP levels are usually highest at 15 to 18 weeks' gestation, this is the optimum time for testing. Performing the test after this time leads to inaccurate results. The client's blood, not urine, is used for the sample.

CN: Reduction of risk potential; CL: Create

67. 1. Prenatal care is commonly the most critical factor influencing pregnancy outcome. This is especially true for adolescents because the most significant medical complication in pregnant adolescents is pregnancy-induced hypertension. Continued prenatal care helps to allow for early detection and prompt intervention should the complication arise. Other risks for adolescents include low-birth-weight infant, preterm labor, iron deficiency anemia, and cephalopelvic disproportion. Gestational diabetes can occur with any pregnancy regardless of the age of the mother. Generally, all first-time mothers need instruction related to discomforts. Adolescent mothers have better nutrition when they attend group classes and are subject to peer pressure. No evidence demonstrates that most adolescents lack support systems. Fathers may abandon mothers at any time during the pregnancy; other fathers, regardless of age, are supportive throughout the pregnancy.

CN: Health promotion and maintenance; CL: Apply

68. 3. Colostrum is usually secreted by about the 16th week of gestation in

preparation for breast-feeding. Growth of the milk ducts is greatest in the last trimester, not in the first 8 weeks of gestation. Enlargement of the breasts is usually caused by estrogen, not progesterone. Darkening of the areola can occur as early as the 6th week of gestation.

CN: Health promotion and maintenance; CL: Create

69. 2,4,5. Understanding of breast-feeding education is demonstrated by statements involving knowledge of the several positions available for comfortable breast-feeding, oxytocin release from the pituitary leading to a let-down reflex and uterine contractions for involution, and feeding cues helpful in successful breast-feeding (because waiting until the infant is hungry and crying is stressful). Breast size does not ensure successful breast-feeding. Mastitis is an infectious process and is not influenced by latching on.

CN: Basic care and comfort; CL: Evaluate

70. 2. During pregnancy, the circulatory system undergoes tremendous changes. Cardiac output increases by 25% to 50%, and circulatory blood volume increases by about 30%. The client may experience transient hypotension and dizziness with sudden position changes. Early in pregnancy, there is a slight increase in the temperature, and clients may attribute this to a sinus infection or a cold. The client may feel warm, but this sensation is transient. The level of circulating fibrinogen increases as much as 50% during pregnancy, probably because of increased estrogen. Any calf tenderness should be reported because it may indicate a clot. Late in pregnancy, the posterior pituitary gland secretes oxytocin. The client may experience painful Braxton Hicks contractions or early labor symptoms.

CN: Health promotion and maintenance; CL: Create

71. 1. The fetal biophysical profile includes fetal breathing movements, fetal body movements, tone, amniotic fluid volume, and fetal heart rate reactivity. A reactive nonstress test is a sign of fetal well-being and does not require further evaluation. A nonreactive nonstress test requires further evaluation. A contraction stress test or oxytocin challenge test should be performed only on women who are at risk for fetal distress during labor. The contraction stress test is rarely performed before 28 weeks' gestation because of the possibility of initiating labor. Percutaneous umbilical cord sampling

requires the insertion of a needle through the abdomen to obtain a fetal blood sample.

 CN: Reduction of risk potential; CL: Apply

72. 1,3,4,5. The fetus does go through sleep cycles, rendering it less likely to move while it is asleep. Blood glucose does cross the placenta and can affect fetal movement. Cigarette smoking causes carbon monoxide to cross the placenta, which reduces fetal oxygen. Pregnant women are more likely to notice fetal movement while they are sitting or lying down, and time of day often determines this. Most pregnant women notice fetal movement in the evening. Barometric pressure does not affect fetal activity in utero.

 CN: Health promotion and maintenance; CL: Analyze.

73. 3. The purpose of Kegel exercises is to strengthen the perineal muscles in preparation for the labor process. These movements strengthen the pubococcygeal muscle, which surrounds the urinary meatus and vagina. No evidence is available to support the idea that these exercises reduce the risk of hemorrhoids, alleviate lower back discomfort, or strengthen the abdominal muscles.

 CN: Basic care and comfort; CL: Apply

74. 4. During the third trimester, it is not uncommon for clients to have dreams or fantasies about the baby. Sometimes the dreams are about infants who are malformed or, in this example, covered with hair. There is no evidence to suggest that the client is trying to cope with becoming a parent. Having dreams about the baby does not mean that labor will begin soon.

 CN: Psychosocial integrity; CL: Synthesize

75. 1. Insomnia in the later part of pregnancy is not uncommon because the client has difficulty getting into a position of comfort. This is further compounded by frequent nocturia. The best suggestion would be to advise the client to practice relaxation techniques before bedtime. The client should avoid caffeine products such as chocolate and coffee before going to bed because caffeine is a stimulant. Alcohol consumption, regardless of the type or amount, should be avoided. Exercise is advised during the day, but it should be avoided before bedtime because exercise can stimulate the client

and decrease the client's ability to fall asleep.

CN: Basic care and comfort; CL: Apply

76. 3. The client needs further instruction when she says it is permissible to sit in a hot tub for 20 minutes to relax after working. Hot tubs and saunas should be avoided, particularly in the first trimester, because their use can lead to maternal hyperthermia, which is associated with fetal anomalies such as central nervous system defects. The client should use nonskid pads in the shower or bath to avoid slipping because the client's center of gravity has shifted and she may fall. The client should avoid using soap on the nipples to prevent removal of the natural protective oils. Douching is not recommended for pregnant women because it can destroy the normal flora and increase the client's risk of infection.

CN: Health promotion and maintenance; CL: Evaluate

The Pregnant Client in Birth Preparation Classes

77. 3,4,5,6. During the third trimester of pregnancy, the woman experiments with maternal and caregiver roles and may make plans for changes in employment, managing household tasks, and/or childcare. The woman is also concerned about safety and passage through labor and birth. Other psychological tasks include preparation of the nursery, being tired of the pregnancy, and being introspective. A woman will begin to see herself as someone different from the fetus in the second trimester. Additionally, the mother may fantasize about the infant during the second trimester and be concerned about her changing body image. She may experience ambivalence about pregnancy in the first trimester.

CN: Psychosocial integrity; CL: Create

78. 4. Pregnancy creates changes in the mother and father. Being considerate, accepting changes, and being supportive of the current situation are considered acceptable responses by the father, rather than feeling irritation about these changes. Expressing concern with the financial changes pregnancy and an expanded family include is normal. The first trimester involves the client and family feeling ambivalent about pregnancy and moving toward acceptance of the changes associated with pregnancy.

Maternal acceptance of the pregnancy and a subsequent change in her focus are normal occurrences.

CN: Health promotion and maintenance; CL: Analyze

79. 4. Thyroid enlargement and increased basal body metabolism are common occurrences during pregnancy. Human placental lactogen enhances milk production. Estrogen is responsible for hyperpigmentation and vascular skin changes. Progesterone relaxes smooth muscle in the respiratory tract.

CN: Health promotion and maintenance; CL: Create

80. 1. Although sex is not easily discerned at 9 to 12 weeks, external genitalia are developed at this period of fetal development. Myelination of the nerves begins at about 20 weeks' gestation. Brown fat stores develop at approximately 21 to 24 weeks. Air ducts and alveoli develop later in the gestational period, at approximately 25 to 28 weeks.

CN: Health promotion and maintenance; CL: Apply

81. 2. Monozygotic twinning is independent of race, age, parity, or heredity. Monozygotic twins result from the fertilization of one ovum that cleaves completely into two embryos. Dizygotic twinning occurs with the fertilization of more than one ovum during conception. Dizygotic twins may be of the same sex or different sexes. Dizygotic twinning is correlated with increased parity, becoming pregnant within 1 month after stopping oral contraception, and infertility treatments. A primigravid client is less likely to conceive dizygotic twins.

CN: Health promotion and maintenance; CL: Apply

82. 1,3,2,4. Engagement refers to the fetus' entering the true pelvis and occurs before descent in primiparas and concurrently in multiparous women. If the head is the presenting part, the normal maneuvers during labor and birth are (in order) descent, flexion, internal rotation, extension, external rotation, and expulsion. These maneuvers are called the *cardinal movements*. They occur as the fetal head passes through the maternal pelvis during the normal labor process.

CN: Health promotion and maintenance; CL: Apply

83. 1. In a normal birth and for the first 24 hours postpartum, a total blood loss not exceeding 500 mL is considered normal. Blood loss during childbirth is almost always estimated because it provides a valuable indicator for possible hemorrhage. A blood loss of 1,000 mL is considered hemorrhage.

CN: Health promotion and maintenance; CL: Apply

84. 2. Although the amniotic fluid promotes normal prenatal development by allowing symmetric development, it does not provide the fetus with nutrients. Rather, nutrients are provided by the placenta. The amniotic fluid does help dilate the cervix once labor begins by pressure and gravity forces. The amniotic fluid helps to protect the fetus from injury by cushioning against impact of the maternal abdomen and allows room and buoyancy for fetal movement. The amniotic fluid and sac keep the fetus at a stable temperature by maintaining a neutral thermal environment.

CN: Health promotion and maintenance; CL: Evaluate

85. 1. Pelvic rocking helps to relieve backache during pregnancy and early labor by making the spine more flexible. Deep breathing exercises assist with relaxation and pain relief during labor. Tailor sitting and squatting help stretch the perineal muscles in preparation for labor.

CN: Health promotion and maintenance; CL: Analyze

86. 1,2,4. Pain during the first stage of labor is primarily caused by hypoxia of the uterine and cervical muscle cells during contraction, stretching of the lower uterine segment, dilatation of the cervix and perineum, and pressure on adjacent structures. Ambulating will assist in increasing circulation of blood to the area and relaxing the muscles. Slow chest breathing is appropriate during the first stage of labor to promote increased oxygenation as well as relaxation. The woman or her coach can lightly massage the abdomen (effleurage) while using slow chest breathing. Chest breathing and massaging increase oxygenation and relaxation of uterine muscles. Pain medication is not used during the first stage of labor because most medications will slow labor; anesthesia may be considered during the second stage of labor. Sipping ice water, while helpful for maintaining hydration, will not be useful as a pain management strategy.

CN: Health promotion and maintenance; CL: Synthesize

87. 4. With true labor, the contractions are felt first in the lower back and then the abdomen. They gradually increase in frequency and duration and do not disappear with ambulation, rest, or sleep. In true labor, the cervix dilates and effaces. Walking tends to increase true contractions. False labor contractions disappear with ambulation, rest, or sleep. False labor contractions commonly remain the same in duration and frequency. Clients who are experiencing false labor may have pain, even though the contractions are not very effective.

CN: Health promotion and maintenance; CL: Apply

88. 4. Pelvic tilt exercises are useful to alleviate backache during pregnancy and labor but are not useful for the pain from contractions. Biofeedback (a conscious effort to control the response to pain), effleurage (light uterine massage), and guided imagery (focusing on a pleasant scene) are appropriate pain relief techniques to practice before labor begins. Various breathing exercises also can help to alleviate the discomfort from contraction pain.

CN: Health promotion and maintenance; CL: Evaluate

89. 2. Increased vaginal discharge is normal during pregnancy, but yellow-gray frothy discharge with local itching is associated with infection (e.g., *Trichomonas vaginalis*). The client's symptoms must be further assessed by a health professional because the client needs treatment for this condition. *T. vaginalis* infection is commonly treated with metronidazole; however, this drug is not used in the first trimester. In the first trimester, the typical treatment is topical clotrimazole. Although a yeast infection is associated with vaginal itching, the vaginal discharge is cheese-like. Furthermore, because the client may have a serious vaginal infection, over-the-counter medications are not advised until the client has been evaluated. Douching is not recommended during pregnancy because it would predispose the client to an ascending infection. The client is not exhibiting signs and symptoms of preterm labor, such as contractions or leaking fluid. And although the client's problems are suggestive of a *T. vaginalis* infection, which can lead to preterm labor and premature rupture of the membranes, further evaluation is needed

to confirm the cause of the infection.

CN: Health promotion and maintenance; CL: Synthesize

90. 2. During pregnancy, urinary tract infections are more common because of urinary stasis. Clients need instructions about increasing fluid volume intake. Plasma volume increases during pregnancy. The increase in plasma volume is more pronounced and occurs earlier than does the increase in red blood cell mass, possibly resulting in physiologic anemia. Peripheral vascular resistance decreases during pregnancy, providing a relatively stable blood pressure. Hemoglobin levels decrease during pregnancy even though there is an increase in blood volume.

CN: Health promotion and maintenance; CL: Apply

The Pregnant Client with Risk Factors

91. 4. For the Rh-negative client who may be pregnant with an Rh-positive fetus, an indirect Coombs test measures antibodies in the maternal blood. Titers should be performed monthly during the first and second trimesters and biweekly during the third trimester and the week before the due date.

CN: Health promotion and maintenance; CL: Apply

92. 4. A maternal quad screen testing is done to screen for genetic and neural tube abnormalities between the 15th and 18th weeks of gestation. The four tests included are an alpha fetoprotein (AFP), *human chorionic gonadotropin*, estriol, and inhibin-A. Abnormally high levels of AFP found in maternal serum may be indicative of neural tube defects such as anencephaly and spina bifida. Low levels may indicate trisomy 21 (Down syndrome). Beta strep testing is done in the third trimester. Chorionic villus sampling is done as early as 10 weeks' gestation to detect anomalies. Ultrasound testing may be done in the first trimester to determine fetal viability and in the third trimester to determine pelvic adequacy and fetal or placental position.

CN: Reduction of risk potential; CL: Apply

93. 1,2,5. Prenatal care includes a general supplementation of 400 mcg of folic acid, and clients with a history of gastric bypass should be referred to a

dietician to determine adequate nutrient intake. All pregnant clients have their urine routinely checked for protein and sugar. There is no indication for checking glucose levels at each prenatal visit in clients who have undergone gastric bypass. Gastric bypass clients are not at risk of gaining all of their weight back. No evidence supports implementing nonstress tests at 20 weeks.

CN: Health promotion and maintenance; CL: Create

94. 2. According to both the New York Heart Association and the Canadian Cardiovascular Society, this client would fit under class II because she is symptomatic with increased activity (dyspnea with exertion). Class II clients have cardiac disease and a slight limitation in physical activity. When physical activity occurs, the client may experience angina, difficulty breathing, palpitations, and fatigue. All of the client's other symptoms are within normal limits.

CN: Management of care; CL: Analyze

95. 1,2,5. The test result indicates that the mother has an active hepatitis infection and is a carrier. Hepatitis B immune globulin at birth provides the infant with passive immunity against hepatitis B and serves as a prophylactic treatment. Additionally, the infant will be started on the vaccine series of three injections. The infant should not be screened or isolated because the infant is already hepatitis B positive. As with all clients, universal precautions should be used and are sufficient to prevent transmission of the virus. Women who are positive for hepatitis B surface antigen are able to breast-feed.

CN: Management of care; CL: Create

96. 4. Asthma medications and bronchodilators should be continued during pregnancy as prescribed before the pregnancy began. The medications do not cause harm to the mother or fetus. Regular use of asthma medication will usually prevent asthma attacks. Prevention and limitation of an asthma attack is the goal of care for a client who is or is not pregnant and is the appropriate care strategy. During an asthma attack, oxygen needs continue as with any pregnant client, but the airways are edematous, decreasing perfusion. Asthma exacerbations during pregnancy may occur as a result of infrequent use of medication rather than as a result of the pregnancy.

CN: Pharmacological and parenteral therapies; CL: Evaluate

97. 2. The nurse seeing this client should refer her to a **HCP**  for further evaluation of the pain. This referral would allow a more definitive diagnosis and medical interventions that may include surgery. Referral would occur because of her high pain rating as well as the other symptoms, which suggest gallbladder disease. During pregnancy, the gallbladder is under the influence of progesterone, which is a smooth muscle relaxant. Because bile does not move through the system as quickly during pregnancy, bile stasis and gallstone formation can occur. Although education should be a continuous strategy, with pain at this level, a brief explanation is most appropriate. Major emphasis should be placed on determining the cause and treating the pain. It is not appropriate for the nurse to diagnose pain at this level as heartburn. - Discussing nutritional strategies to prevent heartburn are appropriate during pregnancy, but not in this situation. Acetaminophen is an acceptable medication to take during pregnancy but should not be used on a regular basis as it can mask other problems.

CN: Management of care; CL: Synthesize

98. 3. A fetus that has died and is retained in utero places the mother at risk for disseminated intravascular coagulation (DIC) because the clotting factors within the maternal system are consumed when the nonviable fetus is retained. The longer the fetus is retained in utero, the greater the risk of DIC. This client has no risk factors, history, or signs and symptoms that put her at risk for abruptio placentae such as sharp pain and “woody,” firm consistency of the abdomen. HELLP syndrome is a complication of preeclampsia that does not occur before 20 weeks’ gestation unless a molar pregnancy is present. There is no evidence that she is threatening to abort as she has no cramping or vaginal bleeding.

CN: Management of care; CL: Analyze

99. 2. A blood pressure reading of 138/88 mm Hg is nearing hypertension range and could be a sign of developing gestational hypertension. Conversely, the client may be experiencing “white coat” syndrome or could be anxious during the prenatal visit. In order to obtain an accurate blood pressure reading, the nurse should allow the woman to rest for a period of time and recheck the blood pressure in the same arm and while the woman is in the same position. This blood pressure is considered approaching high. All

other vitals are within normal range.

CN: Physiological adaptation; CL: Analyze

100. 2. Chorionic villus sampling (CVS) can be performed from approximately 8 to 12 weeks' gestation, while amniocentesis cannot be performed until between 11 weeks' gestation and the end of the pregnancy. Eleven weeks' gestation is the earliest possible time within the pregnancy to obtain a sufficient amount of amniotic fluid to sample. Because CVS take a piece of membrane surrounding the infant, this procedure can be completed earlier in the pregnancy. Amniocentesis and chorionic villus sampling identify the genetic makeup of the fetus in its entirety, rather than a portion of it. Laboratory analysis of chorionic villus sampling takes less time to complete. Both procedures place the fetus at risk, and postprocedure teaching asks the client to report the same complicating events (bleeding, cramping, fever, and fluid leakage from the vagina).

CN: Management of care; CL: Evaluate

101. 4. Additional teaching is needed when the parent says that adolescents are at greater risk for congenital anomalies. Although adolescents are at greater risk for denial of the pregnancy, lack of prenatal care, low-birth-weight infant, cephalopelvic disproportion, anemia, and nutritional deficits and have a higher maternal mortality rate, studies reveal that congenital anomalies are not more common in adolescent pregnancies.

CN: Health promotion and maintenance; CL: Evaluate

102. 4. With a spontaneous abortion, many clients and their partners feel an acute sense of loss. Their grieving commonly includes feelings of guilt, which may be expressed as wondering whether the woman could have done something to prevent the loss. Anger, sadness, and disappointment are also common emotions after a pregnancy loss. Ambivalence, anxiety, and fear are not common emotions after a spontaneous abortion.

CN: Psychosocial integrity; CL: Analyze

103. 1. Hydroxyzine has a tranquilizing effect and also decreases nausea and vomiting. It does not decrease fluid retention, reduce pain, decrease uterine cramping, or promote uterine contractility. One of the adverse effects

of the medication is sleepiness. Ibuprofen may decrease pain from uterine cramping. Oxytocin may be used to increase uterine contractility.

CN: Pharmacological and parenteral therapies; CL: Evaluate

104. 3. The death of a fetus at any time during pregnancy is a tragedy for most parents. After a spontaneous abortion, the client and family members can be expected to suffer from grief for several months or longer. When offering support, a simple statement such as “I am truly sorry you lost your baby” is most appropriate. Therapeutic communication techniques help the client and family understand the meaning of the loss, move less stressfully through the grief process, and share feelings. Asking the client whether she is experiencing a great deal of uterine pain is inappropriate because this is a “yes-no” question and doesn’t allow the client to express her feelings. Saying that the embryo was defective is inappropriate because this may lead the client to think that she contributed to the fetus’s demise. This is not the appropriate time to discuss embryonic or fetal malformations. However, the nurse should explain to the client that this situation was not her fault. Telling the client that she should not get pregnant again too soon is not therapeutic and discounts the feelings of the expectant mother who had already begun to bond with the fetus.

CN: Psychosocial integrity; CL: Apply

105. 4. Rh sensitization can be prevented by Rho(D) immune globulin, which clears the maternal circulation of Rh-positive cells before sensitization can occur, thereby blocking maternal antibody production to Rh-positive cells. Administration of this drug will not prevent future Rh-positive fetuses, nor will it prevent future abortions. An antibody response will not occur to Rh-negative cells. Rh-negative mothers do not develop sensitivities if the fetus is also Rh negative.

CN: Pharmacological and parenteral therapies; CL: Apply

106. 2. The client with leg varicosities should take frequent rest periods with the legs elevated above the hips to promote venous circulation. The client should avoid constrictive clothing, but support hose that reach above the varicosities may help alleviate the pain. Contracting and relaxing the feet and ankles twice daily is not helpful because it does not promote circulation.

Taking a leave of absence from work may not be possible because of economic reasons. The client should try to rest with her legs elevated or walk around for a few minutes every 2 hours while on the job.

 CN: Reduction of risk potential; CL: Synthesize

107. 4. The client is reporting symptoms typically associated with herpes genitalis. Some women have no symptoms of gonorrhea. Others may experience vaginal itching and a thick, purulent vaginal discharge. *C. trachomatis* infection in women is commonly asymptomatic, but symptoms may include a yellowish discharge and painful urination. The first symptom of syphilis is a painless chancre.

 CN: Physiological adaptation; CL: Apply

108. 1. The client may need surgery to remove a ruptured fallopian tube where the pregnancy has occurred, and the nurse is usually responsible for witnessing the signature on the **informed consent** . Typically, if bleeding is occurring, it is internal, and there is only scant vaginal bleeding with no discoloration. The nurse cannot determine whether the fallopian tube can be salvaged; this can be accomplished only during surgery. If the tube has ruptured, it must be removed. If the tube has not ruptured, a linear salpingostomy may be done to salvage the tube for future pregnancies. With an ectopic pregnancy, although the client is experiencing abdominal pain, she is not having uterine contractions.

 CN: Physiological adaptation; CL: Synthesize

Managing Care, Quality, and Safety for Childbearing Clients

109. 2. Late decelerations during an oxytocin challenge test indicate that the infant is not receiving enough oxygen during contractions and is exhibiting signs of uteroplacental insufficiency. This client would need further medical intervention. Fetal movement 6 times in 2 hours is adequate in a healthy fetus, and a biophysical profile of 9 indicates that the risk of fetal asphyxia is rare. A reactive nonstress test informs the **HCP**  that the fetus has 2 fetal heart rate accelerations of 15 beats per minute above baseline and

lasting for 15 seconds within a 20-minute period, which is a normal result and an indication of fetal well-being.

CN: Management of care; CL: Evaluate

110. 1. Folic acid supplementation is recommended to prevent neural tube defects and anemia in pregnancy. Deficiencies increase the risk of - hemorrhage during birth as well as infection. The recommended dose prior to pregnancy is 400 mcg/day; while breast-feeding and during pregnancy, the recommended dosage is 400 to 800 mcg/day. Blood glucose levels are not regulated by the intake of folic acid. Vitamin C potentiates the absorption of iron and is also associated with blood clotting or collagen formation.

CN: Reduction of risk potential; CL: Apply

111. 3,4,1,2. The first client to be seen should be the postpartum mother who is fearful of shaking her infant. Postpartum depression is a disorder that may occur during the first year postpartum but peaks at 4 weeks postpartum, prior to menses, or upon weaning. As a single mother, this client may not have support, a large factor putting women at risk. Other factors accentuating risk include prior depressive or bipolar illness and self-dissatisfaction. Second, the nurse should see the 16-week antenatal client, who is likely experiencing round ligament syndrome. At this point in the pregnancy, the uterus is stretching into the abdomen causing this type of pain. The pain is on the wrong side to be attributed to appendicitis or gallbladder disease. Nursing interventions to ease the pain include a heating pad or bringing the legs toward the abdomen. The nurse should next see the primigravid client who states she is not feeling well because she is exhibiting signs and symptoms of discomfort experienced by most women in the first trimester. The multiparous client at 32 weeks' gestation is the lowest priority as she is physically well, while the other clients have physical and psychological problems. In most emergency department situations, she may not be seen by medical or nursing staff but would be given the names of **HCPs** in the reception area.

CN: Management of care; CL: Synthesize

112. 1,2,3,4. The same safety policies apply to both inpatient and outpatient settings and are adapted to the individual specialty. Handwashing

and use of two client identifiers are standard procedures. Abbreviations that are used for inpatient are also used for outpatient as the same mistakes can occur in either setting with confusion in spelling or interpretation of letters and numbers. Preprocedure verification with name and procedure is used in the operating room, inpatient, and in ambulatory settings regardless of the procedure. It is logical to place clients with obvious communicable diseases by themselves, but nausea and vomiting are a “normal” situation in early pregnancy and not contagious.

CN: Risk reduction; CL: Evaluate

Complications of Pregnancy

- The Pregnant Client with Preeclampsia or Eclampsia
- The Pregnant Client with a Chronic Hypertensive Disorder
- The Pregnant Client with Third-Trimester Bleeding
- The Pregnant Client with Preterm Labor
- The Pregnant Client with Premature Rupture of the Membranes
- The Pregnant Client with Diabetes Mellitus
- The Pregnant Client with Heart Disease
- The Client with an Ectopic Pregnancy
- The Pregnant Client with Hyperemesis Gravidarum
- The Client with a Gestational Trophoblastic Disease
- The Pregnant Client with Miscellaneous Complications
- Managing Care, Quality, and Safety for Pregnant Clients
- Answers, Rationales, and Test-Taking Strategies

The Pregnant Client with Preeclampsia or Eclampsia

1. A laboring client with preeclampsia is prescribed magnesium sulfate 2 g/h IV piggyback. The pharmacy sends the IV to the unit labeled *magnesium sulfate 20 g/500 mL normal saline*. To deliver the correct dose, the nurse should set the pump to deliver how many milliliters per hour? Record your answer using one decimal place.

_____ mL.

2. A 32-year-old multigravida returns to the clinic for a routine prenatal visit at 36 weeks' gestation. The assessments during this visit include blood pressure, 140/90 mm Hg; pulse, 80 beats/min; respiratory rate, 16

breaths/min. What further information should the nurse obtain to determine if this client is becoming preeclamptic?

- ☐ 1. headaches
- ☐ 2. blood glucose level
- ☐ 3. proteinuria
- ☐ 4. peripheral edema

3. The nurse is instructing a preeclamptic client about monitoring the movements of her fetus to determine fetal well-being. Which statement by the client indicates that she needs further instruction about when to call the healthcare provider (HCP) concerning fetal movement?

- ☐ 1. “if the fetus is becoming less active than before”
- ☐ 2. “if it takes longer each day for the fetus to move 10 times”
- ☐ 3. “if the fetus stops moving for 12 hours”
- ☐ 4. “if the fetus moves more often than three times an hour”

4. A 29-year-old multigravida at 37 weeks’ gestation is being treated for severe preeclampsia and has magnesium sulfate infusing at 3 g/h. To maintain safety for this client, the **priority** intervention is to:

- ☐ 1. maintain continuous fetal monitoring.
- ☐ 2. encourage family members to remain at bedside.
- ☐ 3. assess reflexes, clonus, visual disturbances, and headache.
- ☐ 4. monitor maternal liver studies every 4 hours.

5. At 32 weeks’ gestation, a 15-year-old primigravid client who is 5 feet, 2 inches (151.7 cm) has gained a total of 20 lb (9.1 kg), with a 1-lb (0.45-kg) gain in the last 2 weeks. Urinalysis reveals negative glucose and a trace of protein. The nurse should advise the client that which factor increases her risk for preeclampsia?

- ☐ 1. total weight gain
- ☐ 2. short stature
- ☐ 3. adolescent age group
- ☐ 4. trace proteinuria

6. After instructing a primigravid client at 38 weeks’ gestation about how preeclampsia can affect the client and the growing fetus, the nurse realizes

that the client needs additional instruction when she says that preeclampsia can lead to which problem?

- ☐ 1. hydrocephalic infant
- ☐ 2. abruptio placentae
- ☐ 3. intrauterine growth restriction
- ☐ 4. poor placental perfusion

7. A nurse is completing a prenatal assessment on a woman who is 28 weeks' pregnant with gestational hypertension. Which findings should be reported to the primary care provider? Select all that apply.

- ☐ 1. dull headache
- ☐ 2. edematous feet
- ☐ 3. blurred vision
- ☐ 4. 1+ urine protein
- ☐ 5. fundal height of 28 cm

8. When teaching a multigravid client diagnosed with mild preeclampsia about nutritional needs, which type of diet should the nurse discuss?

- ☐ 1. high-residue diet
- ☐ 2. low-sodium diet
- ☐ 3. regular diet
- ☐ 4. high-protein diet

9. A woman with preeclampsia is receiving magnesium sulfate via infusion pump at 1 g/h. The nurse's assessment includes temperature 36.7°C; pulse 78; respirations 12/minute; B/P 128/82; urinary output 90 mL in last 4 hours via Foley catheter; patellar-tendon reflex absent; ankle clonus absent; fetal heart rate 120 beats/min; cervix 4 cm dilated, 80% effaced, station -1.

Which is the **most** appropriate action for the nurse to take?

- ☐ 1. Assess the Foley catheter for kinks in the drainage tubing, and obtain a urine sample.
- ☐ 2. Document findings, and continue to monitor her progress in labor.
- ☐ 3. Discontinue the magnesium sulfate infusion, and notify the healthcare provider (HCP).
- ☐ 4. Increase fluid intake intravenously, and measure intake and output.

10. A primigravid client at 38 weeks' gestation diagnosed with mild preeclampsia calls the clinic nurse to say she has had a continuous headache for the past 2 days accompanied by nausea. The client does not want to take aspirin. The nurse should tell the client:

- ☐ 1. "Take two acetaminophen tablets. They are not as likely to upset your stomach."
- ☐ 2. "I think the healthcare provider should see you today. Can you come to the clinic this morning?"
- ☐ 3. "You need to lie down and rest. Have you tried placing a cool compress over your head?"
- ☐ 4. "I will ask the healthcare provider to call in a prescription for nausea medications. What is your pharmacy's number?"

11. When preparing the room for admission of a multigravid client at 36 weeks' gestation diagnosed with severe preeclampsia, which item is **most** important for the nurse to obtain?

- ☐ 1. oxytocin infusion solution
- ☐ 2. disposable tongue blades
- ☐ 3. portable ultrasound machine
- ☐ 4. padding for the side rails

12. A client who is 34 weeks pregnant is admitted to the labor and birth room with the diagnosis of preeclampsia. The client's vital signs are as follows: blood pressure 149/92 mm Hg; pulse, 62 beats/min; respiratory rate, 18 breaths/min; temperature, 98.4°F (36.8°C). What is the **priority** intervention?

- ☐ 1. Encourage the client to lie in a lateral position.
- ☐ 2. Administer an antihypertensive agent.
- ☐ 3. Notify the healthcare provider (HCP) of the client's blood pressure.
- ☐ 4. Check the cervix.

13. The primary healthcare provider (HCP) prescribes intravenous magnesium sulfate for a primigravid client at 38 weeks' gestation diagnosed with severe preeclampsia. Which medication would be **most** important for the nurse to have readily available?

- ☐ 1. diazepam
- ☐ 2. hydralazine
- ☐ 3. calcium gluconate
- ☐ 4. phenytoin

14. For the client who is receiving intravenous magnesium sulfate for severe preeclampsia, which assessment finding would alert the nurse to suspect hypermagnesemia?

- ☐ 1. decreased deep tendon reflexes
- ☐ 2. cool skin temperature
- ☐ 3. rapid pulse rate
- ☐ 4. tingling in the toes

15. A client at 28 weeks' gestation presents to the emergency department with a "splitting headache." What actions are indicated by the nurse at this time? Select all that apply.

- ☐ 1. Reassure the client that headaches are a normal part of pregnancy.
- ☐ 2. Assess the client for vision changes or epigastric pain.
- ☐ 3. Obtain a nonstress test.
- ☐ 4. Assess the client's reflexes and presence of clonus.
- ☐ 5. Determine if the client has a documented ultrasound for this pregnancy.

16. Which outcome would the nurse identify as the **priority** to achieve when developing the plan of care for a primigravid client at 38 weeks' gestation who is hospitalized with severe preeclampsia and receiving intravenous magnesium sulfate?

- ☐ 1. decreased generalized edema within 8 hours
- ☐ 2. decreased urinary output during the first 24 hours
- ☐ 3. sedation and decreased reflex excitability within 48 hours
- ☐ 4. absence of any seizure activity during the first 48 hours

17. The nurse is administering intravenous magnesium sulfate as prescribed for a client at 34 weeks' gestation with severe preeclampsia. What are desired outcomes of this therapy? Select all that apply.

- ☐ 1. temperature, 98°F (36.7°C); pulse, 72 beats/min; respiratory rate, 14 breaths/min

- ☐ 2. urinary output less than 30 mL/h
- ☐ 3. fetal heart rate with late decelerations
- ☐ 4. blood pressure of less than 140/90 mm Hg
- ☐ 5. deep tendon reflexes 2+
- ☐ 6. magnesium level = 5.6 mg/dL (2.8 mmol/L)

18. Soon after admission of a primigravid client at 38 weeks' gestation with severe preeclampsia, the primary healthcare provider (HCP) prescribes a continuous intravenous infusion of 5% dextrose in Ringer's solution and 4 g of magnesium sulfate. While the medication is being administered, which assessment finding should the nurse report **immediately**?

- ☐ 1. respiratory rate of 12 breaths/min
- ☐ 2. patellar reflex of +2
- ☐ 3. blood pressure of 160/88 mm Hg
- ☐ 4. urinary output exceeding intake

19. As the nurse enters the room of a newly admitted primigravid client diagnosed with severe preeclampsia, the client begins to experience a seizure. Which action should the nurse take **first**?

- ☐ 1. Insert an airway to improve oxygenation.
- ☐ 2. Note the time when the seizure begins and ends.
- ☐ 3. Call for immediate assistance.
- ☐ 4. Turn the client to her left side.

20. After administering hydralazine 5 mg intravenously as prescribed for a primigravid client with severe preeclampsia at 39 weeks' gestation, the nurse should assess the client for:

- ☐ 1. tachycardia
- ☐ 2. bradypnea
- ☐ 3. polyuria
- ☐ 4. dysphagia

21. A primigravid client with severe preeclampsia exhibits hyperactive, very brisk patellar reflexes with two beats of ankle clonus present. How does the nurse document the patellar reflexes?

- ☐ 1. 1+

- ☐ 2. 2+
- ☐ 3. 3+
- ☐ 4. 4+

22. A 16-year-old unmarried primigravid client at 37 weeks' gestation with severe preeclampsia is in early active labor. The client's blood pressure is 164/110 mm Hg. Which finding would alert the nurse that the client may be about to experience a seizure?

- ☐ 1. decreased contraction intensity
- ☐ 2. decreased temperature
- ☐ 3. epigastric pain
- ☐ 4. hyporeflexia

23. Following an eclamptic seizure, the nurse should assess the client for which complication?

- ☐ 1. polyuria
- ☐ 2. facial flushing
- ☐ 3. hypotension
- ☐ 4. uterine contractions

24. A client at 36 weeks' gestation begins to exhibit signs of labor after an eclamptic seizure. The nurse should assess the client for:

- ☐ 1. abruptio placentae.
- ☐ 2. transverse lie.
- ☐ 3. placenta accreta.
- ☐ 4. uterine atony.

25. The nurse is reviewing the medical record of a multigravid client at 39 weeks' gestation with suspected HELLP syndrome. The nurse should notify the healthcare provider (HCP) about which test results?

- ☐ 1. platelets $200,000 \text{ mm}^3$ ($200 \times 10^9/\text{L}$)
- ☐ 2. lactate dehydrogenase (LDH) $> 200 \text{ U/L}$ ($3.34 \mu\text{kat/L}$)
- ☐ 3. uric acid 3 mg/dL ($178.4 \mu\text{mol/L}$)
- ☐ 4. aspartate aminotransferase (AST) 15 U/L ($0.25 \mu\text{kat/L}$)

The Pregnant Client with a Chronic Hypertensive Disorder

26. An obese 36-year-old multigravid client at 12 weeks' gestation has a history of chronic hypertension. She was treated with methyldopa before becoming pregnant. When counseling the client about diet during pregnancy, the nurse realizes that the client needs additional instruction when she makes which statement?

- ☐ 1. "I need to reduce my caloric intake to 1,200 cal/day."
- ☐ 2. "A regular diet is recommended during pregnancy."
- ☐ 3. "I should eat more frequent meals if I get heartburn."
- ☐ 4. "I need to consume more fluids and fiber each day."

27. After instructing a multigravid client at 10 weeks' gestation diagnosed with chronic hypertension about the need for frequent prenatal visits, the nurse determines that the instructions have been successful when the client makes which statement?

- ☐ 1. "I may develop hyperthyroidism because of my high blood pressure."
- ☐ 2. "I need close monitoring because I may have a small-for-gestational-age infant."
- ☐ 3. "It is possible that I will have excess amniotic fluid and may need a cesarean section."
- ☐ 4. "I may develop placenta accreta, so I need to keep my clinic appointments."

28. After reinforcing the danger signs to report with a gravida 2 client at 32 weeks' gestation with an elevated blood pressure, which client statements would demonstrate her understanding of when to call the primary healthcare provider's (HCP's) office? Select all that apply.

- ☐ 1. "if I feel dizzy when I get up quickly"
- ☐ 2. "if I see any bleeding, even if I have no pain"
- ☐ 3. "if I have a pounding headache that will not go away"
- ☐ 4. "if I notice the veins in my legs getting bigger"
- ☐ 5. "if the leg cramps at night are waking me up"
- ☐ 6. "if the baby seems to be more active than usual"

The Pregnant Client with Third-Trimester Bleeding

29. A client presents to the OB triage unit with no prenatal care and painless bright red vaginal bleeding. Which interventions are **most** indicated?

- ☐ 1. applying external fetal monitor and completing a physical assessment
- ☐ 2. applying external fetal monitor and performing a sterile vaginal exam
- ☐ 3. obtaining a fundal height physical assessment on the client
- ☐ 4. obtaining fundal height and a sterile vaginal exam

30. The nurse is caring for a 22-year-old G2, P2 client who has disseminated intravascular coagulation after delivering a dead fetus. Which finding is the **highest priority** to report to the healthcare provider (HCP)?

- ☐ 1. activated partial thromboplastin time (APTT) of 30 seconds
- ☐ 2. hemoglobin of 11.5 g/dL (115 g/L)
- ☐ 3. urinary output of 25 mL in the past hour
- ☐ 4. platelets at 149,000/mm³ ($149 \times 10^9/L$)

31. A 24-year-old client, G3, T1, P1, A1, L1 at 32 weeks' gestation, is admitted to the hospital because of vaginal bleeding. After reviewing the client's history, which factor might lead the nurse to suspect abruptio placentae?

- ☐ 1. several hypotensive episodes
- ☐ 2. previous low transverse cesarean birth
- ☐ 3. one induced abortion
- ☐ 4. history of cocaine use

32. When caring for a multigravid client admitted to the hospital with vaginal bleeding at 38 weeks' gestation, which therapeutic agent would the nurse anticipate administering intravenously if the client develops disseminated intravascular coagulation (DIC)?

- ☐ 1. Ringer's lactate solution
- ☐ 2. fresh frozen platelets
- ☐ 3. 5% dextrose solution
- ☐ 4. warfarin

33. When assessing a 34-year-old multigravid client at 34 weeks' gestation

experiencing moderate vaginal bleeding, which symptom would **most** likely alert the nurse that placenta previa is present?

- ☐ 1. painless vaginal bleeding
- ☐ 2. uterine tetany
- ☐ 3. intermittent pain with spotting
- ☐ 4. dull lower back pain

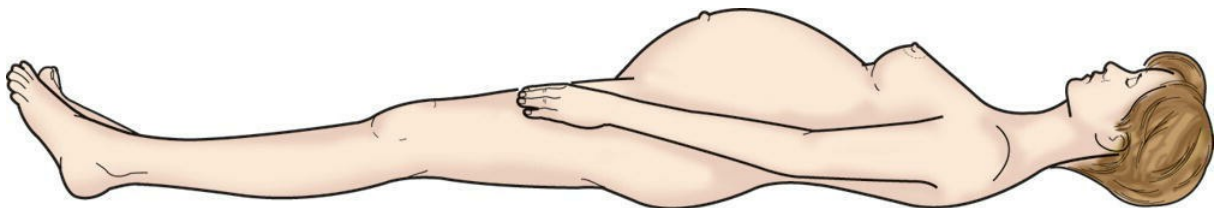

34. The primary healthcare provider (HCP) prescribes whole blood replacement for a multigravid client with abruptio placentae. Before administering the intravenous blood product, the nurse should **first**:

- ☐ 1. validate client information and the blood product with another nurse.
- ☐ 2. check the vital signs before transfusing over 5 to 6 hours.
- ☐ 3. ask the client if she has ever had any allergies.
- ☐ 4. administer 100 mL of 5% dextrose solution intravenously.

35. Following a cesarean birth for abruptio placentae, a multigravid client tells the nurse, “I feel like such a failure. None of my other childbirths were like this.” Which factor is **most** important for the nurse to consider when responding to the client?

- ☐ 1. The client will most likely have postpartum blues.
- ☐ 2. Maternal-infant bonding is likely to be difficult.
- ☐ 3. The client’s feeling of grief is a normal reaction.
- ☐ 4. This type of birth was necessary to save the client’s life.

36. A client has received epidural anesthesia to control pain during a vaginal birth. Place an X over the highest point on the body locating the level of anesthesia expected for a vaginal birth.

37. Which action should the nurse take **first** when admitting a multigravid client at 36 weeks’ gestation with a probable diagnosis of abruptio placentae?

- ☐ 1. Prepare the client for a vaginal examination.

- ☐ 2. Obtain a brief history from the client.
- ☐ 3. Insert a large-gauge intravenous catheter.
- ☐ 4. Prepare the client for an ultrasound scan.

The Pregnant Client with Preterm Labor

38. The healthcare provider (HCP) has determined that a preterm labor client at 34 weeks' gestation has no fetal fibronectin present. Based on this finding, the nurse would anticipate that within the next week:

- ☐ 1. the client will develop preeclampsia.
- ☐ 2. the fetus will develop mature lungs.
- ☐ 3. the client will not develop preterm labor.
- ☐ 4. the fetus will not develop gestational diabetes.

39. A nurse is discussing preterm labor in a prenatal class. After class, a client asks the nurse to identify again the nursing strategies to prevent preterm labor. The client needs further instruction when she makes which statement?

- ☐ 1. "I need to stay hydrated all the time."
- ☐ 2. "Even dental infections can lead to preterm labor."
- ☐ 3. "I should include frequent rest breaks if I travel."
- ☐ 4. "Cutting back on my smoking will not help my baby."

40. A multigravid client at 34 weeks' gestation is being treated with indomethacin to halt preterm labor. If the client gives birth to a preterm infant, the nurse should notify the nursery personnel about this therapy because of the possibility for which complication?

- ☐ 1. pulmonary hypertension
- ☐ 2. respiratory distress syndrome (RDS)
- ☐ 3. hyperbilirubinemia
- ☐ 4. cardiomyopathy

41. Which statement by the client indicates an understanding of the teaching regarding the use of corticosteroids during preterm labor?

- ☐ 1. "I will be taking corticosteroids until my baby's due date so that he or she will have the best chance of doing well."

- ☐ 2. “The corticosteroids may help my baby’s lungs mature.”
- ☐ 3. “The goal of the corticosteroids is to stop contractions and help me get to my due date.”
- ☐ 4. “If I take corticosteroids, my baby will not have to spend any time in the neonatal intensive care unit when he or she is born.”

42. In which maternal locations would the nurse place the ultrasound transducer of the external electronic fetal heart rate monitor if a fetus at 34 weeks’ gestation is in the left occipitoanterior (LOA) position?

- ☐ 1. near the symphysis pubis
- ☐ 2. two inches (5.1 cm) above the umbilicus
- ☐ 3. below the umbilicus on the left side
- ☐ 4. at the level of the umbilicus

43. The primary healthcare provider (HCP) prescribes betamethasone for a 34-year-old multigravid client at 32 weeks’ gestation who is experiencing preterm labor. Previously, the client has experienced one infant death due to preterm birth at 28 weeks’ gestation. The nurse explains that this drug is given for which reason?

- ☐ 1. to enhance fetal lung maturity
- ☐ 2. to counter the effects of tocolytic therapy
- ☐ 3. to treat chorioamnionitis
- ☐ 4. to decrease neonatal production of surfactant

44. When preparing a multigravid client at 34 weeks’ gestation experiencing preterm labor for the shake test performed on amniotic fluid, the nurse would instruct the client that this test is done to evaluate the maturity of which fetal systems?

- ☐ 1. urinary
- ☐ 2. gastrointestinal
- ☐ 3. cardiovascular
- ☐ 4. pulmonary

The Pregnant Client with Premature Rupture of the Membranes

45. The nurse is planning care for a multigravid client hospitalized at 36 weeks' gestation with confirmed rupture of membranes and no evidence of labor. What prescription would the nurse anticipate from the primary healthcare provider (HCP)?

- ☐ 1. frequent assessments of cervical dilation
- ☐ 2. intravenous oxytocin administration
- ☐ 3. vaginal cultures for *Neisseria gonorrhoeae*
- ☐ 4. sonogram for amniotic fluid volume index

46. A multigravid client at 34 weeks' gestation visits the hospital because she suspects that her water has broken. After testing the leaking fluid with nitrazine paper, the nurse confirms that the client's membranes have ruptured when the paper turns which color?

- ☐ 1. yellow
- ☐ 2. white
- ☐ 3. blue
- ☐ 4. red

47. A primigravid client at 30 weeks' gestation has been admitted to the hospital with premature rupture of the membranes without contractions. Her cervix is 2 cm dilated and 50% effaced. The nurse should next assess the client's:

- ☐ 1. red blood cell count.
- ☐ 2. degree of discomfort.
- ☐ 3. urinary output.
- ☐ 4. temperature.

48. A multigravid client at 34 weeks' gestation with premature rupture of the membranes tests positive for group B streptococcus. The client is having contractions every 4 to 6 minutes. Her vital signs are as follows: blood pressure, 120/80 mm Hg; temperature, 100°F (37.8°C); pulse, 100 bpm; respirations, 18 breaths/min. Which medication would the nurse expect the primary healthcare provider (HCP) to prescribe?

- ☐ 1. intravenous penicillin
- ☐ 2. intravenous gentamicin sulfate

- ☐ 3. intramuscular betamethasone
- ☐ 4. intramuscular cefaclor

49. A primigravid client at 36 weeks' gestation with premature rupture of the membranes is to be discharged home on bed rest with follow-up by the nurse. After instruction about care while at home, which client statement indicates effective teaching?

- ☐ 1. "It is permissible to douche if the fluid irritates my vaginal area."
- ☐ 2. "I can take either a tub bath or a shower when I feel like it."
- ☐ 3. "I should limit my fluid intake to less than 1 quart (0.95 L) daily."
- ☐ 4. "I should contact the healthcare provider if my temperature is 100.4°F (38°C) or higher."

50. A primigravid client at 34 weeks' gestation is experiencing contractions every 3 to 4 minutes lasting for 35 seconds. Her cervix is 2 cm dilated and 50% effaced. While the nurse is assessing the client's vital signs, the client says, "I think my bag of water just broke." Which intervention would the nurse do **first**?

- ☐ 1. Check the status of the fetal heart rate.
- ☐ 2. Turn the client to her right side.
- ☐ 3. Test the leaking fluid with nitrazine paper.
- ☐ 4. Perform a sterile vaginal examination.

The Pregnant Client with Diabetes Mellitus

51. The antenatal clinic nurse is educating a client with gestational diabetes soon after diagnosis. Evaluation for this client session will include which outcome? Select all that apply.

- ☐ 1. The client states the need to maintain blood glucose levels between 70 and 110 mg/dL (3.9 to 6.2 mmol/L).
- ☐ 2. The client describes her planned walking program while pregnant.
- ☐ 3. The client will strive to maintain a hemoglobin A1C of less than 6%.
- ☐ 4. The client verbalizes the need to maintain a dietary intake of less than 1,500 cal/day to prevent hyperglycemia.
- ☐ 5. The client will continue taking her prenatal vitamins, iron, and folic

acid.

52. A 27-year-old primigravid client with insulin-dependent diabetes at 34 weeks' gestation undergoes a nonstress test, the results of which are documented as reactive. What should the nurse tell the client that the test results indicate?

- ☐ 1. A contraction stress test is necessary.
- ☐ 2. The nonstress test should be repeated.
- ☐ 3. Chorionic villus sampling is necessary.
- ☐ 4. There is evidence of fetal well-being.

53. A primigravid client with insulin-dependent diabetes tells the nurse that the contraction stress test performed earlier in the day was suspicious. The nurse interprets this test result as showing which fetal heart rate pattern?

- ☐ 1. frequent late decelerations
- ☐ 2. decreased fetal movement
- ☐ 3. inconsistent late decelerations
- ☐ 4. lack of fetal movement

54. Which statement about a fetal biophysical profile would be incorporated into the teaching plan for a primigravid client with insulin-dependent diabetes?

- ☐ 1. It determines fetal lung maturity.
- ☐ 2. It is noninvasive using real-time ultrasound.
- ☐ 3. It will correlate with the newborn's Apgar score.
- ☐ 4. It requires the client to have an empty bladder.

55. A 30-year-old multigravid client at 8 weeks' gestation has a history of insulin-dependent diabetes since age 20. When explaining about the importance of blood glucose control during pregnancy, the nurse should tell the client that which will occur regarding the client's insulin needs during the first trimester?

- ☐ 1. They will increase.
- ☐ 2. They will decrease.
- ☐ 3. They will remain constant.
- ☐ 4. They will be unpredictable.

56. The nurse explains the complications of pregnancy that occur with diabetes to a primigravid client at 10 weeks' gestation who has a 5-year history of insulin-dependent diabetes. Which complication, if stated by the client, indicates the need for additional teaching?

- ☐ 1. *Candida albicans* infection
- ☐ 2. twin-to-twin transfusion
- ☐ 3. polyhydramnios
- ☐ 4. preeclampsia

57. When developing a teaching plan for a primigravid client with insulin-dependent diabetes about monitoring blood glucose control and insulin dosages at home, what would the nurse expect to include as a desired target range for blood glucose levels?

- ☐ 1. 40 to 60 mg/dL (2.2 to 3.3 mmol/L) between 1,400 and 1,600 hours
- ☐ 2. 70 to 100 mg/dL (3.3 to 5.6 mmol/L) before meals and bedtime snacks
- ☐ 3. 110 to 140 mg/dL (6.2 to 7.8 mmol/L) before meals and bedtime snacks
- ☐ 4. 140 to 160 mg/dL (7.8 to 8.9 mmol/L) 1 hour after meals

58. When teaching a primigravid client with diabetes about common causes of hyperglycemia during pregnancy, which information would the nurse include?

- ☐ 1. fetal macrosomia
- ☐ 2. decreased fetal insulin
- ☐ 3. maternal infection
- ☐ 4. gestational hypertension

59. After teaching a diabetic primigravida about symptoms of hyperglycemia and hypoglycemia, the nurse determines that the client understands the instruction when she says that hyperglycemia may be manifested by which symptom?

- ☐ 1. dehydration
- ☐ 2. pallor
- ☐ 3. sweating
- ☐ 4. nervousness

60. At 38 weeks' gestation, a primigravid client with poorly controlled diabetes and severe preeclampsia is admitted for a cesarean birth. The nurse explains to the client that birth helps to prevent which complication?

- ☐ 1. Neonatal hyperbilirubinemia
- ☐ 2. Congenital anomalies
- ☐ 3. Perinatal asphyxia
- ☐ 4. Stillbirth

61. A primigravid client with diabetes at 39 weeks' gestation is seen in the high-risk clinic. The primary healthcare provider (HCP) estimates that the fetus weighs at least 10 lb (4,500 g). The client asks, "What causes the baby to be so large?" The nurse's response is based on the understanding that fetal macrosomia is most related to which factor?

- ☐ 1. family history of large infants
- ☐ 2. fetal anomalies
- ☐ 3. maternal hyperglycemia
- ☐ 4. maternal hypertension

62. With plans to breast-feed her neonate, a pregnant client with insulin-dependent diabetes asks the nurse about insulin needs during the postpartum period. Which statement about postpartal insulin requirements for breast-feeding mothers should the nurse include in the explanation?

- ☐ 1. They fall significantly in the immediate postpartum period.
- ☐ 2. They remain the same as during the labor process.
- ☐ 3. They usually increase in the immediate postpartum period.
- ☐ 4. They need constant adjustment during the first 24 hours.

The Pregnant Client with Heart Disease

63. After instruction of a primigravid client at 8 weeks' gestation diagnosed with class I heart disease about self-care during pregnancy, which client statement would indicate the need for additional teaching?

- ☐ 1. "I should avoid being near people who have a cold."
- ☐ 2. "I may be given antibiotics during my pregnancy."
- ☐ 3. "I should reduce my intake of protein in my diet."

- ☐ 4. "I should limit my salt intake at meals."

64. While caring for a primigravid client with class II heart disease at 28 weeks' gestation, the nurse would instruct the client to contact her primary healthcare provider (HCP) immediately if the client experiences which symptom?

- ☐ 1. mild ankle edema
- ☐ 2. emotional stress on the job
- ☐ 3. weight gain of 1 lb (0.45 kg) in 1 week
- ☐ 4. dyspnea at rest

65. When developing the collaborative plan of care with the healthcare provider (HCP) for a multigravid client at 10 weeks' gestation with a history of cardiac disease who was being treated with digitalis therapy before this pregnancy, the nurse should instruct the client about which modification regarding the client's drug therapy regimen?

- ☐ 1. need for an increased dosage
- ☐ 2. continuation of the same dosage
- ☐ 3. switching to a different medication
- ☐ 4. addition of a diuretic to the regimen

66. Which anticoagulants would the nurse expect to administer when caring for a primigravid client at 12 weeks' gestation who has class II cardiac disease due to mitral valve stenosis?

- ☐ 1. heparin
- ☐ 2. warfarin
- ☐ 3. enoxaparin
- ☐ 4. ardeparin

67. A primigravid client with class II heart disease who is visiting the clinic at 8 weeks' gestation tells the nurse that she has been maintaining a low-sodium, 1,800-cal diet. Which instruction should the nurse give the client?

- ☐ 1. Avoid folic acid supplements to prevent megaloblastic anemia.
- ☐ 2. Severely restrict sodium intake throughout the pregnancy.
- ☐ 3. Take iron supplements with milk to enhance absorption.

- ☐ 4. Increase caloric intake to 2,200 calories daily to promote fetal growth.

The Client with an Ectopic Pregnancy

68. On arrival at the emergency department, a client tells the nurse that she suspects that she may be pregnant but has been having a small amount of bleeding and has severe pain in the lower abdomen. The client's blood pressure is 70/50 mm Hg, and her pulse rate is 120 bpm. The nurse notifies the primary healthcare provider (HCP) immediately because of the possibility of:

- ☐ 1. ectopic pregnancy.
- ☐ 2. abruptio placentae.
- ☐ 3. gestational trophoblastic disease.
- ☐ 4. complete abortion.

69. The nurse is assessing a multigravid client at 12 weeks' gestation who has been admitted to the emergency department with sharp right-sided abdominal pain and vaginal spotting. Which information should the nurse obtain about the client's history? Select all that apply.

- ☐ 1. history of sexually transmitted infections
- ☐ 2. number of sexual partners
- ☐ 3. last menstrual period
- ☐ 4. cesarean section
- ☐ 5. contraceptive use

70. Before surgery to remove an ectopic pregnancy and the fallopian tube, which sign or symptom would alert the nurse to the possibility of tubal rupture?

- ☐ 1. amount of vaginal bleeding and discharge
- ☐ 2. profuse sweating
- ☐ 3. slow, bounding pulse rate of 80 bpm
- ☐ 4. marked abdominal edema

71. A multigravid client diagnosed with a probable ruptured ectopic pregnancy is scheduled for emergency surgery. In addition to monitoring the client's blood pressure before surgery, which factor is **most** important for the

nurse to assess?

- ☐ 1. uterine cramping
- ☐ 2. abdominal distention
- ☐ 3. hemoglobin and hematocrit
- ☐ 4. pulse rate

72. A 36-year-old multigravid client is admitted to the hospital with possible ruptured ectopic pregnancy. When obtaining the client's history, which finding would be **most** important to identify as a predisposing factor?

- ☐ 1. urinary tract infection
- ☐ 2. marijuana use during pregnancy
- ☐ 3. episodes of pelvic inflammatory disease
- ☐ 4. use of estrogen-progestin contraceptives

73. A multigravid client is admitted to the hospital with a diagnosis of ectopic pregnancy. The nurse anticipates that, because the client's fallopian tube has not yet ruptured, which medication may be prescribed?

- ☐ 1. progestin contraceptives
- ☐ 2. medroxyprogesterone
- ☐ 3. methotrexate
- ☐ 4. dyphylline

The Pregnant Client with Hyperemesis Gravidarum

74. After instruction of a primigravid client at 8 weeks' gestation about measures to overcome early morning nausea and vomiting, which client statement indicates the need for additional teaching?

- ☐ 1. "I will eat dry crackers or toast before arising in the morning."
- ☐ 2. "I will drink adequate fluids separate from my meals or snacks."
- ☐ 3. "I will eat two large meals daily with frequent protein snacks."
- ☐ 4. "I will snack on a small amount of carbohydrates throughout the day."

75. A multigravid client thought to be at 14 weeks' gestation reports that she is experiencing such severe morning sickness that she "has not been able to keep anything down for a week." The nurse should assess for signs and symptoms of which condition?

- ☐ 1. hypercalcemia
- ☐ 2. hypobilirubinemia
- ☐ 3. hypokalemia
- ☐ 4. hyperglycemia

76. A multigravid client is admitted at 16 weeks' gestation with a diagnosis of hyperemesis gravidarum. The nurse should explain to the client that hyperemesis gravidarum is thought to be related to high levels of which hormone?

- ☐ 1. progesterone
- ☐ 2. estrogen
- ☐ 3. somatotropin
- ☐ 4. aldosterone

77. The primary healthcare provider (HCP) prescribes 1,000 mL of Ringer's lactate intravenously over an 8-hour period for a 29-year-old primigravid client at 16 weeks' gestation with hyperemesis. The drip factor is 12 gtts/mL. The nurse should administer the IV infusion at how many drops per minute? Record your answer using one decimal place.

_____ gtts/min.

78. In caring for a pregnant client with hyperemesis gravidarum, which is the **priority** nursing intervention?

- ☐ 1. providing adequate sleep for the client
- ☐ 2. correction of fluid-electrolyte imbalance
- ☐ 3. reviewing dietary choices and food intake
- ☐ 4. acetaminophen suppositories

The Client with a Gestational Trophoblastic Disease

79. A client at 15 weeks' gestation presents at the obstetrical triage unit with dark brown vaginal bleeding and continuous nausea and vomiting. Her blood pressure is 142/98 mm Hg and fundal height is 19 cm. Which prescription is **most** important for the nurse to request from the primary care provider?

- ☐ 1. a transfer to the antenatal unit

- ☐ 2. NPO status for 24 hours
- ☐ 3. intravenous magnesium sulfate
- ☐ 4. stat ultrasound

80. A 38-year-old client at about 14 weeks' gestation is admitted to the hospital with a diagnosis of complete hydatidiform mole. Soon after admission, the nurse would assess the client for which signs and symptoms?

- ☐ 1. gestational hypertension
- ☐ 2. gestational diabetes
- ☐ 3. hypothyroidism
- ☐ 4. polycythemia

81. After a dilatation and curettage (D&C) to evacuate a molar pregnancy, assessing the client for which signs and symptoms would be **most** important?

- ☐ 1. urinary tract infection
- ☐ 2. hemorrhage
- ☐ 3. abdominal distention
- ☐ 4. chorioamnionitis

82. When preparing a multigravid client who has undergone evacuation of a hydatidiform mole for discharge, the nurse explains the need for follow-up care. The nurse determines that the client understands the instruction when she says that she is at risk for developing which problem?

- ☐ 1. ectopic pregnancy
- ☐ 2. choriocarcinoma
- ☐ 3. multifetal pregnancies
- ☐ 4. infertility

83. After suction and evacuation of a complete hydatidiform mole, the 28-year-old multigravid client asks the nurse when she can become pregnant again. The nurse would advise the client not to become pregnant again for at least how long?

- ☐ 1. 6 months
- ☐ 2. 12 months
- ☐ 3. 18 months
- ☐ 4. 24 months

84. A woman is diagnosed with complete molar pregnancy. The nurse understands that the woman requires more teaching when she makes which statement?

- ☐ 1. “I need to make follow-up appointments to have my hormone levels checked.”
- ☐ 2. “I know the placenta caused problems, and my baby died in my uterus.”
- ☐ 3. “I plan to get pregnant again next year.”
- ☐ 4. “I understand I may develop a serious type of cancer.”

The Pregnant Client with Miscellaneous Complications

85. The nurse is working with four clients on the obstetrical unit. Which client will be the highest **priority** for a cesarean section?

- ☐ 1. client at 40 weeks’ gestation whose fetus weighs 8 lb (3,630 g) by ultrasound estimate
- ☐ 2. client at 37 weeks’ gestation with fetus in ROP position
- ☐ 3. client at 32 weeks’ gestation with fetus in breech position
- ☐ 4. client at 38 weeks’ gestation with active herpes lesions

86. The nurse notices that a client who has just given birth is short of breath, is ashen in color, and begins to cough. She becomes limp on the birthing table. At last assessment ½ hour ago, her temperature was 98°F (36.7°C), pulse was 78 beats/min, and respirations were 16 breaths/min. Determine the nursing actions in the order they should occur. All options must be used.

1. Open airway using head tilt-chin lift.

2. Ask staff to activate emergency response system.

3. Establish unresponsiveness.

4. Give two breaths.

5. Begin compressions.

87. A client in sickle cell crisis has been hospitalized during her pregnancy. After giving discharge instructions, the nurse determines the client needs further teaching when she makes which statement?

- ☐ 1. "I will need more frequent appointments during the remainder of the pregnancy."
- ☐ 2. "Signs of any type of infection must be reported immediately."
- ☐ 3. "At the earliest signs of a crisis, I need to seek treatment."
- ☐ 4. "I will need to take an iron supplement even if my laboratory values are normal."

88. A laboring client at -2 station has a spontaneous rupture of the membranes, and a cord immediately protrudes from the vagina. The nurse should **first**:

- ☐ 1. place gentle pressure upward on the fetal head.
- ☐ 2. place the cord back into the vagina to keep it moist.
- ☐ 3. begin oxygen by face mask at 8 to 10 L/min.
- ☐ 4. turn the client on her left side.

89. A client has just had a cesarean section for a prolapsed cord. In reviewing the client's history, which factors place a client at risk for cord prolapse? Select all that apply.

- ☐ 1. negative 2 station
- ☐ 2. low-birth-weight infant

- ☐ 3. rupture of membranes
- ☐ 4. breech presentation
- ☐ 5. prior abortion
- ☐ 6. low-lying placenta

90. A woman who has given birth to a healthy neonate is being discharged. As part of discharge teaching, the nurse should instruct the client to observe vaginal discharge for postpartum hemorrhage and notify the healthcare provider (HCP) about:

- ☐ 1. bleeding that becomes lighter each day.
- ☐ 2. clots the size of grapes.
- ☐ 3. saturating a pad in an hour.
- ☐ 4. lochia that lasts longer than 1 week.

91. A woman who is Rh negative has given birth to an Rh-positive infant. The nurse explains to the client that she will receive Rho (D) immune globulin (RhoGAM). The nurse determines that the client understands the purpose of RhoGAM when she states:

- ☐ 1. "RhoGAM will protect my next baby if it is Rh negative."
- ☐ 2. "RhoGAM will prevent antibody formation in my blood."
- ☐ 3. "RhoGAM will be given to prevent antigen formation in my baby's blood."
- ☐ 4. "RhoGAM will be used to prevent bleeding in my newborn."

92. A client at 4 weeks postpartum tells the nurse that she cannot cope any longer and is overwhelmed by her newborn. The baby has old formula on her clothes and under her neck. The mother does not remember when she last bathed the baby and states she does not want to care for the infant. The nurse should encourage the client and her husband to call their healthcare provider (HCP) because the mother should be evaluated further for:

- ☐ 1. postpartum blues
- ☐ 2. postpartum depression
- ☐ 3. poor bonding
- ☐ 4. infant abuse

93. The nurse and an unlicensed assistive personnel (UAP) are caring for

clients in a birthing center. Which tasks should the nurse delegate to the UAP? Select all that apply.

- ☐ 1. removing a Foley catheter from a postpartum client
- ☐ 2. assisting an active labor client with breathing and relaxation
- ☐ 3. ambulating a postcesarean client to the bathroom
- ☐ 4. calculating hourly IV totals for a preterm labor client
- ☐ 5. intake and output catheterization for culture and sensitivity
- ☐ 6. calling a report of normal findings to the healthcare provider (HCP)

Managing Care, Quality, and Safety for Pregnant Clients

94. Several pregnant clients are waiting to be seen in the triage area of the obstetrical unit. Which client should the nurse see **first**?

- ☐ 1. a client at 13 weeks' gestation who is experiencing nausea and vomiting three times a day with +1 ketones in her urine
- ☐ 2. a client at 37 weeks' gestation who is an insulin-dependent diabetic and experiencing 3 to 4 fetal movements per day
- ☐ 3. a client at 32 weeks' gestation who has preeclampsia and +3 proteinuria and who is returning for evaluation of epigastric pain
- ☐ 4. a client at 17 weeks' gestation who is not feeling fetal movement at this point in her pregnancy

95. The nurse is planning care for a group of pregnant clients. Which client should be referred to a healthcare provider (HCP) immediately?

- ☐ 1. a woman who is at 10 weeks' gestation, is having nausea and vomiting, and has +1 ketones in her urine
- ☐ 2. a woman who is at 37 weeks' gestation and has insulin-dependent diabetes experiencing two to three hyperglycemic episodes weekly
- ☐ 3. a woman at 32 weeks' gestation who is preeclamptic with +3 proteinuria
- ☐ 4. a woman at 15 weeks' gestation who reports she has not felt fetal movement

96. A client with gestational hypertension is to receive magnesium sulfate to run at 3 g/h with normal saline to maintain the total IV rate at 125 mL/h.

The nurse giving the end-of-shift report stated that the client's blood pressures have been elevated during the night. The oncoming nurse checked the client and found magnesium sulfate running at 2 g/h. Identify the nursing actions to be taken from first to last. All options must be used.

1. Notify the primary healthcare provider (HCP) of the incident.

2. Assess the client's current status.

3. Correct the IV rates.

4. Initiate an incident report.

97. As the nurse enters the room of a newly admitted primigravid client diagnosed with severe preeclampsia, the client begins to experience a seizure. The nurse should do which in order of **priority** from first to last? All options must be used.

1. Call for immediate assistance.

2. Turn the client to her side.

3. Assess for ruptured membranes.

4. Maintain airway.

98. The nurse is receiving shift report on four clients on an antenatal unit. The four clients are (1) a 35-week-gestation mother with severe preeclampsia started on a maintenance dose of magnesium sulfate 1 hour ago, (2) a 30-week-gestation client with preterm labor on an oral tocolytic and having no contractions in 6 hours, (3) a hyperemesis client with emesis four times in the past 12 hours, and (4) a 33-week-gestation client with placenta previa who began to feel pelvic pressure during change of shift report. Which action should the nurse take **first**?

- ☐ 1. Evaluate the client with preeclampsia for maternal and fetal tolerance of magnesium sulfate and the labor pattern.
- ☐ 2. Assess the client with preterm labor for tolerance of tocolytics and the labor pattern.
- ☐ 3. Assess the client with hyperemesis for nausea, further emesis, or dehydration.
- ☐ 4. Evaluate the client with placenta previa without an exam.

99. Which client findings require the nurse's attention **first**?

- ☐ 1. a gravida 2, para 1 at 39 weeks' gestation with spontaneous rupture of membranes 1 hour ago but no contractions
- ☐ 2. a gravida 3, para 2 at 30 weeks' gestation with nausea, vomiting, and epigastric pain
- ☐ 3. a gravida 5, para 1 at 37 weeks' gestation with pink vaginal discharge and abdominal cramping
- ☐ 4. a gravida 1, para 0 at 39 weeks' gestation with bruises on the arms and abdomen at various stages of healing

Answers, Rationales, and Test-Taking Strategies

The answers and rationales for each question follow below, along with keys () to the client need (CN) and cognitive level (CL) for each question. In addition, you will also see a glossary icon () highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 12–23 and pages 35–36 in Part 1 of this book.

The Pregnant Client with Preeclampsia or Eclampsia

1. 50 mL

$$\frac{500 \text{ mL}}{20 \text{ g}} \times \frac{2 \text{ g}}{\text{h}} = \frac{\overset{50}{\cancel{1,000}} \text{ g/mL}}{\underset{1}{\cancel{20}} \text{ g/h}} = \frac{500 \text{ mL}}{1 \text{ h}}$$

 CN: Pharmacological and parenteral therapies; CL: Apply

2. 3. The two major defining characteristics of preeclampsia are blood pressure elevation of 140/90 mm Hg or greater and proteinuria. Because the client's blood pressure meets the gestational hypertension criteria, the next nursing responsibility is to determine if she has protein in her urine. If she does not, then she may be having transient hypertension. The peripheral edema is within normal limits for someone at this gestational age, particularly because it is in the lower extremities. While the preeclamptic client may have significant edema in the face and hands, edema can be caused by other factors and is not part of the diagnostic criteria. Headaches are significant in pregnancy-induced hypertension but may have other etiologies. The client's blood glucose level has no bearing on a preeclampsia diagnosis.

 CN: Physiological adaptation; CL: Analyze

3. 4. The fetus is considered well if it moves more often than three times in

1 hour. Daily fetal movement counting is part of all high-risk assessments and is a noninvasive, inexpensive method of monitoring fetal well-being. The **HCP** should be notified if there is a gradual slowing over time of fetal activity, if each day it takes longer for the fetus to move a minimum of 10 times, or if the fetus stops moving for 12 hours or longer.

CN: Reduction of risk potential; CL: Evaluate

4. 3. The central nervous system (CNS) functioning and freedom from injury is a priority in maintaining well-being of the maternal-fetal unit. If the mother suffers CNS damage related to hypertension or stroke, oxygenation status is compromised, and the well-being of both mother and infant are at risk. Continuous fetal monitoring is an assessment strategy for the infant only and would be of secondary importance to maternal CNS assessment because maternal oxygenation will dictate fetal oxygenation and well-being. In preeclampsia, frequent assessment of maternal reflexes, clonus, visual disturbances, and headache give clear evidence of the condition of the maternal CNS system. Monitoring the liver studies does give an indication of the status of the maternal system, but the less invasive and highly correlated condition of the maternal CNS system in assessing reflexes, maternal headache, visual disturbances, and clonus is the highest priority. Psychosocial care is a priority and can be accomplished in ways other than having the family remain at the bedside.

CN: Safety and infection control; CL: Synthesize

5. 3. Clients with increased risk for preeclampsia include primigravid clients younger than 20 years or older than 40 years, clients with 5 or more pregnancies, women of color, women with multifetal pregnancies, women with diabetes or heart disease, and women with hydramnios. A total weight gain of 20 lb (9.1 kg) at 32 weeks' gestation with a 1-lb (0.45-kg) weight gain in the last 2 weeks is within normal limits. Short stature is not associated with the development of preeclampsia. A trace amount of protein in the urine is common during pregnancy. However, protein amounts of 1+ or more may be a symptom of pregnancy-induced hypertension.

CN: Reduction of risk potential; CL: Synthesize

6. 1. Congenital anomalies such as hydrocephalus are not associated with

preeclampsia. Conditions such as stillbirth, prematurity, abruptio placentae, intrauterine growth restriction, and poor placental perfusion are associated with preeclampsia. Abruptio placentae occurs because of severe vasoconstriction. Intrauterine growth restriction is possible owing to poor placental perfusion. Poor placental perfusion results from increased vasoconstriction.

CN: Physiological adaptation; CL: Evaluate

7. 1,3,4. The nurse must be alert for any signs and symptoms of superimposed preeclampsia in women with gestational hypertension. Dull headache, blurred vision, and protein in urine are all classic signs of preeclampsia in pregnancy and must be reported to the primary care provider immediately. Edema in lower extremities is not a sign of preeclampsia in pregnancy as it is seen in uncomplicated pregnancy. Fundal height of 28 cm is an expected finding.

CN: Management of care; CL: Analyze

8. 3. For clients with mild preeclampsia, a regular diet with ample protein and calories is recommended. If the client experiences constipation, she should increase the fiber in her diet, such as by eating raw fruits and vegetables, and increase fluid intake. A high-residue diet is not a nutritional need in preeclampsia. Sodium and fluid intake should not be restricted or increased. A high-protein diet is unnecessary.

CN: Basic care and comfort; CL: Apply

9. 3. The nurse must be alert to signs of magnesium sulfate toxicity that include loss of deep tendon reflexes, which is often the first sign (patellar-tendon response is the most common reflex tested); urinary output decreases (should have at least 30 mL/h); respirations decrease (12 respirations/min is low and could be developing respiratory distress). First action would be to stop magnesium sulfate infusion and notify the **HCP**. The Foley catheter tubing maybe kinked; however, looking at all findings would indicate the woman is experiencing magnesium sulfate toxicity. It is not a priority to obtain a urine sample. Documentation is extremely important to complete; however, the nurse must intervene by stopping the magnesium sulfate and notifying the primary care provider. Increasing fluid intake at this point is not

appropriate with a woman who has magnesium sulfate toxicity. Intake and output should be ongoing for a client on intravenous fluids and magnesium sulfate and a diagnosis of preeclampsia.

CN: Pharmacological and parenteral therapies; CL: Apply

10. 2. A client with preeclampsia and a continuous headache for 2 days should be seen by a **healthcare provider (HCP)**  immediately. Continuous headache, drowsiness, and mental confusion indicate poor cerebral perfusion and are symptoms of severe preeclampsia. Immediate care is recommended because these symptoms may lead to eclampsia or seizures if left untreated. Advising the client to take two acetaminophen tablets would be inappropriate and may lead to further complications if the client is not evaluated and treated. Although the application of cool compresses may ease the pain temporarily, this would delay treatment. Treatment for nausea may be indicated but only after the primary care primary provider has seen the client and determined if the preeclampsia requires further treatment.

CN: Reduction of risk potential; CL: Synthesize

11. 4. The client with severe preeclampsia may develop eclampsia, which is characterized by seizures. The client needs a darkened, quiet room and side rails with thick padding. This helps decrease the potential for injury should a seizure occur. Airways, a suction machine, and oxygen also should be available. If the client is to undergo induction of labor, oxytocin infusion solution can be obtained at a later time. Tongue blades are not necessary. However, the emergency cart should be placed nearby in case the client experiences a seizure. The ultrasound machine may be used at a later point to provide information about the fetus. In many hospitals, the client with severe preeclampsia is admitted to the labor area, where she and the fetus can be closely monitored. The safety of the client and her fetus is the priority.

CN: Physiological adaptation; CL: Apply

12. 1. Although the client is being admitted, the first response would be to attempt to lower BP by putting the client in left lateral position. The other interventions may be appropriate later, but left lateral position would be the priority.

 CN: Management of care; CL: Analyze

13. 3. The client receiving magnesium sulfate intravenously is at risk for possible toxicity. The antidote for magnesium sulfate toxicity is calcium gluconate, which should be readily available at the client's bedside. Diazepam is used to treat anxiety, and usually it is not given to pregnant women. Hydralazine would be used to treat hypertension, and phenytoin would be used to treat seizures.

 CN: Pharmacological and parenteral therapies; CL: Apply

14. 1. Typical signs of hypermagnesemia include decreased deep tendon reflexes, sweating or a flushing of the skin, oliguria, decreased respirations, and lethargy progressing to coma as the toxicity increases. The nurse should check the client's patellar, biceps, and radial reflexes regularly during magnesium sulfate therapy. Cool skin temperature may result from peripheral vasodilation, but the opposite—flushing and sweating—are usually seen. A rapid pulse rate commonly occurs in hypomagnesemia. Tingling in the toes may suggest hypocalcemia, not hypermagnesemia.

 CN: Physiological adaptation; CL: Analyze

15. 2,3,4. Headaches could be a sign of preeclampsia/eclampsia in pregnancy. The client should be assessed for headache, vision changes, epigastric pain, hyper reflexes, and the presence of clonus. Her fetus should be assessed using a nonstress test. An ultrasound done in this pregnancy does not give information to assess the presence of preeclampsia/eclampsia.

 CN: Management of care; CL: Analyze

16. 4. The highest priority for a client with severe preeclampsia is to prevent seizures, thereby minimizing the possibility of adverse effects on the mother and fetus, and then to facilitate safe birth. Efforts to decrease edema, reduce blood pressure, increase urine output, limit kidney damage, and maintain sedation are desirable but are not as important as preventing seizures. It would take several days or weeks for the edema to be decreased. Sedation and decreased reflex excitability can occur with the administration of intravenous magnesium sulfate, which peaks in 30 minutes, much sooner than 48 hours.

 CN: Physiological adaptation; CL: Create

17. 1,5,6. The use of magnesium sulfate as an anticonvulsant acts to depress the central nervous system by blocking peripheral neuromuscular transmissions and decreasing the amount of acetylcholine liberated. The primary goal of magnesium sulfate therapy is to prevent seizures. While being used, the temperature and pulse of the client should remain within normal limits. The respiratory rate needs to be >12 respirations per minute (rpm). Rates at 12 rpm or lower are associated with respiratory depression and are seen with magnesium toxicity. Renal compromise is identified with a urinary output of less than 30 mL/h. A fetal heart rate that is maintained within the 112 to 160 range is desired without later or variable decelerations. While extreme elevations of blood pressure must be treated, achieving a normal pressure carries the risk of decreasing perfusion to the fetus. Deep tendon reflexes should not be diminished or exaggerated. The therapeutic magnesium sulfate level of 5 to 8 mg/dL (2.5 to 4 mmol/L) is to be maintained.

 CN: Pharmacological and parenteral therapies; CL: Evaluate

18. 1. A respiratory rate of 12 breaths/min suggests potential respiratory depression, an adverse effect of magnesium sulfate therapy. The medication must be stopped, and the **HCP**  should be notified immediately. A patellar reflex of +2 is normal. Absence of a patellar reflex suggests magnesium toxicity. A blood pressure reading of 160/88 mm Hg would be a common finding in a client with severe preeclampsia. Urinary output exceeding intake is not likely in a client receiving intravenous magnesium sulfate. Oliguria is more common.

 CN: Pharmacological and parenteral therapies; CL: Synthesize

19. 3. Principles of emergency management begin with calling for assistance. If a client begins to have a seizure, the first action by the nurse is to remain with the client and call for immediate assistance. The nurse needs to have some assistance in managing this client. After the seizure, the client needs intensive monitoring. An airway can be inserted, if appropriate, after the seizure ends. Noting the time the seizure begins and ends and turning the client to her left side should be done after assistance is obtained.

 CN: Reduction of risk potential; CL: Synthesize

20. 1. One of the most common adverse effects of the drug hydralazine is tachycardia. Therefore, the nurse should assess the client's heart rate and pulse. Hydralazine acts to lower blood pressure by peripheral dilation without interfering with placental circulation. Bradypnea and polyuria are usually not associated with hydralazine use. Dysphagia is not a typical adverse effect of hydralazine.

 CN: Pharmacological and parenteral therapies; CL: Analyze

21. 4. These findings would be documented as 4+. 1+ indicates a diminished response; 2+ indicates a normal response; 3+ indicates a response that is brisker than average but not abnormal. Mild clonus is said to be present when there are two movements.

 CN: Physiological adaptation; CL: Apply

22. 3. Epigastric pain or acute right upper quadrant pain is associated with the development of eclampsia and an impending seizure; this is thought to be related to liver ischemia. Decreased contraction intensity is unrelated to the severity of the preeclampsia. Typically, the client's temperature increases because of increased cerebral pressure. A decrease in temperature is unrelated to an impending seizure. Hyporeflexia is not associated with an impending seizure. Typically, the client would exhibit hyperreflexia.

 CN: Physiological adaptation; CL: Analyze

23. 4. After an eclamptic seizure, the client commonly falls into a deep sleep or coma. The nurse must continually monitor the client for signs of impending labor because the client will not be able to verbalize that contractions are occurring. Oliguria is more common than polyuria after an eclamptic seizure. Facial flushing is not common unless it is caused by a reaction to a medication. Typically, the client remains hypertensive unless medications such as magnesium sulfate are administered.

 CN: Physiological adaptation; CL: Analyze

24. 1. After an eclamptic seizure, the client is at risk for abruptio placentae due to severe vasoconstriction resulting in hemorrhage into the decidua

basalis. Abruption placentae is manifested by a board-like abdomen and an abnormal fetal heart rate tracing. Transverse lie or shoulder presentation, placenta accreta, and uterine atony are not related to eclampsia. Causes of a transverse lie may include relaxation of the abdominal wall secondary to grand multiparity, preterm fetus, placenta previa, abnormal uterus, contracted pelvis, and excessive amniotic fluid. Placenta accreta, a rare phenomenon, refers to a condition in which the placenta abnormally adheres to the uterine lining. Uterine atony, or relaxed uterus, may occur after childbirth, leading to postpartum hemorrhage.

CN: Physiological adaptation; CL: Analyze

25. 2. The normal value of LDH in a nonpregnant person is 45 to 90 U/L (0.75 to 1.5 μ kat/L). LDH elevations indicate tissue destruction that can occur with HELLP syndrome. This platelet range is in the normal range and remains unchanged during pregnancy. Uric acid in a nonpregnant woman is 2 to 6.6 mg/dL (119 to 393 μ mol/L). AST normal range is 4 to 20 U/L (0.07 to 0.33 μ kat/L).

CN: Reduction of risk potential; CL: Synthesize

The Pregnant Client with a Chronic Hypertensive Disorder

26. 1. Pregnancy is not the time for clients to begin a diet. Clients with chronic hypertension need to consume adequate calories to support fetal growth and development. They also need an adequate protein intake. Meat and beans are good sources of protein. Most pregnant women report that eating more frequent, smaller meals decreases heartburn resulting from the reflux of acidic secretions into the lower esophagus. Pregnant women need adequate hydration (fluids) and fiber to prevent constipation.

CN: Basic care and comfort; CL: Evaluate

27. 2. Women with chronic hypertension during pregnancy are at risk for complications such as preeclampsia (about 25%), abruption placentae, and intrauterine growth retardation, resulting in a small-for-gestational-age infant. There is no association between chronic hypertension and hyperthyroidism. Pregnant women with chronic hypertension are not at an increased risk for hydramnios (polyhydramnios), an abnormally large amount of amniotic fluid.

Clients with diabetes and multiple gestations are at risk for this condition. Placenta accreta, a rare placental abnormality, refers to a condition in which the placenta abnormally adheres to the uterine lining. It is not associated with chronic hypertension.

CN: Reduction of risk potential; CL: Evaluate

28. 2,3,6. Vaginal bleeding with or without pain could signify placenta previa or abruptio placentae. Continuous or pounding headache could indicate an elevated blood pressure, and change in the strength or frequency of fetal movements could indicate that the fetus is in distress. Orthostatic hypotension can occur during pregnancy and can be alleviated by rising slowly. Leg veins may increase in size due to additional pressure from the increasing uterine size, while leg cramps may also occur and can commonly be decreased with calcium supplements.

CN: Reduction of risk potential; CL: Evaluate

The Pregnant Client with Third-Trimester Bleeding

29. 1. Bright red vaginal bleeding without contractions could indicate a placenta previa. A sterile vaginal exam should never be done on a woman with a known or suspected placenta previa. Applying the external fetal monitor will allow the nurse to assess fetal status. A complete physical assessment of the client is indicated. A fundal height is used to monitor fetal growth during pregnancy but does not provide information related to vaginal bleeding.

CN: Reduction of risk potential; CL: Analyze

30. 3. Urinary output of less than 30 mL/h indicates renal compromise and would be the most important assessment finding to report to the **HCP**. The APTT is within normal limits, and the hemoglobin is lower than values for an adult female but within normal limits for a pregnant female. Although the platelet level is slightly low and may impact blood clotting, when compared to renal failure, it is less important.

CN: Management of care; CL: Synthesize

31. 4. Although the exact cause of abruptio placentae is unknown, possible

contributing factors include excessive intrauterine pressure caused by hydramnios or multiple pregnancy, cocaine use, cigarette smoking, alcohol ingestion, trauma, increased maternal age and parity, and amniotomy. A history of hypertension is associated with an increased risk of abruptio placentae. A previous low transverse cesarean section and a history of one induced abortion are associated with increased risk of placenta previa, not abruptio placentae.

CN: Physiological adaptation; CL: Analyze

32. 2. Treatment of DIC includes treating the causative factor, replacing maternal coagulation factors, and supporting physiologic functions. Intravenous infusions of whole blood, fresh frozen plasma, or platelets are used to replace depleted maternal coagulation factors. Although Ringer's lactate solution and 5% dextrose solution may be used as intravenous fluid replacement, the client needs blood component therapy. Therefore, normal saline must be used. Intravenous heparin, not warfarin, may be administered to halt the clotting cascade.

CN: Physiological adaptation; CL: Analyze

33. 1. The most common assessment finding associated with placenta previa is painless vaginal bleeding. With placenta previa, the placenta is abnormally implanted, covering a portion or all of the cervical os. Uterine tetany, intermittent pain with spotting, and dull lower back pain are not associated with placenta previa. Uterine tetany is associated with oxytocin administration. Intermittent pain with spotting commonly is associated with a spontaneous abortion. Dull lower back pain is commonly associated with poor maternal posture or a urinary tract infection with renal involvement.

CN: Physiological adaptation; CL: Analyze

34. 1. When administering blood replacement therapy, extreme caution is needed. Before administering any blood product, the nurse should validate the client information and the blood product with another nurse to prevent administration of the wrong blood transfusion. Although baseline vital signs are necessary, she should initiate the infusion of blood slowly for the first 10 to 15 minutes. Then, if there is no evidence of a reaction, she should adjust the rate of infusion to ensure that the blood product is infused over 2 to 4

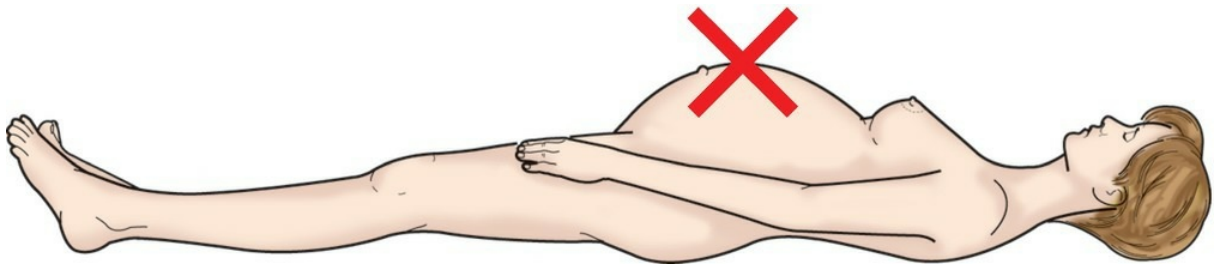

hours. The nurse can ask the client if she has ever had a reaction to a blood product, but a general question about allergies may not elicit the most complete response about any reactions to blood product administration. Blood transfusions are typically given with intravenous normal saline solution, not dextrose solutions.

 CN: Pharmacological and parenteral therapies; CL: Apply

35. 3. Feelings of loss, grief, and guilt are normal after a cesarean birth, particularly if it was not planned. The nurse should support the client, listen with empathy, and allow the client time to grieve. The likelihood of the client experiencing postpartum blues is not known, and no evidence is presented. Although maternal-infant bonding may be delayed owing to neonatal complications or maternal pain and subsequent medications, it should not be difficult. Although the nurse is aware that this type of birth was necessary to save the client's life, using this as the basis for the response does not acknowledge the mother's feelings.

 CN: Psychosocial integrity; CL: Apply

36. The level of anesthesia achieved via epidural anesthesia for a vaginal birth is T10 (approximately the level of the umbilicus). Epidural anesthesia for a cesarean birth would be at the level of T4 to T6, approximately the nipple line.

 CN: Pharmacological and parenteral therapies; CL: Apply

37. 3. Abruptio placentae is a medical emergency because the degree of hypovolemic shock may be out of proportion to visible blood loss. On admission, the nurse should plan to first insert a large-gauge intravenous catheter for fluid replacement and oxygen by mask to decrease fetal anoxia. Vaginal examination usually is not performed on pregnant clients who are experiencing third-trimester bleeding due to abruptio placentae because it can

result in damage to the placenta and further fetal anoxia. The client's history can be obtained once the client has been admitted and the intravenous line has been started. The goal is birth of the fetus, usually by emergency cesarean section. The nurse should also plan to monitor the client's vital signs and the fetal heart rate. Ultrasound is of limited use in the diagnosis of abruptio placentae.

CN: Reduction of risk potential; CL: Synthesize

The Pregnant Client with Preterm Labor

38. 3. The absence of fetal fibronectin in a vaginal swab between 22 and 37 weeks' gestation indicates there is less than 1% risk of developing preterm labor in the next week. Fetal fibronectin is an extra cellular protein normally found in fetal membranes and deciduas and has no correlation with preeclampsia, fetal lung maturation, or gestational diabetes.

CN: Reduction of risk potential; CL: Synthesize

39. 4. Smoking is a major risk factor for preterm labor and decreased fetal weight. Clients struggling to quit should know decreasing cigarette use will help improve outcomes even if they cannot totally quit. Dehydration is a risk factor for preterm labor as is prolonged standing and remaining in one position. Infection anywhere in the body can lead to preterm labor through the inflammation pathway. While taking trips, frequent emptying of the bladder prevents infection and ambulates the woman.

CN: Management of care; CL: Evaluate

40. 1. Indomethacin has been successfully used to halt preterm labor. However, if the client should give birth to a preterm infant, the nurse would notify the nursery personnel about the tocolytic therapy because this drug can lead to premature closure of the fetal ductus arteriosus, resulting in pulmonary hypertension. Prematurity is associated with RDS because of the immaturity of the fetal lungs. RDS is not a result of indomethacin. Hyperbilirubinemia is more common in preterm infants. Use of indomethacin to halt preterm labor is not associated with cardiomyopathy in the infant.

CN: Pharmacological and parenteral therapies; CL: Synthesize

41. 2. Corticosteroids given IM have been shown to increase fetal lung maturity by increasing surfactant and reduce the risk of respiratory distress syndrome in premature infants. It is not a guarantee that a premature newborn would not have problems at birth that would require time in the neonatal intensive care unit. The administration of the corticosteroids is normally completed within 24 to 48 hours.

CN: Pharmacological and parenteral therapies; CL: Evaluate

42. 3. As the uterus contracts, the abdominal wall rises and, when external monitoring is used, presses against the transducer. This movement is transmitted into an electrical current, which is then recorded. With the fetus in the LOA position, the cardiotransducer should be placed below the umbilicus on the side where the fetal back is located and uterine displacement during contractions is greatest. If the fetal back is near the symphysis pubis, the fetus is presenting as a transverse lie. If the fetus is in a breech position, the fetal back may be at or above the umbilicus.

CN: Reduction of risk potential; CL: Apply

43. 1. Betamethasone therapy is indicated when the fetal lungs are immature. The fetus must be between 28 and 34 weeks' gestation, and birth must be delayed for 24 to 48 hours for the drug to achieve a therapeutic effect. Antibiotics would be used to treat chorioamnionitis. Betamethasone is not an antagonist for tocolytic therapy. It increases, not decreases, the production of neonatal surfactant.

CN: Pharmacological and parenteral therapies; CL: Apply

44. 4. The shake test helps determine the maturity of the fetal pulmonary system. The test is based on the fact that surfactant foams when mixed with ethanol. The more stable the foam, the more mature the fetal pulmonary system. A lecithinsphingomyelin ratio is usually determined in conjunction with the shake test. Amniotic fluid volumes are used to evaluate the GI and urinary systems. Ultrasound to evaluate the cardiovascular system.

CN: Reduction of risk potential; CL: Apply

The Pregnant Client with Premature Rupture of the

Membranes

45. 3. Because an intrauterine infection may occur when membranes have ruptured, vaginal cultures for *N. gonorrhoeae*, group B streptococcus, and chlamydia are usually taken. Prophylactic antibiotics may be prescribed to reduce the risk of infection in the newborn. Frequent vaginal examinations should be avoided because they can further increase the client's risk for infection. Intravenous oxytocin to initiate labor may be used if an infection occurs. Bed rest can sometimes prolong the pregnancy and prevent a preterm birth. A sonogram may be used to validate rupture of the membranes with an amniotic fluid index. However, it is not needed if the **HCP** has confirmed the rupture.

CN: Reduction of risk potential; CL: Apply

46. 3. If the client's membranes have ruptured, the nitrazine paper will turn blue, an alkaline reaction. False positives may occur when the nitrazine paper is exposed to blood or semen. The definitive test for rupture of membranes is fern testing, where amniotic fluid is allowed to dry on a slide and then viewed under a microscope. Dried amniotic fluid will form a fern pattern. No other fluid forms this type of pattern.

CN: Reduction of risk potential; CL: Analyze

47. 4. Premature rupture of the membranes is commonly associated with chorioamnionitis, or an infection. A priority assessment for the nurse to make is to document the client's temperature every 2 to 4 hours. Temperature elevation may indicate an infection. Lethargy and an elevated white blood cell count also indicate an infection. The red blood cell count would provide information related to anemia, not infection. The client is not in labor. Therefore, assessing the degree of discomfort is not a priority at this time. Urinary output is not a reliable indicator of an infection such as chorioamnionitis.

CN: Reduction of risk potential; CL: Analyze

48. 1. Because group B streptococcus is a gram-positive bacterium, the **HCP** probably will prescribe intravenous penicillin to treat the mother's infection and prevent fetal infection. Gentamicin sulfate, which acts on gram-

negative bacteria, would be inappropriate. Administering a corticosteroid, such as betamethasone, is inappropriate because the premature rupture of the membranes enhances fetal lung maturity. The lack of amniotic fluid causes early maturation of lung tissue. Cefaclor, which is available only in the oral form, is used for upper and lower respiratory tract infections and urinary tract infections by gram-negative staphylococci.

CN: Pharmacological and parenteral therapies; CL: Analyze

49. 4. Because of the client's increased risk for infection, successful teaching is indicated when the client states that she will contact the primary care provider if her temperature is 100.4°F (38°C) or greater. The client should be instructed to monitor her temperature twice daily. The client should refrain from coitus, douching, and tub bathing, which can increase the potential for infection. Showering is permitted because water in the shower does not enter the vagina and increase the risk of infection. A fluid intake of at least 2 L daily is recommended to prevent potential urinary tract infection.

CN: Reduction of risk potential; CL: Evaluate

50. 1. The priority is to determine whether a prolapsed cord has occurred as a result of the spontaneous rupture of membranes. The nurse's first action should be to check the status of the fetal heart rate. Complications of premature rupture of the membranes include a prolapsed cord or increased pressure on the fetal umbilical cord inhibiting fetal nutrient supply. Variable decelerations or fetal bradycardia may be seen on the external fetal monitor. The cord also may be visible. Turning the client to her right side is not necessary. If the cord does prolapse, the client should be placed in a knee-to-chest or Trendelenburg position. Checking the fluid with nitrazine paper and vaginal examination are appropriate once the status of the fetus has been - evaluated.

CN: Reduction of risk potential; CL: Synthesize

The Pregnant Client with Diabetes Mellitus

51. 1,2,3,5. The gestational diabetic needs to maintain blood glucose levels as close to “normal” as the nondiabetic pregnant woman. Walking is an excellent form of exercise for anyone and works well for pregnant diabetics

as it burns calories, accelerates the heart rate, and as a result maintains the blood sugar at a lower level. During pregnancy, continuously high blood glucose levels measured by a hemoglobin A1C of >6 mg/dL (60 g/L) carry risks for the dyad. The suggested diet for a gestational diabetic is 1,800 to 2,400 cal/day to avoid the body breaking down maternal fat to maintain blood glucose levels. Continuing prenatal vitamins, iron, and folic acid (800 mcg/day) are general nutritional recommendations for pregnancy.

 CN: Reduction of risk; CL: Evaluate

52. 4. The nonstress test is considered reactive when two or more fetal heart rate accelerations of at least 15 bpm occur (from a baseline fetal heart rate of 120 to 160 bpm), along with fetal movement, during a 10- to 20-minute period. A reactive nonstress test indicates fetal heart rate accelerations and well-being. There is no indication for further evaluation (such as a contraction stress test). However, contraction stress tests are commonly scheduled for pregnant clients with insulin-dependent diabetes in the latter part of pregnancy and are repeated periodically until birth. Chorionic villus sampling is usually performed early in the pregnancy to detect fetal abnormalities.

 CN: Reduction of risk potential; CL: Synthesize

53. 3. A contraction stress test is used to evaluate fetal well-being during a simulated labor. A suspicious contraction stress test indicates inconsistent late deceleration patterns requiring further evaluation. A negative contraction stress test indicates no late decelerations and is the desired outcome. A positive contraction stress test indicates fetal compromise with frequent late decelerations. Fetal movements are one of the parameters of a biophysical profile and are detected with nonstress testing. Decreased or absent fetal movements may indicate central nervous system dysfunction or prematurity. Lack of fetal movement or decreased fetal movement is not associated with contraction stress testing.

 CN: Reduction of risk potential; CL: Analyze

54. 2. The fetal biophysical profile, a noninvasive test using real-time ultrasound, assesses five parameters: fetal heart rate reactivity, fetal breathing movements, gross fetal body movements, fetal tone, and amniotic fluid

volume. Fetal heart rate reactivity is determined by a nonstress test; the other four parameters are determined by ultrasound scanning. The results are available as soon as the test is completed and interpreted. The lecithin-sphingomyelin ratio is used to determine fetal lung maturity. Although the fetal biophysical profile is useful in predicting which fetuses may be at greater risk for compromise, there is no correlation with the newborn's Apgar score. The biophysical score is sometimes referred to as the fetal Apgar score. A score of 8 to 10 indicates fetal well-being. Use of an ultrasound requires the mother to have a full bladder.

CN: Pharmacological and parenteral therapies; CL: Apply

55. 2. During the first trimester, it is not unusual for insulin needs to decrease, commonly as a result of nausea and vomiting. Progressive insulin resistance is characteristic of pregnancy, particularly in the second half of pregnancy. It is not unusual for insulin needs to increase by as much as four times the nonpregnant dose after about the 24th week of gestation. This resistance is caused by the production of human placental lactogen, also called *human chorionic somatotropin*, by the placenta and by other hormones, such as estrogen and progesterone, which are insulin antagonists.

CN: Pharmacological and parenteral therapies; CL: Apply

56. 2. Clients who are pregnant and have diabetes are not at greater risk for multifetal pregnancy and subsequent twin-to-twin transfusion unless they have undergone fertility treatments. The pregnant diabetic client is at higher risk for complications such as infection, polyhydramnios, ketoacidosis, and preeclampsia, compared with the pregnant nondiabetic client.

CN: Reduction of risk potential; CL: Evaluate

57. 2. The goal is to maintain blood plasma glucose levels at 70 to 100 mg/dL (3.5 to 5.6 mmol/L) before meals and bedtime snacks. Below 60 mg/dL (5.6 mmol/L) indicates hypoglycemia. A range of 110 to 140 mg/dL (6.2 to 7.8 mmol/L) suggests hyperglycemia. The target range 1 hour after meals is 100 to 120 mg/dL (5.6 to 6.7 mmol/L).

CN: Pharmacological and parenteral therapies; CL: Synthesize

58. 3. Maternal infection is the most common cause of maternal

hyperglycemia and can lead to ketoacidosis, coma, and death. The client should notify the **healthcare provider (HCP)** immediately if she experiences symptoms of an infection. Fetal macrosomia results from maternal hyperglycemia, but does not cause it. Fetal insulin production increases as maternal glucose crosses the placenta. This helps control glucose in the fetus, but has no bearing on maternal glucose levels. Gestational hypertension does not cause maternal hyperglycemia during pregnancy.

 CN: Physiological adaptation; CL: Create

59. 1. Dehydration, polyuria, fatigue, flushed hot skin, dry mouth, and drowsiness are manifestations of hyperglycemia. Hyperglycemia is a medical emergency and requires immediate action to prevent maternal and fetal mortality. Pallor, sweating, and nervousness are early signs of hypoglycemia, not hyperglycemia.

 CN: Reduction of risk potential; CL: Evaluate

60. 4. Stillbirths caused by placental insufficiency occur with increased frequency in women with diabetes and severe preeclampsia. Clients with poorly controlled diabetes may experience unanticipated stillbirth as a result of premature aging of the placenta. Therefore, labor is commonly induced in these clients before term. If induction of labor fails, a cesarean section is necessary. Induction and cesarean section do not prevent neonatal hyperbilirubinemia, congenital anomalies, or perinatal asphyxia.

 CN: Reduction of risk potential; CL: Apply

61. 3. Maternal hyperglycemia and poor control of the mother's diabetes mellitus have been implicated in fetal macrosomia. When the mother is hyperglycemic, large amounts of amino acids, free fatty acids, and glucose are transferred to the fetus. Although maternal insulin does not cross the placenta, the fetal pancreas responds by hypertrophy of the islet cells of the pancreas. The islet cells produce large amounts of insulin, which acts as a growth hormone. A family history of large infants usually is not the reason for large-for-gestational-age fetuses in diabetic mothers. Maternal hypertension is associated with small-for-gestational-age fetuses because of vasoconstriction of the maternal and placental blood vessels.

 CN: Physiological adaptation; CL: Apply

62. 1. Insulin needs fall significantly for the first 24 hours postpartum because the client has usually been on nothing-by-mouth status for a period of time during labor and the labor process has used maternal glycogen stores. If the client breast-feeds, lower blood glucose levels decrease the insulin requirements. With insulin resistance gone, the client commonly needs little or no insulin during the immediate postpartum period. Although the need for insulin decreases during the intrapartum period, the insulin requirements fall further during the first 24 hours postpartum. After the first 24 hours postpartum, insulin requirements may fluctuate markedly, needing adjustment during the next few days as the mother's body returns to a nonpregnant state.

CN: Pharmacological and parenteral therapies; CL: Create

The Pregnant Client with Heart Disease

63. 3. The client needs a diet that is adequate in protein and calories to prevent anemia, which can place additional strain on the cardiac system, further compromising the client's cardiac status. The client should avoid contact with people who have infections because of the increased risk for developing endocarditis. The client may need antibiotics during the pregnancy to prevent endocarditis. Limiting sodium intake can help to prevent excessive expansion of blood volume and decrease cardiac workload.

CN: Reduction of risk potential; CL: Evaluate

64. 4. Clients with class II heart disease have dyspnea upon exertion but not at rest. Dyspnea at rest would indicate a change in condition that must be reported immediately because it may be indicative of increasing congestive heart failure. Mild ankle edema in the third trimester is a common finding. However, generalized or pitting edema, suggesting increasing congestive heart failure, must be reported immediately. Emotional stress on the job increases cardiac demand. However, it needs to be reported only if the client experiences symptoms, such as palpitations or irregular heart rate, indicating heart failure related to the increased stress. Weight gain of 1 lb (0.45 kg) per week is a normal finding during the third trimester.

CN: Reduction of risk potential; CL: Apply

65. 2. Unless the client has cardiac decompensation during the pregnancy, she will most likely be able to continue taking the same dose of medication. The client may be prescribed prophylactic antibiotics, particularly if she has had rheumatic fever. The medication would be switched only if digitalis toxicity occurs. A diuretic is added only if congestive heart failure is not controlled by sodium and activity restrictions.

 CN: Management of care; CL: Apply

66. 1. Although there is no completely safe anticoagulant therapy during pregnancy, heparin is typically the drug of choice. Warfarin, a pregnancy category D drug, can cause fetal malformations. Enoxaparin is sometimes used, but clients are typically switched to heparin near labor because enoxaparin used along with spinal or epidural anesthesia presents an increased risk of bleeding in the epidural or spinal space. Ardeparin also can cause fetal malformations.

 CN: Pharmacological and parenteral therapies; CL: Apply

67. 4. The client can continue a low-sodium diet but should increase the caloric intake to 2,200 calories daily to provide adequate nutrients to support fetal growth and development. Folic acid supplements, a standard component of care, are used to prevent folic acid deficiency, which is associated with megaloblastic anemia during pregnancy. Severe restriction of sodium intake is not recommended because sodium is necessary to maintain fluid volume. Iron supplements should be taken with acidic foods and fluids (e.g., citrus juices) for maximum absorption. Milk decreases the absorption of iron.

 CN: Reduction of risk potential; CL: Apply

The Client with an Ectopic Pregnancy

68. 1. The client's signs and symptoms indicate a probable ectopic pregnancy, which can be confirmed by ultrasound examination or by culdocentesis. The **HCP**  is notified immediately because hypovolemic shock may develop without external bleeding. Once the fallopian tube ruptures, blood will enter the pelvic cavity, resulting in shock. Abruptio placentae would be manifested by a board-like uterus in the third trimester. Gestational trophoblastic disease would be suspected if the client exhibited

no fetal heart rate and symptoms of pregnancy-induced hypertension before 20 weeks' gestation. A client with a complete abortion would exhibit a normal pulse and blood pressure with scant vaginal bleeding.

CN: Physiological adaptation; CL: Analyze

69. 1,2,3,5. The client may be experiencing an ectopic pregnancy. Contributing factors to an ectopic pregnancy include a prior history of sexually transmitted infection that can scar the fallopian tubes. Multiple sex partners increase the risk of sexually transmitted infections. Knowledge of the client's last menstrual period and contraceptive use may support or rule out the possibility of an ectopic pregnancy. The client's history of cesarean sections would not contribute information valuable to the client's current situation or potential diagnosis of ectopic pregnancy.

CN: Reduction of risk potential; CL: Analyze

70. 2. Diaphoresis, or profuse sweating, indicates shock, which occurs if the tube ruptures. Other common symptoms of tubal rupture include severe knife-like lower quadrant abdominal pain, referred shoulder pain, and falling blood pressure. The amount of vaginal bleeding that is evident is a poor estimate of actual blood loss. Slight vaginal bleeding, commonly described as *spotting*, is common. A rapid, thready pulse, a symptom of shock, is more common with tubal rupture than a slow, bounding pulse. Abdominal edema is a late sign of a tubal rupture in ectopic pregnancy.

CN: Reduction of risk potential; CL: Analyze

71. 4. Fallopian tube rupture is an emergency situation because of extensive bleeding into the peritoneal cavity. Shock soon develops if precautionary measures are not taken. The nurse readying a client for surgery should be especially careful to monitor blood pressure and pulse rate for signs of impending shock. The nurse should be prepared to administer fluids, blood, or plasma expanders as necessary through an intravenous line that should already be in place. Because the fertilized ovum has implanted outside the uterus, uterine cramping is unlikely. However, abdominal tenderness or knife-like pain may occur. Abdominal fullness may be present, but abdominal distention is rare unless peritonitis has developed. Although the hemoglobin and hematocrit may be checked routinely before surgery, the

laboratory results may not truly reflect the presence or degree of acute hemorrhage.

CN: Reduction of risk potential; CL: Analyze

72. 3. Anything that causes a narrowing or constriction in the fallopian tubes so that a fertilized ovum cannot be properly transported to the uterus for implantation predisposes an ectopic pregnancy. Pelvic inflammatory disease is the most common cause of constricted or narrow tubes. Developmental defects are other possible causes. Ectopic pregnancy is not related to urinary tract infections. Use of marijuana during pregnancy is not associated with ectopic pregnancy, but its use can result in cognitive reduction if the mother's use during pregnancy is extensive. Progestin-only contraceptives and intrauterine devices have been associated with ectopic pregnancy.

CN: Physiological adaptation; CL: Analyze

73. 3. Because the fallopian tube has not yet ruptured, methotrexate may be given, followed by leucovorin. This chemotherapeutic agent attacks the fast-growing zygote and trophoblast cells. RU-486 is also effective. A hysterosalpingogram is usually performed after chemotherapy to determine whether the tube is still patent. Progestin-only contraceptives and medroxyprogesterone are ineffective in clearing the fallopian tube. Dyphylline is a bronchodilator and is not used.

CN: Pharmacological and parenteral therapies; CL: Analyze

The Pregnant Client with Hyperemesis Gravidarum

74. 3. The client needs further instructions when she says she should eat two meals a day with frequent protein snacks to decrease nausea and vomiting. The client should eat more frequent, smaller meals, with frequent carbohydrate snacks to decrease nausea and vomiting. Eating dry crackers or toast before arising, consuming fluids separately from meals, and avoiding greasy or spicy foods may also help to decrease nausea and vomiting.

CN: Basic care and comfort; CL: Evaluate

75. 3. Gastrointestinal secretion losses from excessive vomiting, diarrhea, and excessive perspiration can result in hypokalemia, hyponatremia,

decreased chloride levels, metabolic alkalosis, and eventual acidosis if precautionary measures are not taken. Ketones may be present in the urine. Dehydration can lead to poor maternal and fetal outcomes. Persistent vomiting can lead to hypocalcemia, not hypercalcemia. Hyperbilirubinemia, not hypobilirubinemia, is typical in clients with hyperemesis. Persistent vomiting may affect liver function and subsequently the excretion of bilirubin from the body. Hypoglycemia, not hyperglycemia, may occur as a result of decreased intake of food and fluids, decreased metabolism of nutrients, and excessive vomiting.

CN: Reduction of risk potential; CL: Analyze

76. 2. Although the cause of hyperemesis is still unclear, it is thought to be related to high estrogen and human chorionic gonadotropin levels or to trophoblastic activity or gonadotropin production. Hyperemesis is also associated with infectious conditions, such as hepatitis or encephalitis, intestinal obstruction, peptic ulcer, and hydatidiform mole. Progesterone is a relaxant used during pregnancy and would not stimulate vomiting. Somatotropin is a growth hormone used in children. Aldosterone is a male hormone.

CN: Physiological adaptation; CL: Apply

77. 25 gtts/min

$$\frac{\text{gtts}}{\text{min}} = \frac{12 \text{ gtts}}{1 \text{ mL}} \times \frac{1,000 \text{ mL}}{8 \text{ h}} \times \frac{1 \text{ h}}{60 \text{ min}} = 25 \text{ gtts / min}$$

CN: Pharmacological and parenteral therapies; CL: Apply

78. 2. Clients with hyperemesis gravidarum can experience severe vomiting. Some clients will require hospital care to treat dehydration including intravenous fluids, antiemetics, and enteral nutrition. Sleep and dietary choices are important to care but not the priority intervention. Acetaminophen suppositories are not indicated for the care of hyperemesis gravidarum.

CN: Management of care; CL: Analyze

The Client with a Gestational Trophoblastic Disease

79. 4. The nurse should prepare the client for an ultrasound to determine the cause of the symptoms. Elevated blood pressure at this point in the pregnancy could indicate chronic hypertension as well as hydatidiform mole. The fundal height of 19 cm is higher than is typically found at 15 weeks' gestation and is indicative of a molar pregnancy (hydatidiform mole). The dark brown vaginal bleeding in isolation could indicate an abortion but when placed in context of the other symptoms is likely related to a hydatidiform mole. The continuous nausea and vomiting is abnormal at this point in the pregnancy and can be a result of the high levels of progesterone from a molar pregnancy. There is no fetus involved; the blood pressure elevation and the continuous nausea and vomiting will resolve with evacuation of the mole, negating the need for magnesium sulfate therapy and placing the client on NPO status. Transferring the client to the antenatal unit is premature before a diagnosis has been made.

CN: Reduction of risk potential; CL: Synthesize

80. 1. Hydatidiform mole is suspected when the following are present: gestational hypertension before the 24th week of gestation, brownish or prune-colored vaginal bleeding, anemia, absence of fetal heart tones, passage of hydropic vessels, uterine enlargement greater than expected for gestational age, and increased human chorionic gonadotropin levels. Gestational diabetes is related to an increased risk of preeclampsia and urinary tract infections, but it is not associated with hydatidiform mole. Hyperthyroidism, not hypothyroidism, occurs occasionally with hydatidiform mole. If it does occur, it can be a serious complication, possibly life threatening to the mother and fetus from cardiac problems. Polycythemia is not associated with hydatidiform mole. Rather, anemia from blood loss is associated with molar pregnancies.

CN: Reduction of risk potential; CL: Analyze

81. 2. After D&C to evacuate a molar pregnancy, the nurse should assess the client's vital signs and monitor for signs of hemorrhage, because the surgical procedure may have traumatized the uterine lining, leading to hemorrhage. Urinary tract infections, not common after evacuation of a molar

pregnancy, are most commonly related to urinary catheterization. Typically, urinary catheters are not used during evacuation of a molar pregnancy. The client should not experience abdominal distention because the contents of the uterus have been removed. Chorioamnionitis is an inflammation of the amniotic fluid membranes. With complete mole, no embryonic or fetal tissue or membranes are present.

CN: Reduction of risk potential; CL: Analyze

82. 2. A client who has had a hydatidiform mole removed should have regular checkups to rule out the presence of choriocarcinoma, which may complicate the client's clinical picture. The client's human chorionic gonadotropin (hCG) levels are monitored for 1 year. During this time, she should be advised not to become pregnant because this would be reflected in rising hCG levels. Ectopic or multifetal pregnancy is not associated with hydatidiform mole. Women who have molar pregnancies have fertility rates similar to the general population.

CN: Reduction of risk potential; CL: Synthesize

83. 2. A client who has experienced a molar pregnancy is at risk for development of choriocarcinoma and requires close monitoring of human chorionic gonadotropin (hCG) levels. Pregnancy would interfere with monitoring these levels. High hCG titers are common for up to 7 weeks after the evacuation of the mole, but then, these levels gradually begin to decline. Clients should have a pelvic examination and a blood test for hCG titers every month for 6 months and then every 2 months for 1 year. Gradually declining hCG levels suggest no complications. Increasing levels are indicative of a malignancy and should be treated with methotrexate. If after 1 year the hCG levels are negative, the client is theoretically free of the risk of a malignancy developing and could plan another pregnancy.

CN: Reduction of risk potential; CL: Apply

84. 2. Although the woman shows signs and symptoms typical of early pregnancy, in gestational trophoblastic disease, or molar pregnancy, gestational tissue exists but the pregnancy is not viable. The woman must have follow-up human chorionic gonadotropin (hCG) levels for the remaining 12 months to ensure remaining tissue does not turn malignant. Due

to the risks of developing malignancy, the woman must avoid pregnancy for at least 1 year following gestational trophoblastic disease. In a complete molar pregnancy, the villi swell and form cysts, and the woman is at risk for choriocarcinoma, which is a rapidly spreading malignancy.

CN: Health promotion and maintenance; CL: Evaluation

The Pregnant Client with Miscellaneous Complications

85. 4. Herpes simplex virus can be transmitted to the infant during a vaginal birth. The neonatal effects of herpes are severe enough that a cesarean birth is warranted if active lesions—primary or secondary—are present. A client with a primary infection during pregnancy sheds the virus for up to 3 months after the lesion has healed. The client carrying an infant weighing 8 lb (3,629 g) will be given a trial of labor before a cesarean. The client with a fetus in the right occiput posterior position will have a slow labor with increased back pain but can give birth vaginally. The fetus in a breech position still has many weeks to change positions before being at term. At 7 months' gestation, the breech position is not a concern.

CN: Physiological adaptation; CL: Evaluate

86. 3,2,5,1,4. The client's actions indicate distress, and the nurse should initiate emergency procedures. The nurse should first establish unresponsiveness and then ask staff to activate the emergency response system. Next, the nurse should follow CABs of CPR. The nurse should check the pulse and begin CPR. Then after 30 compressions, the nurse should assure the open airway and give two breaths.

CN: Management of care; CL: Synthesize

87. 4. Sickle cell disease is an autosomal recessive disorder requiring both parents to have a sickle cell trait to pass the disease to a child. Deoxygenated hemoglobin cells assume a sickle shape and obstruct tissues. Tissue obstruction causes hypoxia to the area (vasoocclusion) and results in pain, called *sickle cell crisis*. This type of anemia is an inherited disorder; it is not caused by lack of iron in the diet. Iron supplementation is needed only if there is laboratory evidence of iron deficiency anemia. Self-monitoring for any type of infections or sickle cell crisis and increased frequency of

antenatal care visits are part of the teaching plan of care.

CN: Physiological adaptation; CL: Evaluate

88. 1. The nurse should place a hand on the fetal head and provide gentle upward pressure to relieve the compression on the cord. Doing so allows oxygen to continue flowing to the fetus. The cord should never be placed back into the vagina because doing so may further compress it.

Administering oxygen is an appropriate measure but will not serve a useful purpose until the pressure is relieved on the cord, enabling perfusion to the infant. Turning the client to her left side facilitates better perfusion to the mother, but until the compression on the cord is relieved, the increased oxygen will not serve its purpose. Placing the client in a Trendelenburg or knee-chest position would be position changes to increase perfusion to the infant by relieving cord compression.

CN: Management of care; CL: Synthesize

89. 1,2,3,4. Having the fetus at a negative station places the client at risk for a cord prolapse. With a negative station, there is room between the fetal head and the maternal pelvis for the cord to slip through. A small infant is more mobile within the uterus, and the cord can rest between the fetus and the inside of the uterus or below the fetal head. With a large infant, the head is usually in a vertex presentation and occludes the lower portion of the uterus, preventing the cord from slipping by. When membranes rupture, the cord can be swept through with the amniotic fluid. In a breech presentation, the fetal head is in the fundus, and smaller portions of the fetus settle into the lower portion of the uterus, allowing the cord to lie beside the fetus. Prior abortion and a low-lying placenta have no correlation with cord prolapse.

CN: Physiological adaptation; CL: Analyze

90. 3. A postpartum client who saturates a pad in an hour or less at any time in the postpartum period is considered to be hemorrhaging. As the normal postpartum client heals, bleeding changes from red to pink to off-white. It also decreases in amount each day. Passing blood clots the size of a fist or larger is a reportable problem. Lochia varies in how long it lasts and is considered normal up to 6 weeks postpartum.

CN: Health promotion and maintenance; CL: Create

91. 2. RhoGAM is given to new mothers who are Rh negative and not previously sensitized and who have given birth to an Rh-positive infant. RhoGAM must be given within 72 hours of the birth of the infant because antibody formation begins at that time. The vaccine is used only when the mother has borne an Rh-positive infant—not an Rh-negative infant. RhoGAM is not given to a newborn and does not affect antigen formation.

CN: Pharmacological and parenteral therapies; CL: Evaluate

92. 2. The client is experiencing and verbalizing signs of postpartum depression, which usually appears at about 4 weeks postpartum but can occur at any time within the first year after birth. It is more severe and lasts longer than postpartum blues, also called “baby blues.” Baby blues are the mildest form of depression and are seen in the later part of the first week after birth. Symptoms usually disappear shortly. Depression may last several years and is disabling to the woman. Poor bonding may be seen at any time but commonly becomes evident as the mother begins interacting with the infant shortly after birth. Infant abuse may take the form of neglect or injuries to the infant. A depressed mother is at risk for injuring or abusing her infant.

CN: Reduction of risk potential; CL: Synthesize

93. 1,2,3. The **UAP** could assist the client with breathing and relaxation, and ambulate the postcesarean client to the bathroom. UAP can also remove Foley catheters in uncomplicated clients. Calculating the hourly IV totals for a preterm labor client would involve assessments that require nursing expertise. In-and-out catheterization, a sterile procedure, and calling reports to **HCPs**, which requires gathering and analysis of data, are responsibilities of the nurse.

CN: Management of care; CL: Evaluate

Managing Care, Quality, and Safety for Pregnant Clients

94. 3. A preeclamptic client with +3 proteinuria and epigastric pain is at risk for seizing, which would jeopardize the mother and the fetus. Thus, this client would be the highest priority. The client at 13 weeks’ gestation with nausea and vomiting is a concern because the presence of ketones indicates that her body does not have glucose to break down. However, this situation is

a lower priority than the preeclamptic client or the insulin-dependent diabetic. The insulin-dependent diabetic is a high priority; however, fetal movement indicates that the fetus is alive but may be ill. As few as four fetal movements in 12 hours can be considered normal. (The client may need additional testing to further evaluate fetal well-being.) The client who is at 17 weeks' gestation may be too early in her pregnancy to experience fetal movement and would be the last person to be seen.

 CN: Management of care; CL: Evaluate

95. 3. The nurse should refer the preeclamptic client with 3+ proteinuria to an **HCP**. The 3+ urine is significant, indicating there is much protein circulating. The woman who is 37 weeks' gestation with insulin-dependent diabetes who has experienced hypoglycemic episodes in the past week can be managed with food and glucose tablets until the client can obtain an appointment with the care provider. The client at 10 weeks' gestation with nausea and vomiting and +1 ketones should also be seen by an HCP, but at this point, although this client is uncomfortable, her life is not in danger. The 15-week client would not be expected to feel her baby move this soon in the pregnancy, and this would not be considered a problem that requires immediate referral to an HCP.

 CN: Management of care; CL: Evaluate

96. 3,2,1,4. The nurse should first change the IV magnesium sulfate and normal saline infusion rates and then assess the current status of the client. The nurse should then notify the **HCP** to explain the error and report the action taken. A medication error has occurred, and the nurse will need to initiate an incident report.

 CN: Management of care; CL: Synthesize

97. 1,2,4,3. If a client begins to have a seizure, the first action by the nurse is to remain with the client and call for immediate assistance. Next, the nurse should turn the client to her side and then maintain the airway by keeping the neck hyperextended. When the seizure is over, the nurse should assess the client for ruptured membranes and the fetal status.

 CN: Management of care; CL: Synthesize

98. 4. The first action taken should be to evaluate the placenta previa client who has pelvic pressure. The pelvic pressure may be caused by a fetal head creating pressure in the pelvis indicating a potential birth. This client should be evaluated without a pelvic exam and then consult with the **healthcare provider (HCP)** . A vaginal exam is contraindicated as it may stimulate bleeding of the placenta. The second action would be to complete an assessment on the client with preeclampsia and her fetus to evaluate for tolerance and effectiveness of the magnesium sulfate. The hyperemesis client needs to be evaluated for hydration status and for medication. The preterm labor client is stable on the oral medication and should be seen last.

CN: Management of care; CL: Apply

99. 2. A woman presenting at 30 weeks with nausea and vomiting and epigastric pain has signs and symptoms of preeclampsia and requires the nurse's attention first. Gravida 2, para 1 with spontaneous rupture of membranes, but no contractions, is not a priority. Gravida 5, para 1 at 37 weeks with pink discharge and abdominal cramping could be in early labor and is not a priority at this time. A gravida 1, para 0 at 39 weeks with bruises at various stages of healing could indicate she is in an abusive relationship, but this is not a priority at this time.

The Birth Experience

- The Primigravid Client in Labor
- The Multigravid Client in Labor
- The Labor Experience
- The Intrapartal Client with Risk Factors
- Managing Care, Quality, and Safety for Clients Giving Birth
- Answers, Rationales, and Test-Taking Strategies

The Primigravid Client in Labor

1. The nurse is managing care of a primigravida at full term who is in active labor. What should be included in developing the plan of care for this client?

- ☐ **1.** oxygen saturation monitoring every half hour
- ☐ **2.** supine positioning on back, if it is comfortable
- ☐ **3.** anesthesia/pain level assessment every 30 minutes
- ☐ **4.** vaginal bleeding, rupture of membrane assessment every shift

2. The healthcare provider (HCP) prescribes intermittent fetal heart rate monitoring for a 20-year-old obese primigravid client at 40 weeks' gestation in the first stage of labor. The nurse should monitor the client's fetal heart rate pattern at which interval?

- ☐ **1.** every 15 minutes during the latent phase
- ☐ **2.** every 30 minutes during the active phase
- ☐ **3.** every 60 minutes during the pushing phase
- ☐ **4.** every 2 hours during the transition phase

3. The primigravid client is at +1 station and 9 cm dilated. Based on these

data, the nurse should **first**:

- ☐ 1. ask the anesthesiologist to increase epidural infusion rate.
- ☐ 2. assist the client to push if she feels the need to do so.
- ☐ 3. encourage the client to breathe through the urge to push.
- ☐ 4. support family members in providing comfort measures.

4. Assessment of a primigravid client in active labor who has had no analgesia or anesthesia reveals complete cervical effacement, dilation of 8 cm, and the fetus at 0 station. The nurse should expect the client to exhibit which behavior during this phase of labor?

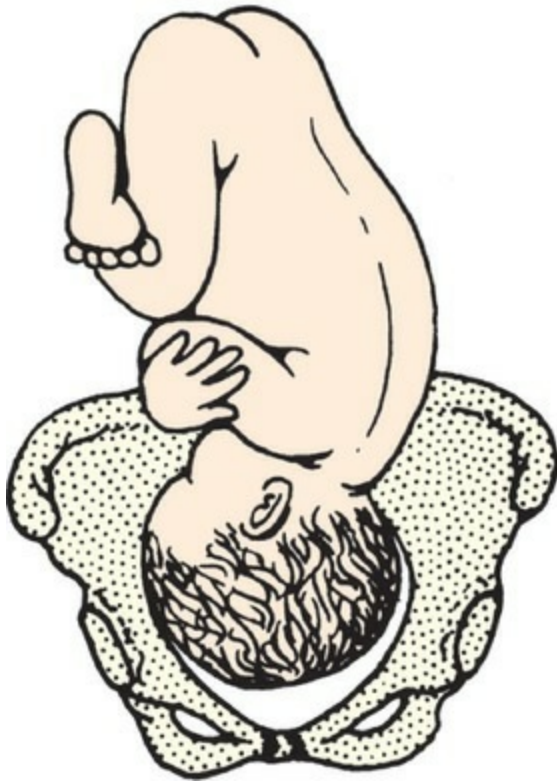

- ☐ 1. excitement
- ☐ 2. loss of control
- ☐ 3. numbness of the legs
- ☐ 4. feelings of relief

5. The nurse is explaining to a primigravida in labor that her baby is in a breech presentation, with the baby's presenting part in a left, sacrum, posterior (LSP) position. Which illustration should the nurse use to help the client understand how her baby is positioned?

- ☐ 1.

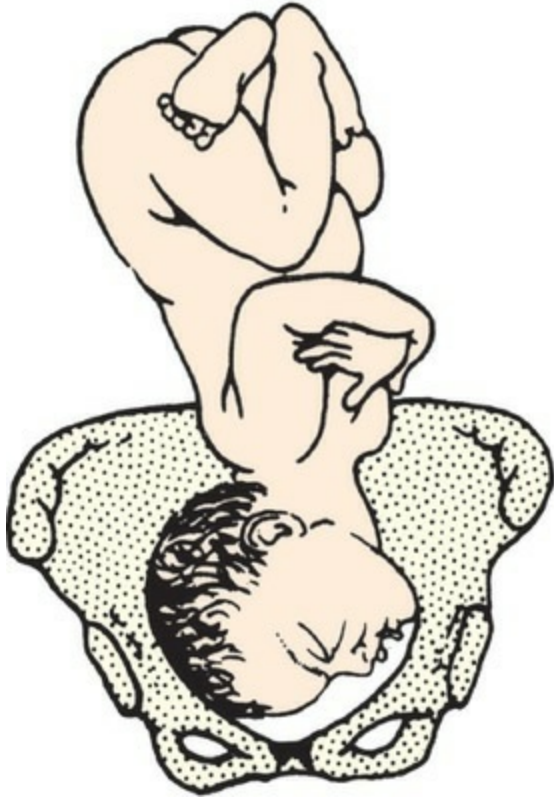

□ 2.

□ 3.

☐ 4.

6. The nurse is discussing pain relief methods for a pregnant first-time mother. The discussion should include which labor support methods? Select all that apply.

- ☐ 1. effleurage
- ☐ 2. positive reinforcement
- ☐ 3. guided imagery
- ☐ 4. pattern-paced breathing
- ☐ 5. self-containment theory
- ☐ 6. progressive relaxation

7. A primigravid client at 38 weeks' gestation comes to the labor room because "my water broke." The healthcare provider (HCP) asks the nurse to verify spontaneous rupture of membranes using nitrazine paper. The nurse observes that the nitrazine paper turns bright blue. The nurse's **next** action should be to:

- ☐ 1. notify the HCP that the membranes are ruptured.
- ☐ 2. perform a sterile vaginal examination to assess the cervix.

- ☐ 3. document the findings of the nitrazine test.
- ☐ 4. offer the client a sterile sanitary pad after performing perineal care.

8. The healthcare provider (HCP) has prescribed prostaglandin gel to be administered vaginally to a newly admitted primigravid client. Which finding indicates that the client has had a therapeutic response to the medication?

- ☐ 1. resting period of 2 minutes between contractions
- ☐ 2. normal patellar and elbow reflexes for the past 2 hours
- ☐ 3. softening of the cervix and beginning of effacement
- ☐ 4. leaking of clear amniotic fluid in small amounts

9. A primigravid client is admitted as an outpatient for an external cephalic version. Which factor would be a contraindication for the procedure?

- ☐ 1. multiple gestation
- ☐ 2. breech presentation
- ☐ 3. maternal Rh-negative blood type
- ☐ 4. history of gestational diabetes

10. A primigravida is admitted to the labor area with ruptured membranes and contractions occurring every 2 to 3 minutes, lasting 45 seconds. After 3 hours of labor, the client's contractions are now every 7 to 10 minutes, lasting 30 seconds. The nurse administers oxytocin as prescribed. The expected outcome of this drug is:

- ☐ 1. the cervix will begin to dilate 2 cm/h.
- ☐ 2. contractions will occur every 2 to 3 minutes, lasting 40 to 60 seconds, moderate intensity, resting tone between contractions.
- ☐ 3. the cervix will change from firm to soft, efface to 40% to 50%, and move from a posterior to anterior position.
- ☐ 4. contractions will be every 2 minutes, lasting 60 to 90 seconds, with intrauterine pressure of 70 mm Hg.

11. A primigravid client in the second stage of labor feels the urge to push. The client has had no analgesia or anesthesia. Anatomically, what would be the **best** position for the client to assume?

- ☐ 1. dorsal recumbent
- ☐ 2. lithotomy

- ☐ 3. hands and knees
- ☐ 4. squatting

12. A 21-year-old primigravid client at 40 weeks' gestation is admitted to the hospital in active labor. The client's cervix is 8 cm and completely effaced at 0 station. During the transition phase of labor, which is a **priority** nursing problem?

- ☐ 1. urinary retention
- ☐ 2. hyperventilation
- ☐ 3. ineffective coping
- ☐ 4. pain

13. A 24-year-old primigravid client who gives birth to a viable term neonate is prescribed to receive oxytocin intravenously after delivery of the placenta. Which sign would indicate to the nurse that the placenta is about to be delivered?

- ☐ 1. The cord lengthens outside the vagina.
- ☐ 2. There is decreased vaginal bleeding.
- ☐ 3. The uterus cannot be palpated.
- ☐ 4. The uterus changes to discoid shape.

14. A primiparous client, who has just given birth to a healthy term neonate after 12 hours of labor, holds and looks at her neonate and begins to cry. The nurse interprets this behavior as a sign of which response?

- ☐ 1. disappointment in the baby's gender
- ☐ 2. grief over the ending of the pregnancy
- ☐ 3. a normal response to the birth
- ☐ 4. indication of postpartum "blues"

15. The cervix of a 15-year-old primigravid client who has been admitted to the labor area is 2 cm dilated and 50% effaced. Her membranes are intact, and contractions are occurring every 5 to 6 minutes. Which intervention should the nurse recommend at this time?

- ☐ 1. resting in the right lateral recumbent position
- ☐ 2. lying in the left lateral recumbent position
- ☐ 3. walking around in the hallway

- ☐ 4. sitting in a comfortable chair for a period of time

16. Which technique to promote active relaxation would the nurse include in the teaching plan for a 16-year-old primigravid client in early labor?

- ☐ 1. relaxing uninvolved body muscles during uterine contractions
- ☐ 2. practicing being in a deep, meditative, sleep-like state
- ☐ 3. focusing on an object in the room during the contractions
- ☐ 4. breathing rapidly and deeply between contractions

17. The nurse is performing effleurage for a primigravid client in early labor. Which technique should the nurse use?

- ☐ 1. deep kneading of superficial muscles
- ☐ 2. secure grasping of muscular tissues
- ☐ 3. light stroking of the skin surface
- ☐ 4. prolonged pressure on specific sites

18. A 24-year-old primigravid client in active labor requests use of the jet hydrotherapy tub to aid in pain relief. Which condition would the nurse consider to be a contraindication for hydrotherapy?

- ☐ 1. ruptured membranes
- ☐ 2. multifetal gestation
- ☐ 3. diabetes mellitus
- ☐ 4. hypotonic labor patterns

19. The healthcare provider (HCP) prescribes an amniocentesis for a primigravid client at 37 weeks' gestation to determine fetal lung maturity. Which is an indicator of fetal lung maturity?

- ☐ 1. amount of bilirubin present
- ☐ 2. presence of red blood cells
- ☐ 3. Barr body determination
- ☐ 4. lecithin-sphingomyelin (L/S ratio)

20. A 19-year-old primigravid client at 38 weeks' gestation is 7 cm dilated, and the presenting part is at +1 station. The client tells the nurse, "I need to push!" What should the nurse do **next**?

- ☐ 1. Use the McDonald procedure to widen the pelvic opening.

- ☐ 2. Increase the rate of oxygen and intravenous fluids.
- ☐ 3. Instruct the client to use a pant-blow pattern of breathing.
- ☐ 4. Tell the client to push only when absolutely necessary.

21. What would be the **priority** when caring for a primigravid client whose cervix is dilated at 8 cm when the fetus is at 1+ station and the client has had no analgesia or anesthesia?

- ☐ 1. giving frequent sips of water
- ☐ 2. applying extra blankets for warmth
- ☐ 3. providing frequent perineal cleansing
- ☐ 4. offering encouragement and support

22. To determine whether a primigravid client in labor with a fetus in the left occipitoanterior (LOA) position is completely dilated, the nurse performs a vaginal examination. During the examination, the nurse should palpate which cranial sutures?

- ☐ 1. sagittal
- ☐ 2. lambdoidal
- ☐ 3. coronal
- ☐ 4. frontal

23. After a lengthy labor process, a primigravid client gives birth to a healthy newborn boy with a moderate amount of skull molding. What information would the nurse include when explaining to the parents about this condition?

- ☐ 1. It is typically seen with breech births.
- ☐ 2. It usually lasts a day or two before resolving.
- ☐ 3. It is typical when the brow is the presenting part.
- ☐ 4. Surgical intervention may be necessary to alleviate pressure.

24. The healthcare provider (HCP) has informed the labor nurse that he believes the uterus has inverted in a primiparous client who has just given birth. Which findings would help to confirm this diagnosis? Select all that apply.

- ☐ 1. hypotension
- ☐ 2. gush of blood from the vagina

- ☐ 3. intense, severe, tearing type of abdominal pain
- ☐ 4. uterus is hard and in a constant state of contraction
- ☐ 5. inability to palpate the uterus
- ☐ 6. diaphoresis

25. After the birth of a viable neonate, a 20-year-old primiparous client comments to her mother and the nurse about the baby. Which comment would the nurse interpret as a possible sign of potential maternal-infant bonding problems?

- ☐ 1. “He has got my funny-looking ears!”
- ☐ 2. “I think my mother should give him the first feeding.”
- ☐ 3. “He is a lot bigger than I expected him to be.”
- ☐ 4. “I want to buy him a blue outfit to wear when we get home.”

26. The nurse explains to a newly admitted primigravid client in active labor that, according to the gate-control theory of pain, a closed gate means that the client should experience what type of pain?

- ☐ 1. no pain
- ☐ 2. sharp pain
- ☐ 3. light pain
- ☐ 4. moderate pain

27. The cervix of a primigravid client in active labor who received epidural anesthesia 4 hours ago is now completely dilated, and the client is ready to begin pushing. Before the client begins to push, the nurse should assess:

- ☐ 1. fetal heart rate variability
- ☐ 2. cervical dilation again
- ☐ 3. status of membranes
- ☐ 4. bladder status

28. For the past 8 hours, a 20-year-old primigravid client in active labor with intact membranes has been experiencing regular contractions. The fetal heart rate is 136 bpm with good variability. After determining that the client is still in the latent phase of labor, the nurse should observe the client for:

- ☐ 1. exhaustion

- ☐ 2. chills and fever
- ☐ 3. fluid overload
- ☐ 4. meconium-stained fluid

29. A primigravid client whose cervix is 7 cm dilated with the fetus at 0 station and in a left occipitoposterior (LOP) position has severe back pain. What intervention is **most** indicated?

- ☐ 1. Provide firm pressure to the client's sacral area.
- ☐ 2. Prepare the client for a cesarean birth.
- ☐ 3. Prepare the client for a precipitate birth.
- ☐ 4. Maintain the client in a left side-lying position.

30. A primigravid client in active labor has had no anesthesia. The client's cervix is 7 cm dilated, and she is starting to feel considerable discomfort during contractions. The nurse should instruct the client to change from slow chest breathing to which breathing technique?

- ☐ 1. rapid, shallow chest breathing
- ☐ 2. deep chest breathing
- ☐ 3. rapid pant-blow breathing
- ☐ 4. slow abdominal breathing

31. The healthcare provider (HCP) prescribes scalp stimulation of the fetal head for a primigravid client in active labor. When explaining to the client about this procedure, what would the nurse include as the purpose?

- ☐ 1. assessment of the fetal hematocrit level
- ☐ 2. increase in the strength of the contractions
- ☐ 3. increase in the fetal heart rate and variability
- ☐ 4. assessment of fetal position

32. Assessment of a primigravid client reveals cervical dilation at 8 cm and complete effacement. The client has severe back pain during this phase of labor. The nurse explains that the client's severe back pain is **most** likely caused by the fetal occiput being in which position?

- ☐ 1. breech
- ☐ 2. transverse
- ☐ 3. posterior

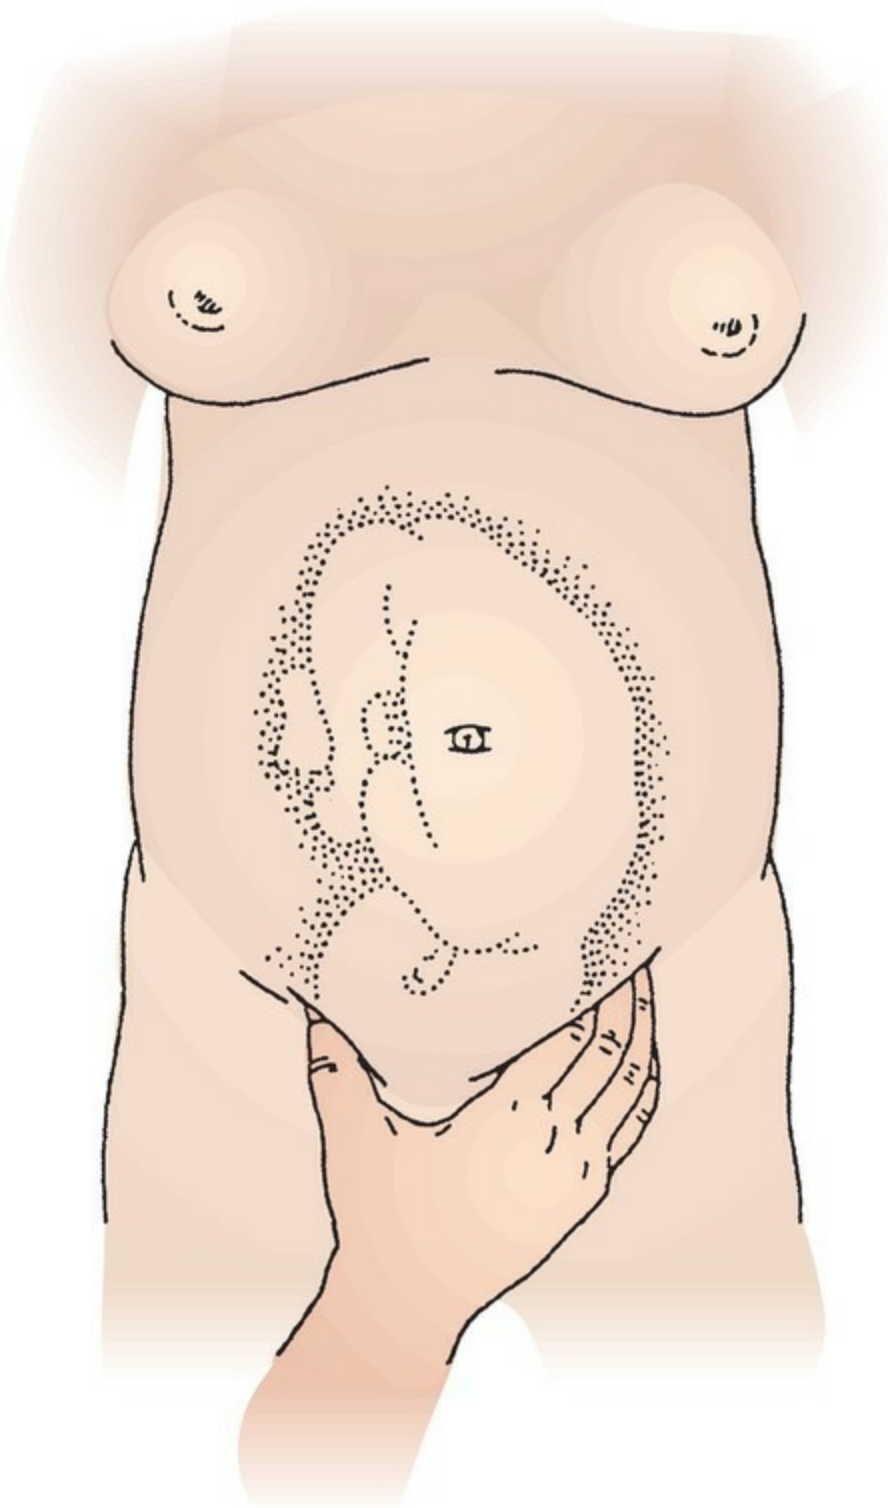

- ☐ 4. anterior

33. The nurse assesses a primiparous client with ruptured membranes in labor for 20 hours. The nurse identifies late decelerations on the monitor and initiates standard procedures for the labor client with this wave pattern.

Which interventions should the nurse perform? Select all that apply.

- ☐ 1. administering oxygen via mask to the client
- ☐ 2. questioning the client about the effectiveness of pain relief
- ☐ 3. placing the client on her side
- ☐ 4. readjusting the monitor to a more comfortable position
- ☐ 5. applying an internal fetal monitor

34. When performing Leopold's maneuvers on a primigravid client, the nurse is palpating the uterus as shown below. Which maneuver is the nurse performing?

- ☐ 1. first maneuver
- ☐ 2. second maneuver

- ☐ 3. third maneuver
- ☐ 4. fourth maneuver

35. Before placing the fetal monitoring device on a primigravid client's fundus, the nurse performs Leopold's maneuvers. The nurse explains that third maneuver is done for which reason?

- ☐ 1. to determine whether the fetal presenting part is engaged
- ☐ 2. to locate the fetal cephalic prominence
- ☐ 3. to distinguish between a breech and a cephalic presentation
- ☐ 4. to locate the position of the fetal arms and legs

The Multigravid Client in Labor

36. The nurse is caring for a G2, T1, P0, A0, L1 client at term. The client is completely effaced, dilated to 2 cm, with contractions every 3 minutes lasting 45 seconds. The client is asking for an epidural to make her more comfortable. Indicate the appropriate response by the nurse.

- ☐ 1. "We cannot give epidurals until you are 5 to 6 cm dilated. There is IV medication available if you would like it now."
- ☐ 2. "You cannot have an epidural until your membranes have ruptured."
- ☐ 3. "Your contraction pattern is slow at this point and will need to accelerate before you can have your epidural."
- ☐ 4. "It is too early in labor for the epidural, but you can have IV medication to keep you comfortable until you have dilated 1 to 2 cm more."

37. The nurse has just received report on a labor client: a G3, T1, P0, Ab1, L1 who is 80% effaced, 3 cm dilated, 0 station. The nurse anticipates the plan of care for the shift will address what factors? Select all that apply.

- ☐ 1. This client will give birth before the change of shift in 12 hours.
- ☐ 2. Pushing the baby out should take 30 minutes or less.
- ☐ 3. Contractions will remain irregular until transition.
- ☐ 4. Transition will be shorter for this multiparous client.
- ☐ 5. This client will withdraw into herself during transition.

38. A multigravida in active labor is 7 cm dilated. The fetal heart rate baseline is 130 bpm with moderate variability. The client begins to have

variable decelerations to 100 to 110 bpm. What should the nurse do **next**?

- ☐ 1. Perform a vaginal examination.
- ☐ 2. Notify the healthcare provider (HCP) of the decelerations.
- ☐ 3. Reposition the client, and continue to evaluate fetal heart rate.
- ☐ 4. Administer oxygen via mask at 2 L/min.

39. A nurse is preparing a change-of-shift report and has been caring for a multigravid client with a normally progressing labor. Which information should be part of this report? Select all that apply.

- ☐ 1. interpretation of the fetal monitor strip
- ☐ 2. analgesia or anesthesia being used
- ☐ 3. previous methods of birth control
- ☐ 4. support persons with the client
- ☐ 5. prior birth history

40. A multigravid client is admitted at 4-cm dilation and is requesting pain medication. The nurse gives the client nalbuphine 15 mg. Within 5 minutes, the client tells the nurse she feels like she needs to have a bowel movement. The nurse should **first**:

- ☐ 1. have naloxone available in the birthing room.
- ☐ 2. complete a vaginal examination to determine dilation, effacement, and station.
- ☐ 3. prepare for birth.
- ☐ 4. document the client's relief due to pain medication.

41. A multigravid laboring client has an extensive documented history of drug addiction. Her last reported usage was 5 hours ago. She is 2 cm dilated with contractions every 3 minutes of moderate intensity. The healthcare provider (HCP) prescribes nalbuphine 15 mg slow IV push for pain relief followed by an epidural when the client is 4 cm dilated. Within 10 minutes of receiving the nalbuphine, the client states she thinks she is going to have her baby now. Of the drugs available at the time of the birth, which should the nurse avoid using with this client in this situation?

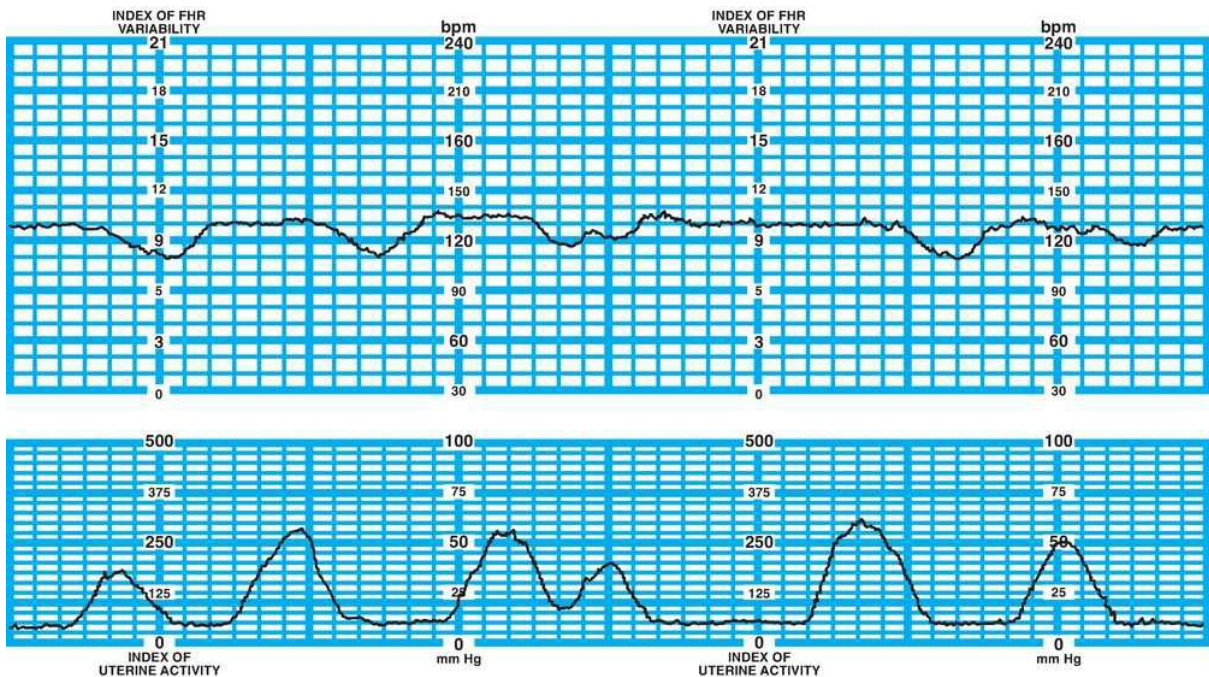

- ☐ 1. lidocaine 1%
- ☐ 2. naloxone

- ☐ 3. local anesthetic
- ☐ 4. pudendal block

42. A 31-year-old multigravid client at 39 weeks' gestation admitted to the hospital in active labor is receiving intravenous lactated Ringer's solution and a continuous epidural anesthetic. During the first hour after administration of the anesthetic, the nurse should monitor the client for:

- ☐ 1. hypotension.
- ☐ 2. diaphoresis.
- ☐ 3. headache.
- ☐ 4. tremors.

43. A 30-year-old G3, T2, P0, A0, L2 is being monitored internally. She is being induced with IV oxytocin because she is postterm. The nurse notes the pattern below. The client is wedged to her side while lying in bed and is approximately 6 cm dilated and 100% effaced. The nurse should **first**:

- ☐ 1. continue to observe the fetal monitor.
- ☐ 2. anticipate rupture of the membranes.
- ☐ 3. prepare for fetal oximetry.
- ☐ 4. discontinue the oxytocin infusion.

44. The nurse, while shopping in a local department store, hears a

multiparous woman say loudly, “I think the baby is coming.” After asking someone to call 911, the nurse assists the client to give birth to a term neonate. While waiting for the ambulance, the nurse suggests that the mother initiate breast-feeding, primarily for what reason?

- ☐ 1. to begin the parental-infant bonding process
- ☐ 2. to prevent neonatal hypothermia
- ☐ 3. to provide glucose to the neonate
- ☐ 4. to contract the mother’s uterus

45. Approximately 15 minutes after birth of a viable term neonate, a multiparous client has chills. What should the nurse do **next**?

- ☐ 1. Assess the client’s pulse rate.
- ☐ 2. Decrease the rate of intravenous fluids.
- ☐ 3. Provide the client with a warm blanket.
- ☐ 4. Assess the amount of blood loss.

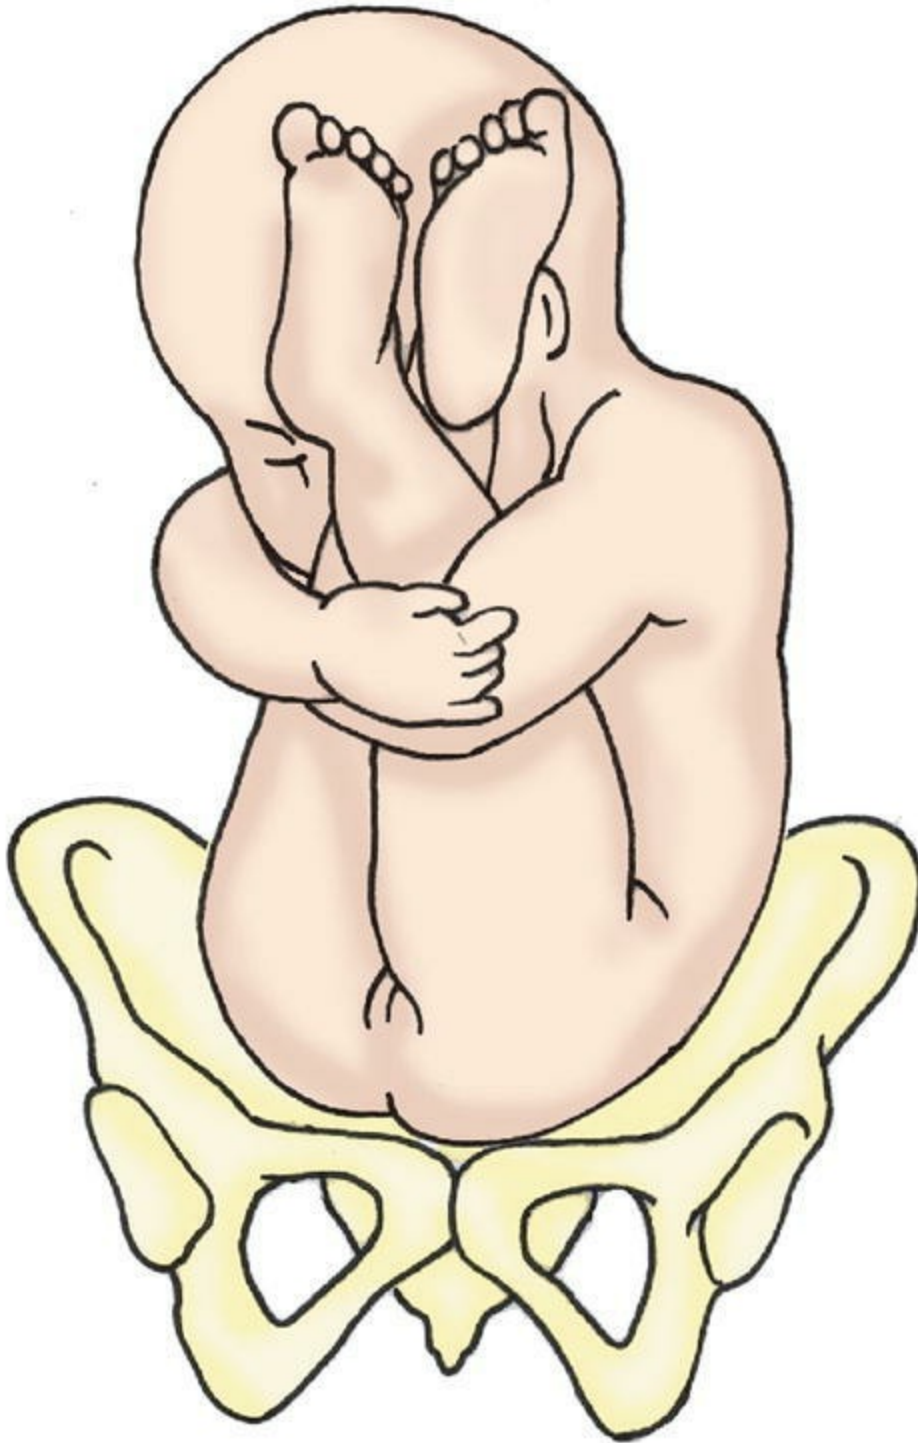

46. The healthcare provider (HCP) plans to perform an amniotomy on a multiparous client admitted to the labor area at 41 weeks’ gestation for labor induction. After the amniotomy, the nurse should **first**:

- ☐ 1. monitor the client’s contraction pattern.
- ☐ 2. assess the fetal heart rate (FHR) for 1 full minute.
- ☐ 3. assess the client’s temperature and pulse.
- ☐ 4. document the color of the amniotic fluid.

47. A multigravid client who is 10 cm dilated is admitted to the labor and birth unit. In addition to supporting the client, **priority** nursing care includes:

- ☐ 1. turning on the infant warmer.
- ☐ 2. increasing IV fluids.
- ☐ 3. determining the client’s preferences for pain control.
- ☐ 4. providing client education regarding care of the newborn.

48. The nurse is assessing fetal presentation in a multiparous client. The illustration below indicates which type of presentation?

- ☐ 1. frank breech
- ☐ 2. complete breech
- ☐ 3. footling breech
- ☐ 4. vertex

49. Two hours ago, a multigravid client was admitted in active labor with her cervix dilated at 5 cm and completely effaced and the fetus at 0 station. Currently, the client is experiencing nausea and vomiting, a slight chill with perspiration beads on her lip, and extreme irritability. The nurse should **first**:

- ☐ 1. warm the temperature of the room by a few degrees.
- ☐ 2. increase the rate of intravenous fluid administration.
- ☐ 3. obtain a prescription for an intramuscular antiemetic medication.
- ☐ 4. assess the client's cervical dilation and station.

50. What interval should the nurse use when assessing the frequency of contractions of a multiparous client in active labor admitted to the birthing area?

- ☐ 1. acme of one contraction to the beginning of the next contraction
- ☐ 2. beginning of one contraction to the end of the next contraction
- ☐ 3. end of one contraction to the end of the next contraction
- ☐ 4. beginning of one contraction to the beginning of the next contraction

51. While a client is being admitted to the birthing unit she states, "My water broke last night, but my labor started 2 hours ago." Which findings are a concern? Select all that apply.

- ☐ 1. maternal vital signs: T 99.5°F (37.5°C), HR 80, R 24, BP 130/80 mm Hg
- ☐ 2. blood and mucus on perineal pad
- ☐ 3. baseline fetal heart rate of 140 bpm with a range between 110 and 160 with contractions
- ☐ 4. peripad stained with green fluid
- ☐ 5. client stating, "This baby wants out—he keeps kicking me"

52. While the nurse is caring for a multiparous client in active labor at 36 weeks' gestation, the client tells the nurse, "I think my water just broke." What should the nurse do **first**?

- ☐ 1. Turn the client to the right side.
- ☐ 2. Assess the color, amount, and odor of the fluid.
- ☐ 3. Assess the fetal heart rate pattern.
- ☐ 4. Check the client's cervical dilation.

53. The nurse has obtained a urine specimen from a multiparous client admitted to the labor unit. The woman asks to go to the bathroom and reports that she feels she has to move her bowels. Which actions would be appropriate? Select all that apply.

- ☐ 1. assisting her to the bathroom
- ☐ 2. applying an external fetal monitor to obtain fetal heart rate
- ☐ 3. assessing her stage of labor
- ☐ 4. asking if she had back labor pains like this with any of her other birth experiences
- ☐ 5. allowing her support person to take her to the bathroom to maintain privacy
- ☐ 6. checking the degree of fetal descent

54. A multigravid client admitted to the labor area is scheduled for a cesarean birth under spinal anesthesia. Which client statement indicates teaching about spinal anesthesia has been understood?

- ☐ 1. "The medication will be administered while I am in prone position."
- ☐ 2. "The anesthetic may cause a severe headache, which is treatable."
- ☐ 3. "My blood pressure may increase if I lie down too soon after the injection."
- ☐ 4. "I can expect immediate anesthesia that can be reversed very easily."

55. The healthcare provider (HCP) determines that the fetus of a multiparous client in active labor is in distress, necessitating a cesarean birth with general anesthesia. Before the cesarean birth, the anesthesiologist prescribes cimetidine 300 mg PO. The nurse explains that the purpose of giving cimetidine is to:

- ☐ 1. incidence of bronchospasm
- ☐ 2. oral and respiratory secretions
- ☐ 3. acid level of the stomach contents
- ☐ 4. incidence of postoperative gastric ulcer

The Labor Experience

56. The nurse is performing a vaginal examination on a client in labor. The

nurse finds the fetal presenting part 1 cm above the ischial spines. The nurse should chart the station as:

- ☐ 1. -1 station.
- ☐ 2. +1 station.
- ☐ 3. engaged.
- ☐ 4. floating.

57. The nurse is managing a pregnant client's second stage of labor. The nurse should intervene when observing which action?

- ☐ 1. closed glottis pushing
- ☐ 2. open glottis pushing
- ☐ 3. "rest and descent"
- ☐ 4. squatting while pushing

58. A client in the second stage of labor who planned an unmedicated birth is in severe pain because the fetus is in the ROP position. The nurse should place the client in which position for pain relief?

- ☐ 1. lithotomy
- ☐ 2. right lateral position
- ☐ 3. hands and knees
- ☐ 4. tailor sitting

59. A woman who delivered her last infant by caesarean section is admitted to the hospital at term with contractions every 5 minutes. The healthcare provider (HCP) intends to have her undergo "a trial labor." The nurse explains to the client that:

- ☐ 1. labor will be stimulated with exogenous oxytocin until birth.
- ☐ 2. the HCP needs more information to determine the presence of true labor.
- ☐ 3. labor progress will be evaluated continually to determine appropriate progress for a vaginal birth.
- ☐ 4. labor will be arrested with tocolytic agents after a 2-hour period even if no fetal distress is noted.

60. The nurse prepares a client for lumbar epidural anesthesia. Before anesthesia administration, the nurse instructs the client to assume which

position?

- ☐ 1. lithotomy
- ☐ 2. side-lying
- ☐ 3. hands and knees
- ☐ 4. prone

61. A client in labor received an epidural for pain management. Before receiving the epidural, the client's blood pressure was 124/76 mm Hg. Ten minutes after receiving the epidural, the client's blood pressure is 98/56 mm Hg, and the mother is vomiting. Before calling the healthcare provider (HCP), the nurse should:

- ☐ 1. decrease the IV fluid rate.
- ☐ 2. turn the client to her side.
- ☐ 3. catheterize the client.
- ☐ 4. perform a vaginal examination.

62. A nurse is caring for a woman G1 P0 at 40 weeks' gestation in active labor. Assessments include cervix 5 cm dilated; 90% effaced; station 0; cephalic presentation; FHR baseline is 135 bpm and decreases to 125 bpm shortly after onset of five uterine contractions and returns to baseline before the uterine contraction ends.

Based on this assessment, what action should the nurse take **first**?

- ☐ 1. Position the client on her left side, and administer O₂ via face mask.
- ☐ 2. Document findings on the client's chart, and continue to monitor labor progress.
- ☐ 3. Perform vaginal exam to rule out umbilical cord prolapse.
- ☐ 4. Notify the healthcare provider (HCP) immediately, and prepare for emergency caesarean section.

63. The nurse is caring for a full-term, nonmedicated, primiparous client who is in the transition stage of labor. The client is writhing in pain and saying, "Help me, help me!" Her last vaginal exam 1 hour ago showed that she was 8 cm dilated, +1 station, and in what appeared to be a comfortable position. What does the nurse anticipate as the highest **priority** intervention in caring for this client?

- ☐ 1. Help the client through contractions until a narcotic can be given.
- ☐ 2. Palpate the bladder to see if it has become distended.
- ☐ 3. Ask the client for suggestions to make her more comfortable.
- ☐ 4. Perform a vaginal exam to determine if the client is fully dilated.

64. A client is admitted at 30 weeks' gestation with contractions every 3 minutes. Her cervix is 1 to 2 cm dilated and 75% effaced. Following a 4-g bolus dose, IV magnesium sulfate is infusing at 2 g/h. How will the nurse know the medication is having the intended effect?

- ☐ 1. Contractions will increase in frequency, leading to birth.
- ☐ 2. The client will maintain a respiratory rate > 12 breaths/min.
- ☐ 3. Contractions will decrease in frequency, intensity, and duration.
- ☐ 4. The client will maintain blood pressure readings of 120/80 mm Hg.

65. A client at 33 weeks' gestation is admitted in preterm labor. She is given betamethasone 12 mg IM every 24 hours $\times 2$. What is the expected outcome of this drug therapy?

- ☐ 1. The contractions will end within 24 hours.
- ☐ 2. The client will give birth to a neonate without infection.
- ☐ 3. The client will give birth to a full-term neonate.
- ☐ 4. The neonate will be born with mature lungs.

66. A full-term client is admitted for an induction of labor. The healthcare provider (HCP) has assigned a Bishop score of 10. Which drug would the nurse anticipate administering to this client?

- ☐ 1. oxytocin 30 units in 500 mL D₅W
- ☐ 2. prostaglandin gel 0.5 mg
- ☐ 3. misoprostol 50 mcg
- ☐ 4. dinoprostone 10 mg

67. A full-term client is admitted for induction of labor. When admitted, her cervix is effaced 25% but has not dilated. The initial goal is cervical ripening prior to labor induction. Which drug will prepare her cervix for induction?

- ☐ 1. nalbuphine

- ☐ 2. oxytocin
- ☐ 3. dinoprostone
- ☐ 4. betamethasone

68. The nurse is explaining the medication options available for pain relief during labor. The nurse realizes the client needs further teaching when the client makes which statement?

- ☐ 1. "Nalbuphine and promethazine will give relief from pain and nausea during early labor."
- ☐ 2. "I can have an epidural as soon as I start contracting."
- ☐ 3. "If I have a cesarean, I can have an epidural."
- ☐ 4. "If I have an emergency cesarean, I may be put to sleep for the birth."

69. The healthcare provider (HCP) has performed an amniotomy on a laboring client. Which details must be included in the documentation of this procedure? Select all that apply.

- ☐ 1. time of rupture
- ☐ 2. color and clarity of fluid
- ☐ 3. fetal heart rate (FHR) and pattern before and after the procedure
- ☐ 4. size of amnio hook used during the procedure
- ☐ 5. odor and amount of fluid

70. Following an epidural and placement of internal monitors, a client's labor is augmented. Contractions are lasting greater than 90 seconds and occurring every 1½ minutes. The uterine resting tone is >20 mm Hg with an abnormal fetal heart rate and pattern. Which action should the nurse take **first**?

- ☐ 1. Notify the healthcare provider (HCP).
- ☐ 2. Turn off the oxytocin infusion.
- ☐ 3. Turn the client to her left side.
- ☐ 4. Increase the maintenance IV fluids.

71. A nurse notices repetitive late decelerations on the fetal heart monitor. The **best** initial actions by the nurse include:

- ☐ 1. prepare for birth, reposition the client, and begin pushing.
- ☐ 2. perform sterile vaginal exam, increase IV fluids, and apply oxygen.

- ☐ 3. notify the provider, explain findings to the client, and begin pushing.
- ☐ 4. reposition the client, apply oxygen, and increase IV fluids.

72. A client is induced with oxytocin. The fetal heart rate is showing accelerations lasting 15 seconds and exceeding the baseline with fetal movement. What action associated with this finding should the nurse take?

- ☐ 1. Turn the client to her left side.
- ☐ 2. Administer oxygen via face mask at 10 to 12 L/min.
- ☐ 3. Notify the healthcare provider (HCP) of the situation.
- ☐ 4. Document fetal well-being.

73. As a nurse begins her shift on the obstetrical unit, there are several new admissions. The client with which condition would be a candidate for induction?

- ☐ 1. preeclampsia
- ☐ 2. active herpes
- ☐ 3. face presentation
- ☐ 4. fetus with late decelerations

74. A nurse and an unlicensed assistive personnel (UAP) are caring for clients in a labor and birth unit. Which task should the registered nurse (RN) assign to the UAP?

- ☐ 1. Perform a fundal check on a 2-day postpartum client.
- ☐ 2. Remove a fetal monitor, and assist a client to the bathroom.
- ☐ 3. Give ibuprofen 800 mg by mouth to a newly postpartum client.
- ☐ 4. Teach a new mother how to bottle-feed her infant.

75. A laboring client smiles pleasantly at the nurse when asked simple questions. The client speaks only Mandarin, and the interpreter is busy with an emergency situation. At her last vaginal examination, the client was 5 cm dilated, 100% effaced, and at 0 station. While working with this client, which response indicates that the client may be approaching birth?

- ☐ 1. The fetal monitor strip shows late decelerations.
- ☐ 2. The client begins to speak to her family in her native language.
- ☐ 3. The fetal monitor strip shows early decelerations.
- ☐ 4. The client's facial expressions become animated.

The Intrapartal Client with Risk Factors

76. A client is admitted with a suspected abruptio placentae. The nurse should assess the client for which signs and symptoms? Select all that apply.

- ☐ 1. bleeding that is concealed or apparent
- ☐ 2. abdominal rigidity
- ☐ 3. painful abdomen
- ☐ 4. painless bleeding
- ☐ 5. large placenta
- ☐ 6. bleeding that stops spontaneously

77. A 39-year-old multigravid client at 39 weeks' gestation admitted to the hospital in active labor has been diagnosed with class II heart disease. To ensure cardiac emptying and adequate oxygenation during labor, the nurse plans to encourage the client to:

- ☐ 1. breathe slowly after each contraction.
- ☐ 2. avoid the use of analgesics for the labor pain.
- ☐ 3. remain in a side-lying position with the head elevated.
- ☐ 4. request local anesthesia for vaginal birth.

78. When developing the plan of care for a multigravid client with class III heart disease, the nurse should expect to assess the client frequently for which problem?

- ☐ 1. dehydration
- ☐ 2. nausea and vomiting
- ☐ 3. iron deficiency anemia
- ☐ 4. tachycardia

79. A primigravid client at 39 weeks' gestation is admitted to the hospital for induction of labor. The healthcare provider (HCP) has prescribed prostaglandin E2 gel (dinoprostone) for the client. Before administering prostaglandin E2 gel to the client, which action should the nurse do **first**?

- ☐ 1. Assess the frequency of uterine contractions.
- ☐ 2. Place the client in a side-lying position.
- ☐ 3. Determine whether the membranes have ruptured.

- ☐ 4. Prepare the client for an amniotomy.

80. A primigravida near birth is experiencing a prolonged second stage of labor with a fetus suspected of weighing over 4 kg. Which intervention is **most** important?

- ☐ 1. preparing for a vacuum-assisted birth
- ☐ 2. administering an IV fluid bolus
- ☐ 3. preparing for an emergency cesarean birth
- ☐ 4. performing the McRoberts maneuver

81. A multigravid client is receiving oxytocin augmentation. When the client's cervix is dilated to 6 cm, her membranes rupture spontaneously with meconium-stained amniotic fluid. Which action should the nurse perform **first**?

- ☐ 1. Increase the rate of the oxytocin infusion.
- ☐ 2. Turn the client to a knee-to-chest position.
- ☐ 3. Assess cervical dilation and effacement.
- ☐ 4. Assess the fetal heart rate.

82. A multigravid client in active labor at 39 weeks' gestation has a history of smoking one to two packs of cigarettes daily. Which problem is the nurse **most** likely to find during the infant's assessment?

- ☐ 1. sedation
- ☐ 2. hyperbilirubinemia
- ☐ 3. low birth weight
- ☐ 4. hypocalcemia

83. A primigravid client who has had a prolonged labor but now is completely dilated has received epidural anesthesia. Which statement should the nurse include in the teaching plan about pushing?

- ☐ 1. The client needs to push for at least 1 to 3 minutes.
- ☐ 2. Pushing is most effective when the client holds her breath.
- ☐ 3. The client should be urged to push with an open glottis.
- ☐ 4. Pushing is limited to times when she feels the urge.

84. The healthcare provider (HCP) determines that outlet forceps are

needed to assist in the birth of a primigravid client in active labor with a large-for-gestational-size fetus. The nurse understands that the fetus's skull must be at what point before this procedure can take place?

- ☐ 1. It is engaged past the inlet.
- ☐ 2. It is at +1 station.
- ☐ 3. It is visible at the perineal floor.
- ☐ 4. It has reached the level of the ischial spines.

85. The healthcare provider (HCP) prescribes an amnioinfusion for a primigravid client at term who is diagnosed with oligohydramnios. The nurse explains to the client the primary purpose of this procedure is to:

- ☐ 1. decreases the frequency and severity of variable decelerations.
- ☐ 2. minimizes the possibility of fetal metabolic alkalosis.
- ☐ 3. increases the fetal heart rate accelerations during a contraction.
- ☐ 4. raises the amniotic fluid index to more than 15 cm.

86. The nurse is admitting a primigravid client at 37 weeks' gestation who has been diagnosed with preeclampsia to the labor and birth area. Which client care room is **most** appropriate for this client?

- ☐ 1. a brightly lit private room at the end of the hall from the nurses' station
- ☐ 2. a semiprivate room midway down the hall from the nurses' station
- ☐ 3. a private room with many windows that is near the operating room
- ☐ 4. a darkened private room as close to the nurses' station as possible

87. A multigravid client is admitted to the labor area from the emergency department. At the time of admission, the fetal head is crowning, and the client yells, "The baby is coming!" To help the client remain calm and cooperative during the imminent birth, which response by the nurse is **most** - appropriate?

- ☐ 1. "You are right; the baby is coming, so just relax."
- ☐ 2. "Please do not push because you will tear your cervix."
- ☐ 3. "Your healthcare provider will be here as soon as possible."
- ☐ 4. "I will explain what is happening to guide you as we go along."

88. The nurse is caring for a multigravid client and observes the woman squatting on the bed and the fetal head crowning. After calling for assistance

and helping the client lie down, which action should the nurse do **next**?

- ☐ 1. Tell the client to push between contractions.
- ☐ 2. Provide gentle support to the fetal head.
- ☐ 3. Apply gentle upward traction on the neonate's anterior shoulder.
- ☐ 4. Massage the perineum to stretch the perineal tissues.

89. During the first hour after a precipitous birth, the nurse should monitor a multiparous client for signs and symptoms of which complication?

- ☐ 1. postpartum "blues"
- ☐ 2. uterine atony
- ☐ 3. intrauterine infection
- ☐ 4. urinary tract infection

90. A multigravid client in labor at 38 weeks' gestation has been diagnosed with Rh sensitization and probable fetal hydrops and anemia. Which fetal heart rate pattern would the nurse find is **most** concerning?

- ☐ 1. early deceleration pattern
- ☐ 2. sinusoidal pattern
- ☐ 3. variable deceleration pattern
- ☐ 4. late deceleration pattern

91. The nurse in the labor and birth area receives a telephone call from the emergency department announcing that a multigravid client in active labor is being transferred to the labor area. The client has had no prenatal care. When the client arrives by stretcher, she says, "I think the baby is coming ... Help!" The fetal skull is crowning. The nurse should obtain which information **first**?

- ☐ 1. estimated date of birth
- ☐ 2. amniotic fluid status
- ☐ 3. gravida and parity
- ☐ 4. prenatal history

92. A multiparous client gives birth to dizygotic twins at 37 weeks' gestation. The twin neonates require additional hospitalization after the client is discharged. What is the **most** appropriate goal to include in the plan of care for the parents while the twins are hospitalized?

- ☐ 1. Discuss how they will cope with twin infants at home.

- ☐ 2. Participate in care of the twins as much as possible.
- ☐ 3. Take turns providing 24-hour observation of the twins.
- ☐ 4. Identify complications that may occur as the twins develop.

93. A primigravid client at 41 weeks' gestation is admitted to the hospital's labor and birth unit in active labor. After 25 hours of labor with membranes ruptured for 24 hours, the client gives birth to a healthy neonate vaginally with a midline episiotomy. Which problem should the nurse identify as the **priority** for the client?

- ☐ 1. activity intolerance
- ☐ 2. sleep deprivation
- ☐ 3. situational low self-esteem
- ☐ 4. risk for infection

94. The nurse is caring for a primiparous client and her neonate immediately after birth. The neonate was born at 41 weeks' gestation and weighs 9 lb (4,082 g). Assessing for signs and symptoms of which condition should be a **priority** in this neonate?

- ☐ 1. anemia
- ☐ 2. hypoglycemia
- ☐ 3. delayed meconium
- ☐ 4. elevated bilirubin

95. A multigravid client in active labor at term is diagnosed with polyhydramnios. The healthcare provider (HCP) has instructed the client about possible neonatal complications related to the polyhydramnios. The nurse determines that the client has understood the instructions when the client states that polyhydramnios is associated with which problem in the fetus or neonate?

- ☐ 1. renal dysfunction
- ☐ 2. intrauterine growth restriction
- ☐ 3. pulmonary hypoplasia
- ☐ 4. gastrointestinal disorders

96. A primigravid client at 39 weeks' gestation is admitted to the hospital in active labor. On admission, the client's cervix is 6 cm dilated. After 2

hours of active labor, the client's cervix is still dilated at 6 cm with 100% effacement at +1 station. Contractions are 3 to 5 minutes apart, lasting 45 seconds, and of moderate intensity. The nurse determines that the client is **most** likely experiencing which problem?

- ☐ 1. cephalopelvic disproportion
- ☐ 2. prolonged latent phase
- ☐ 3. prolonged transitional phase
- ☐ 4. hypotonic contraction pattern

97. The healthcare provider (HCP) who elects to perform a cesarean birth on a primigravid client for fetal distress has informed the client of possible risks during the procedure. When the nurse asks the client to sign the consent form, the client's husband says, "I will sign it for her. She is too upset by what is happening to make this decision." The nurse should:

- ☐ 1. ask the client if this is acceptable to her.
- ☐ 2. have the client and her husband both sign the consent form.
- ☐ 3. ask the client to sign the consent form.
- ☐ 4. ask the HCP to witness the consent form.

98. A multigravid client at term is admitted to the hospital for a trial labor and possible vaginal birth. She has a history of previous cesarean birth because of fetal distress. When the client is 4 cm dilated, she receives nalbuphine intravenously. While monitoring the fetal heart rate, the nurse observes minimal variability and a rate of 120 bpm. The nurse should explain to the client that the decreased variability is **most** likely caused by which factor?

- ☐ 1. maternal fatigue
- ☐ 2. fetal malposition
- ☐ 3. small-for-gestational-age fetus
- ☐ 4. effects of analgesic medication

99. During a scheduled cesarean birth of a primigravid client with a fetus at 39 weeks' gestation in a breech presentation, a neonatologist is present in the operating room. The nurse explains to the client that the neonatologist is present because neonates born by cesarean birth tend to have an increased incidence of which problem?

- ☐ 1. congenital anomalies
- ☐ 2. pulmonary hypertension
- ☐ 3. meconium aspiration syndrome
- ☐ 4. respiratory distress syndrome

100. A 28-year-old multigravid client at 28 weeks' gestation diagnosed with acute pyelonephritis is receiving intravenous fluids and antibiotics. After teaching the client about the rationale for the aggressive therapy, the nurse determines that the client needs further instruction when she says that acute pyelonephritis can lead to which complication?

- ☐ 1. preterm labor
- ☐ 2. maternal sepsis
- ☐ 3. intrauterine growth restriction
- ☐ 4. congenital fetal anomalies

101. A primigravid client at 38 weeks' gestation is admitted to the labor suite in active labor. The client's physical assessment reveals a chlamydial infection. The nurse explains that if the infection is left untreated, the neonate may develop which problem?

- ☐ 1. conjunctivitis
- ☐ 2. heart disease
- ☐ 3. harlequin sign
- ☐ 4. brain damage

102. A 34-year-old primigravid client at 39 weeks' gestation admitted to the hospital in active labor has type B Rh-negative blood. The nurse should instruct the client that if the neonate is Rh positive, the client will receive an Rh immune globulin (RHIG) injection for which reason?

- ☐ 1. to prevent Rh-positive sensitization with the next pregnancy
- ☐ 2. to provide active antibody protection for this pregnancy
- ☐ 3. to decrease the amount of Rh-negative sensitization for the next pregnancy
- ☐ 4. to destroy fetal Rh-positive cells during the next pregnancy

103. A 16-year-old primigravid client admitted at 38 weeks' gestation with severe preeclampsia is given intravenous magnesium sulfate and

lactated Ringer's solution. The nurse should obtain which information?

- ☐ 1. urinary output every 8 hours
- ☐ 2. deep tendon reflexes every 4 hours
- ☐ 3. respiratory rate every hour
- ☐ 4. blood pressure every 6 hours

104. The nurse has received a telephone call from the emergency department indicating that a multigravid client in early labor and diagnosed with probable placenta previa will be arriving soon. What is the **priority** intervention when the client arrives at the unit?

- ☐ 1. whole blood replacement
- ☐ 2. continuous blood pressure monitoring
- ☐ 3. internal fetal heart rate monitoring
- ☐ 4. an immediate cesarean birth

105. During admission, a multigravida in early active labor acts somewhat euphoric and tells the nurse that she smoked some crack cocaine before coming to the hospital. In addition to fetal heart rate assessment, the nurse should monitor the client for symptoms of which complication?

- ☐ 1. placenta previa
- ☐ 2. ruptured uterus
- ☐ 3. maternal hypotension
- ☐ 4. abruptio placentae

106. A primigravid client in early labor tells the nurse that she was exposed to rubella at about 14 weeks' gestation. After birth, the nurse should assess the neonate for which complication?

- ☐ 1. hydrocephaly
- ☐ 2. cardiac disorders
- ☐ 3. renal disorders
- ☐ 4. bulging fontanelles

107. A primigravid client in early labor with abruptio placentae develops disseminated intravascular coagulation (DIC). Which agent should the nurse expect the healthcare provider (HCP) to prescribe?

- ☐ 1. magnesium sulfate

- ☐ 2. warfarin sodium
- ☐ 3. fresh frozen platelets
- ☐ 4. meperidine hydrochloride

108. A multigravid client diagnosed with chronic hypertension is now in preterm labor at 32 weeks' gestation. The healthcare provider (HCP) has prescribed magnesium sulfate at 3 g/h. Which assessment finding indicates that the intended therapeutic effect has occurred?

- ☐ 1. decrease in fetal heart rate accelerations
- ☐ 2. decrease in the frequency and number of contractions
- ☐ 3. decrease in maternal blood pressure rate
- ☐ 4. decrease in maternal respiratory rate

109. A primigravid client who was successfully treated for preterm labor at 30 weeks' gestation had a history of mild hyperthyroidism before becoming pregnant. What instructions should the nurse include in the plan of care?

- ☐ 1. Continue taking low-dose oral propylthiouracil as prescribed.
- ☐ 2. Discontinue taking the methimazole until after the birth of the neonate.
- ☐ 3. Consider breast-feeding the neonate after the birth.
- ☐ 4. Contact the healthcare provider (HCP) if bradycardia occurs.

110. A primigravid client at 37 weeks' gestation has been hospitalized for several days with severe preeclampsia. While caring for the client, the nurse observes that the client is beginning to have a seizure. Which action should the nurse do **first**?

- ☐ 1. Pad the side rails of the client's bed.
- ☐ 2. Turn the client to the right side.
- ☐ 3. Insert a padded tongue blade into the client's mouth.
- ☐ 4. Call for immediate assistance in the client's room.

111. While assessing a primigravid client admitted at 36 weeks' gestation, the nurse observes multiple bruises on the client's face, neck, and abdomen. When asked about the bruises, the client admits that her boyfriend beats her now and then and says, "I want to leave him because I am afraid he will hurt the baby." Which action is the nurse's **most** appropriate response?

- ☐ 1. Tell the client to leave the boyfriend immediately.
- ☐ 2. Ask the client when she last felt the baby move.
- ☐ 3. Refer the client to a social worker for possible options.
- ☐ 4. Report the incident to the unit nursing supervisor.

112. A multigravid client in active labor at term suddenly sits up and says, “I cannot breathe! My chest hurts really bad!” The client’s skin begins to turn a dusky gray color. After calling for assistance, which action should the nurse take **next**?

- ☐ 1. Administer oxygen by face mask.
- ☐ 2. Begin cardiopulmonary resuscitation.
- ☐ 3. Administer intravenous oxytocin.
- ☐ 4. Obtain a prescription for intravenous fibrinogen.

Managing Care, Quality, and Safety for Clients Giving Birth

113. A newly postpartum client is asking to go to the bathroom 45 minutes after childbirth. She had an epidural for labor and birth and has an IV infusing, and every 15 minutes assessments are in progress. To provide the safest care for this client, the nurse should:

- ☐ 1. ask her to remain in bed until the 15-minute assessments are complete.
- ☐ 2. assess client’s ability to stand and bear weight before going to the bathroom.
- ☐ 3. encourage the client to sit at the side of the bed before ambulating to the bathroom.
- ☐ 4. ask the client to ambulate the first time with a staff member at her side.

114. The charge nurse is preparing for the day shift on the labor and birth unit. Which would be included in the responsibilities for this position? Select all that apply.

- ☐ 1. Review the current status of each labor client with the primary nurse.
- ☐ 2. Admit the new labor client sent from the triage area.
- ☐ 3. Complete the work of the nurse who had to leave 30 minutes early.
- ☐ 4. Follow up with the primary nurse after a birth.

- ☐ **5.** Complete report of unit with the oncoming charge nurse.

115. The labor and birth nurse is assigned to triage for the day. There are four clients already in rooms, and reports have been received about each of these clients. To provide the safest care and best manage time, the nurse should plan to see which client **first**?

- ☐ **1.** a primipara in active labor at 5 cm asking to be admitted and wanting an epidural
- ☐ **2.** a primipara who is 100% effaced, 8 cm dilated, +2 station with nausea
- ☐ **3.** a client with no prenatal care, occasional contractions, BP 148/90 mm Hg, and swollen feet
- ☐ **4.** a client who is at 42 weeks' gestation with bloody show, no contractions, rupture of membranes 1 hour ago leaking green fluid

116. The triage nurse is giving a telephone report to the receiving nurse in the labor and birth unit. The multigravida client is 8 cm dilated and is being transferred to the labor and birth unit. How should the labor and birth nurse manage the next 10 minutes with the client? Select all that apply.

- ☐ **1.** Begin fetal monitoring.
- ☐ **2.** Call other staff to set up the birthing table.
- ☐ **3.** Assess comfort needs of the client.
- ☐ **4.** Determine support systems for the client.
- ☐ **5.** Prepare to give an early report to the nurse arriving on the next shift.

117. A client has experienced a postpartum hemorrhage. The healthcare provider (HCP) verbally prescribed carboprost tromethamine 0.25 mg IM stat at the time of the hemorrhage, and this was given by the nurse. The HCP put a prescription into the medical record for 0.25 mg carboprost tromethamine IV stat. When seeing the prescription, how should the nurse administering the carboprost tromethamine respond?

- ☐ **1.** Ask the charge nurse to have a discussion with the HCP about the prescription.
- ☐ **2.** Initiate an incident report.
- ☐ **3.** Call the HCP, discuss the prescription, and request revision if heard correctly.
- ☐ **4.** Wait until the HCP returns to the unit, and discuss the situation in

person.

118. The nurse is asked to develop an in-service to explain documents guiding professional nursing practice on the obstetrical unit. One of the documents included is the Code of Ethics. The nurse correctly explains that the Code of Ethics asks nurses to demonstrate which behaviors? Select all that apply.

- ☐ 1. Maintain the integrity of practice and shape social policy.
- ☐ 2. Develop, maintain, and improve healthcare environments.
- ☐ 3. Ask the hospital systems for fair compensation for work.
- ☐ 4. Be responsible and accountable for individual practice.
- ☐ 5. Increase professional competence and personal growth.

119. The nurse is preparing to assist the healthcare provider (HCP) with a cervical check for a client whose membranes have ruptured. What equipment should the nurse have ready for the midwife? Select all that apply.

- ☐ 1. sterile speculum
- ☐ 2. sterile gloves
- ☐ 3. sterile lubricant
- ☐ 4. amnio hook
- ☐ 5. cervical dilators

120. Which client is the **best** candidate for a vaginal birth after a caesarean (VBAC)?

- ☐ 1. client who had an emergency caesarean section because of fetal distress during her last delivery and has a classic incision
- ☐ 2. client who had a breech presentation in her last pregnancy, and this pregnancy is a vertex pregnancy
- ☐ 3. client who dilated 6 cm in her last birth and failed to progress beyond this point despite 5 more hours of labor
- ☐ 4. diabetic client whose last infant was over 10 lb (4.5 kg). This infant is larger, as seen on ultrasound.

Answers, Rationales, and Test-Taking Strategies

*The answers and rationales for each question follow below, along with keys (🔑) to the client need (CN) and cognitive level (CL) for each question. In addition, you will also see a glossary icon (📖) highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 12–23 and pages 35–36 in Part 1 of this book.*

The Primigravid Client in Labor

1. 3. The nurse should monitor anesthesia/pain levels every 30 minutes during active labor to ascertain that this client is comfortable during the labor process and particularly during active labor when pain often accelerates for the client. When in active labor, oxygen saturation is not monitored unless there is a specific need, such as heart disease. The client should not be on her back but wedged to the right or left side to take the pressure off the vena cava. When lying on the back, the fetus compresses the major blood vessels. Vaginal bleeding in active labor should be monitored every 30 minutes to 1 hour.

🔑 CN: Reduction of risk potential; CL: Create

2. 2. The first stage of labor is categorized into three phases: latent, active, and transition. During the active stage of labor, intermittent fetal monitoring is performed every 30 minutes to detect changes in fetal heart rate such as bradycardia, tachycardia, or decelerations in a low-risk labor. If complications develop, more frequent or continuous electronic fetal monitoring may be needed. During the latent phase, intermittent monitoring is usually performed every 1 hour because contractions during this time are usually less frequent. During the transition phase, intermittent monitoring is performed every 5 minutes because the client is getting closer to the birth of the baby. Pushing occurs in stage II of labor, and monitoring continues to occur every 5 to 15 minutes.

🔑 CN: Reduction of risk potential; CL: Analyze

3. 3. The urge to push is often present when the fetus reaches + stations. This client does not have a cervix that is completely dilated, and pushing in this situation may tear the cervix. Encouraging the client to breathe through the urge to push is the most appropriate strategy and allows the cervix to dilate before pushing. Increasing the level of the epidural is inappropriate as nursing would like to have the client be able to push when she is fully dilated. Comfort measures are important for the client at this time but are not the highest priority for the nurse.

 CN: Management of care; CL: Synthesize

4. 2. Assessment findings indicate that the client is in the transition phase of labor. During this phase, it is not unusual for clients to exhibit a loss of control or irritability. Leg tremors, nausea, vomiting, and an urge to bear down also are common. Excitement is associated with the latent phase of labor. Numbness of the legs may occur when epidural anesthesia has been given; however, it is rare when no anesthesia is given. Feelings of relief generally occur during the second stage, when the client begins bearing-down efforts.

 CN: Health promotion and maintenance; CL: Analyze

5. 1. This figure shows the client's baby in a breech presentation with the baby facing the pelvis on the left, the sacrum as the presenting part, and the presenting part (sacrum) is posterior in the pelvis. Figure 2 shows a vertex presentation with the baby in a left occipitoanterior (LOA) position. Figure 3 shows a vertex presentation, left occipitoposterior (LOP). Figure 4 shows a face position with the baby in a left mentotransverse (LMT) position.

 CN: Physiological adaptation; CL: Synthesize

6. 1,3,4,6. Effleurage is a method of light massage that can provide pain relief. Guided imagery is a relaxation technique used in birth preparation, as is pattern-paced breathing. Positive reinforcement is not a labor support method, nor is self-containment theory.

CN: Basic care and comfort; CL: Synthesize

7. 1. Nitrazine paper responds to alkaline fluids by changing blue; amniotic fluid is alkaline so the color verifies that the membranes are ruptured. The nurse notifies the provider that membranes are ruptured so that a plan of action can be developed. Rupture of membranes in the absence of labor increases the risk of infection. Vaginal examinations are limited until labor is initiated. Wearing a sanitary pad increases potential for infection. Documentation of the nitrazine test is completed after notifying the provider.

CN: Reduction of risk potential; CL: Apply

8. 3. Prostaglandin gel may be used for cervical ripening before the induction of labor with oxytocin. It is usually administered by catheter or suppository, or by vaginal insertion. Two to three doses are usually needed to begin the softening process. Common adverse effects include nausea, vomiting, fever, and diarrhea. Continuous fetal heart rate monitoring and

close monitoring of maternal vital signs are necessary to detect subtle changes or adverse effects. Prostaglandin gel usually does not initiate contractions; therefore, the rest period between contractions will be > 2 minutes. There is no need to assess reflexes based on prostaglandin use. Leaking of amniotic fluid is not caused by the use of this gel.

CN: Pharmacological and parenteral therapies; CL: Evaluate

9. 1. External cephalic version is the turning of the fetus from a breech position to the vertex position to prevent the need for a cesarean birth. Gentle pressure is used to rotate the fetus in a forward direction to a cephalic lie. Contraindications to the procedure include multiple gestation because of the potential for fetal injury or uterine injury, severe oligohydramnios (decreased amniotic fluid), contraindications to a vaginal birth (e.g., cephalopelvic disproportion), and unexplained third-trimester bleeding. If the mother has Rh-negative blood type, the procedure can be performed, and Rh immunoglobulin should be administered in case minimal bleeding occurs. A history of gestational diabetes is not a contraindication unless the fetus is large for gestational age and the client has cephalopelvic disproportion.

CN: Reduction of risk potential; CL: Analyze

10. 2. The goal of oxytocin administration in labor augmentation is to establish an adequate contraction pattern to enhance the forces of labor. The expected outcome is a pattern of contractions occurring every 2 to 3 minutes, lasting 40 to 60 seconds, of moderate intensity with a palpable resting tone between contractions. Other contraction patterns will cause the cervix to dilate too quickly or too slowly. Cervical changes in softening, effacement, and moving to an anterior position are associated with use of cervical ripening agents, such as prostaglandin gel. Cervical dilation of 2 cm/h is too rapid for the induction/augmentation process.

CN: Pharmacological and parenteral therapies; CL: Evaluate

11. 4. Anatomically, the best position for the client to assume is the squatting position because this enhances pelvic diameters and allows gravity to assist in the expulsion stage of labor. This position also provides for natural pressure anesthesia as the fetal presenting part presses on the stretched perineum. If the client is extremely fatigued from a lengthy labor

process, she may prefer the dorsal recumbent position. However, this position is not considered the best position anatomically. The lithotomy position may be ineffective and uncomfortable for a client who is ready to push. The hands and knees position may help to alleviate some back pain. However, this position can cause discomfort to the arms and wrists and is tiring over a long period of time.

CN: Health promotion and maintenance; CL: Apply

12. 4. During transition, contractions are increasing in frequency, duration, and intensity. The most appropriate nursing problem is pain related to strength and duration of the contractions. Insufficient information is provided in the scenario to support the other listed nursing diagnoses. Urinary retention would be appropriate if the client had a full bladder and was unable to void. Hyperventilation might apply if client was breathing too rapidly, but there is no evidence this is occurring. Ineffective coping might apply if the client said, “I cannot do this” or something similar.

CN: Health promotion and maintenance; CL: Analyze

13. 1. The most reliable sign that the placenta has detached from the uterine wall is lengthening of the cord outside the vagina. Other signs include a sudden gush of (rather than a decrease in) vaginal blood. Usually, when placenta detachment occurs, the uterus becomes more firm and changes in shape from discoid to globular. This process takes about 5 minutes. If the placenta does not separate, manual removal may be necessary to prevent postpartum hemorrhage.

CN: Health promotion and maintenance; CL: Analyze

14. 3. Birth is a very emotional experience. An expression of happiness with tears is a normal reaction. Cultural factors, exhaustion, and anxieties over the new role can all affect maternal responses, so the nurse must be sensitive to the client’s emotional expressions. There is no evidence to suggest that the mother is disappointed in the baby’s gender, grieving over the end of the pregnancy, or a candidate for postpartum “blues.” However, approximately 80% of postpartum clients experience transient postpartum blues several days after childbirth.

CN: Health promotion and maintenance; CL: Analyze

15. 3. Most authorities suggest that a woman in an early stage of labor should be allowed to walk if she wishes as long as no complications are present. Birthing centers and single-room maternity units allow women considerable latitude without much supervision at this stage of labor. Gravity and walking can assist the process of labor in some clients. If the client becomes tired, she can rest in bed in the left lateral recumbent position or sit in a comfortable chair. Resting in the left lateral recumbent position improves circulation to the fetus.

CN: Health promotion and maintenance; CL: Synthesize

16. 1. Birth educators use various techniques and methods to prepare parents for labor and birth. Active relaxation involves relaxing uninvolved muscle groups while contracting a specific group and using chest breathing techniques to lift the diaphragm off the contracting uterus. A deep, meditative, sleep-like state is a form of passive relaxation. Focusing on an object in the room is part of Lamaze technique for distraction. Breathing rapidly and deeply can lead to hyperventilation and is not recommended.

CN: Health promotion and maintenance; CL: Synthesize

17. 3. Light stroking of the skin, or *effleurage*, is commonly used with the Lamaze method of birth preparation. Light abdominal massage with just enough pressure to avoid tickling is thought to displace the pain sensation during a contraction. Deep kneading and secure grasping are typically associated with relaxation massages to relieve stress. Prolonged pressure on specific sites is associated with acupressure.

CN: Health promotion and maintenance; CL: Apply

18. 1. Some **healthcare providers (HCPs)**  do not allow clients with ruptured membranes to use a hot tub or jet hydrotherapy tub during labor for fear of infections. The temperature of the water should be between 98°F and 100°F (36.7°C and 37.8°C) to prevent hyperthermia. Jet hydrotherapy is not contraindicated for clients with multifetal gestation, diabetes mellitus, or hypotonic labor patterns.

CN: Reduction of risk potential; CL: Synthesize

19. 4. To determine fetal lung maturity, the sample of amniotic fluid will

be tested for the L/S ratio. When fetal lungs are mature, the ratio should be 2:1. Bilirubin indicates hemolysis and, if present in the fluid, suggests Rh disease. Red blood cells should not appear in the amniotic fluid because their presence suggests fetal bleeding. Barr body determination is a chromosome analysis of the sex chromosomes that is sometimes used when a child is born with ambiguous genitalia.

CN: Health promotion and maintenance; CL: Analyze

20. 3. Pushing during the first stage of labor, when the urge is felt but the cervix is not completely dilated, may produce cervical swelling, making labor more difficult. The client should be encouraged to use a pant-blow (or blow-blow) pattern of breathing to help overcome the urge to push. The McDonald procedure is used for cervical cerclage for an incompetent cervix and is inappropriate here. Increasing the rate of oxygen and intravenous fluids will not alleviate the pressure that the client is feeling. The client should not push even if she feels the urge to do so because this may result in cervical edema at 7-cm dilation.

CN: Health promotion and maintenance; CL: Synthesize

21. 4. The client is in the transition phase of the first stage of labor. During this phase, the client needs encouragement and support because this is a difficult and painful time, when contractions are especially strong. Usually, the client finds it difficult to maintain self-control. Everything else seems secondary to her as she progresses into the second stage of labor. Although ice chips may be given, typically the client does not desire sips of water. Labor is hard work. Generally, the client is perspiring and does not desire additional warmth. Frequent perineal cleansing is not necessary unless there is excessive amniotic fluid leaking.

CN: Health promotion and maintenance; CL: Synthesize

22. 1. The sagittal suture is the most readily felt during a vaginal examination. When the fetus is in the LOA position, the occiput faces the mother's left. The lambdoid suture is on the side of the skull. The coronal suture is a horizontal suture across the front portion of the fetal skull that forms the anterior fontanelle. It may be felt with a brow presentation. The frontal suture may be felt with a brow or face presentation.

CN: Health promotion and maintenance; CL: Apply

23. 2. Molding occurs with vaginal births and is commonly seen in newborns. This is especially true with primigravid clients experiencing a lengthy labor process. Parents need to be reassured that it is not permanent and that it typically lasts a day or two before resolving. Molding rarely is present if the fetus is in a breech or brow presentation. Surgical intervention is not necessary.

CN: Health promotion and maintenance; CL: Create

24. 1,2,5,6. Uterine inversion is indicated by a sudden gush of blood from the vagina leading to decreased blood pressure, and an inability to palpate the uterus since it may be in or protruding from the vagina, and any signs of blood loss such as diaphoresis, paleness, or dizziness could be observed at this time. Intense pain and a hard contracting uterus are not associated with uterine inversion.

CN: Reduction of risk potential; CL: Analyze

25. 2. Avoidance, hostility, or low-key (passive) behavior toward the baby may be a cue to potential bonding problems. The nurse should encourage the client to give the baby the first feeding to begin the bonding process. Expressions of disappointment with the baby's gender may also signal problems with maternal-infant bonding. Comparing the baby's features to her own indicates identification of the neonate as belonging to her, suggesting bonding with neonate. Comparing the actual neonate with the "fantasized neonate" is a normal maternal reaction. Wanting to buy a blue outfit indicates an interest in and connection with the neonate and is a sign of bonding.

CN: Reduction of risk potential; CL: Analyze

26. 1. According to the gate-control theory of pain, a closed gate means that the client should feel no pain. The gate-control theory of pain refers to the gate-control mechanisms in the substantia gelatinosa that are capable of halting an impulse at the level of the spinal cord so the impulse is never perceived at the brain level as pain (i.e., a process similar to keeping a gate closed).

CN: Health promotion and maintenance; CL: Evaluate

27. 4. The bladder status should be monitored throughout the labor process, but especially before the client begins pushing. A full bladder can impede the progress of labor and slow fetal descent. Because she has had an epidural anesthetic, it is most likely that the client is receiving intravenous fluids, contributing to a full bladder. The client also does not feel the urge to void because of the anesthetic. Although it is important to monitor membrane status and fetal heart rate variability throughout labor, this does not affect the client's ability to push. There is no need to recheck cervical dilation because increasing the frequency of examinations can increase the client's risk for infection.

CN: Reduction of risk potential; CL: Analyze

28. 1. The normal length of the latent stage of labor in a primigravid client is 6 hours. If the client is having prolonged labor, the nurse should monitor the client for signs of exhaustion as well as dehydration. Hypotonic contractions, which are painful but ineffective, may be occurring. Oxytocin augmentation may be necessary. Chills and fever are manifestations of an infection and are not associated with a prolonged latent phase of labor. Fluid overload can occur from rapid infusion of intravenous fluids administered if the client is experiencing hemorrhage or shock. It is not associated with prolonged latent phase. The client's membranes are intact, so it would be difficult to assess meconium staining of the fluid. Meconium-stained fluid is associated with fetal distress, and this fetus appears to be in a healthy state, as evidenced by a fetal heart rate within normal range and good variability.

CN: Reduction of risk potential; CL: Analyze

29. 1. The client who has back pain during labor experiences marked discomfort because the fetus is in an LOP position. This pain is much greater than when the fetus is in the anterior position because the fetal head impinges on the sacrum in the course of rotating to the anterior position. Application of firm pressure to the sacral area can help alleviate the pain. Problems of severe back pain during labor do not typically require a cesarean birth. The **healthcare provider (HCP)**  may elect to do an episiotomy, but it is not necessarily required. It is unlikely that a primigravid client with a fetus in an LOP position will have a precipitous birth; rather, labor is usually more prolonged. A hands-and-knees position or a right side-lying position may

help to rotate the fetal head and thus alleviate some of the back pain.

CN: Health promotion and maintenance; CL: Synthesize

30. 1. The psychoprophylaxis method of birth suggests using slow chest breathing until it becomes ineffective during labor contractions, then switching to shallow chest breathing (mostly at the sternum) during the peak of a contraction. The rate is 50 to 70 breaths/min. Deep chest breathing is appropriate for the early phase of labor, in which the client exhibits less frequent contractions. When transition nears, a rapid pant-blow pattern of breathing is used. Slow abdominal breathing is very difficult for clients in labor.

CN: Health promotion and maintenance; CL: Apply

31. 3. Fetal scalp stimulation is commonly prescribed when there is decreased fetal heart rate variability. Pressure is applied with the fingers to the fetal scalp through the dilated cervix. This should cause a tactile response in the fetus and increase the fetal heart rate and variability. However, if the fetus is in distress and becoming acidotic, fetal heart rate acceleration will not occur. The fetal hematocrit level can be measured by fetal blood sampling. Scalp stimulation does not increase the strength of the contractions. However, it can increase fetal heart rate and variability. Fetal position is assessed by identifying skull landmarks (sutures) during a vaginal examination.

CN: Reduction of risk potential; CL: Apply

32. 3. When a client has severe back pain during labor, the fetus is most likely in an occipitoposterior position. This means that the fetal head presses against the client's sacrum, causing marked discomfort during contractions. These sensations may be so intense that the client requests medication for relief of the back pain rather than the contractions. Breech presentation and transverse lie are usually known prior to 8-cm dilation and a cesarean section is performed. Fetal occiput anterior position does not increase the pain felt during labor.

CN: Health promotion and maintenance; CL: Apply

33. 1,3,5. Decelerations alert the nurse that the fetus is experiencing decreased blood flow from the placenta. Administering oxygen will increase

tissue perfusion. Placing the mother on her side will increase placental perfusion and decrease cord compression. Using an internal fetal monitor would help in identifying the possible underlying cause of the decelerations, such as metabolic acidosis. Assessing for pain relief and readjusting the monitor would have no effect on correcting the late decelerations.

CN: Reduction of risk potential; CL: Synthesize

34. 3. The third maneuver involves grasping the lower portion of the abdomen just above the symphysis pubis between the thumb and index finger. This maneuver determines whether the fetal presenting part is engaged. The first maneuver involves facing the woman's head and using the tips of the fingers to palpate the uterine fundus. This maneuver is used to identify the part of the fetus that lies over the inlet to the pelvis. The second maneuver involves placing the palms of each hand on either side of the abdomen to locate the back of the fetus. The fourth maneuver involves placing the fingers on both sides of the uterus and pressing downward and inward in the direction of the birth canal. This maneuver is done to determine fetal attitude and degree of extension and should only be done if the fetus is in the cephalic presentation.

CN: Physiological adaptation; CL: Apply

35. 1. Leopold's maneuvers are performed to determine the presentation and position of the fetus. The third maneuver determines whether the fetal presenting part is engaged in the maternal pelvis. The first maneuver distinguishes between a breech and a cephalic presentation through palpation of the top of the fundus. The second maneuver locates the fetal back, arms, and legs. The fetal heart rate monitoring device should be placed near the fetal skull and back for optimal fetal heart rate monitoring. The fourth maneuver is done to locate the fetal cephalic prominence if the fetus is in a cephalic position.

CN: Health promotion and maintenance; CL: Apply

The Multigravid Client in Labor

36. 4. Epidurals are given when labor is established, usually at 3- to 4-cm dilation. The effect of the epidural should be that labor will continue and not

be slowed down by the administration of the epidural. The use of an epidural is not correlated with rupture of membranes. The contraction pattern for this client is adequate, not slow, and considered normal for 2-cm dilation. Epidurals are given at 3- to 4-cm dilation, and if there is medication available, it can be given to make the client comfortable until an epidural can be given.

 CN: Management of care; CL: Apply

37. 1,2,4,5. A multiparous client usually gives birth within 12 hours of the time labor began. The pushing phase statistically takes 30 minutes or less and many multiparous clients go immediately from 10-cm dilation to birth. Contractions become regular and increase in frequency, intensity, and duration as labor progresses for both primiparous and multiparous clients. Transition will be shorter for a multiparous client than it will for a primiparous client, as the entire labor process takes less time for someone who has had a baby before. This client will withdraw into herself during transition, and this is a common characteristic for those in the transition phase.

 CN: Management of care; CL: Create

38. 3. The cause of variable decelerations is cord compression, which may be relieved by moving the client to one side or another. If the client is already on the left side, changing the client to the right side is appropriate. Performing a vaginal examination will let the nurse know how far dilated the client is but will not relieve the cord compression. If the decelerations are not relieved by position changes, oxygen should be initiated, but the rate should be 8 to 10 L/min. Notifying the **HCP**  should occur if turning the client and administering oxygen does not relieve the decelerations.

 CN: Management of care; CL: Synthesize

39. 1,2,4,5. Knowledge of how the fetus is tolerating contractions as well as the frequency, intensity, and duration of contractions, as indicated on the fetal monitor strip, are extremely important. The type of analgesia or anesthesia being used, the client's response, and her pain rating should be included as well. The amount of vaginal bleeding indicates whether this labor is in the normal range. The support persons with the client are an integral part

of the labor process and greatly influence how she manages labor emotionally and, commonly, physically. A complete change-of-shift report would include the client's name, age, gravida and parity, current and prior illnesses that may influence this hospitalization, prior labor and birth history if applicable, last vaginal examination time and findings, vaginal bleeding, support persons with the client, current IVs and other medications being used, and pertinent laboratory test results. Previous use of birth control is not important at this time.

 CN: Physiological adaptation; CL: Create

40. 2. The feeling of needing to have a bowel movement is commonly caused by pressure on the receptors low in the perineum when the fetal head is creating pressure on them. This feeling usually indicates advances in fetal station and that the client may be close to birth. The nurse should respond initially to the client's signs and symptoms by checking to validate current effacement, dilation, and station. If the fetus is ready to be born, having the room ready for the birth and having naloxone available are important. Naloxone completely or partially reverses the effects of natural and synthetic opioids, including respiratory depression. Documenting pain relief takes time away from the vaginal examination, preparing for birth, and obtaining naloxone. The birth may be occurring rapidly. Being prepared for the birth is a higher priority than documentation for this client.

 CN: Safety and infection control; CL: Synthesize

41. 2. Naloxone would not be used in a client who has a history of drug addiction. Naloxone would abruptly withdraw this woman from the drug she is addicted to as well as the nalbuphine. The withdrawal would occur within a few minutes of injection and, if severe enough, could jeopardize the mother and fetus. Lidocaine is a local anesthetic and numbs rather than decreases the effects of nalbuphine. The local anesthetic and the pudendal block are both appropriate for this birth but are used to numb the maternal perineum for birth.

 CN: Pharmacological and parenteral therapies; CL: Synthesize

42. 1. When a client receives an epidural anesthetic, sympathetic nerves are blocked along with the pain nerves, possibly resulting in vasodilation and

hypotension. Other adverse effects include bladder distention, prolonged second stage of labor, nausea and vomiting, pruritus, and delayed respiratory depression for up to 24 hours after administration. Diaphoresis and tremors are not usually associated with the administration of epidural anesthesia. Headache, a common adverse effect of many drugs, also is not associated with administration of epidural anesthesia.

CN: Pharmacological and parenteral therapies; CL: Analyze

43. 4. The fetal monitor strip shows late decelerations. The first intervention would be to turn off the oxytocin because the medication is causing the contractions. The stress caused by the contractions demonstrates that the fetus is not being perfused during the entire contraction (as shown by the late decelerations). There is no time to continue to observe in this situation; intervention is a priority. The client is attached to an internal fetal monitor, which would be possible only if her membranes had already ruptured. If the fetus continues to experience stress, fetal oximetry may be initiated.

CN: Physiological adaptation; CL: Analyze

44. 4. After an emergency birth, the nurse suggests that the mother begin breast-feeding to contract the uterus. Breast-feeding stimulates the natural production of oxytocin. In a multiparous client, uterine atony is a potential complication because of the stretching of the uterine fibers following each subsequent pregnancy. Although breast-feeding does help to begin the parental-infant bonding process, this is not the primary reason for the nurse to suggest breast-feeding. Prevention of neonatal hypothermia is accomplished by placing blankets on both the neonate and the mother. Although colostrum in breast milk provides the neonate with nutrients and immunoglobulins, the primary reason for breast-feeding is to stimulate the natural production of oxytocin to contract the uterus.

CN: Reduction of risk potential; CL: Apply

45. 3. A chill shortly after birth is a common, normal occurrence. Warm blankets can help provide comfort for the client. It has been suggested that the shivering response is caused by a difference between internal and external body temperatures. A different theory proposes that the woman is reacting to

fetal cells that have entered the maternal bloodstream through the placental site. Assessing the client's pulse rate will provide no further information about the chill. Decreasing the IV rate will not influence the length of time the client trembles. Assessing blood loss is a standard of care at this point postpartum but has no correlation with the chill.

CN: Health promotion and maintenance; CL: Synthesize

46. 2. After an amniotomy, the nurse should plan to first assess the FHR for 1 full minute. One of the complications of amniotomy is cord compression and/or prolapsed cord, and an FHR of 100 bpm or less should be promptly reported to the **HCP**.  A cord prolapse requires prompt birth by cesarean section. The client's contraction pattern should be monitored once labor has been established. The client's temperature, pulse, and respirations should be assessed every 2 to 4 hours after rupture of the membranes to detect an infection. The nurse should document the color, quantity, and odor of the amniotic fluid, but this can be done after the FHR is assessed and a normal pattern is present.

CN: Health promotion and maintenance; CL: Synthesize

47. 1. Nursing care for this client includes providing support, preparing for birth, assessing for potential complications, and providing for care of the newborn. Turning on the warmer is the best choice for providing for the care of the newborn. Oxygen and IV fluids may be indicated if variable or late decelerations are noted on the fetal heart monitor, but decelerations are not indicated in the question. It is likely too late for pharmacologic pain relief for a multigravid client. Education regarding care of the newborn is not appropriate at this time.

CN: Management of care; CL: Apply

48. 1. Breech presentations account for 5% of all births, and the most common is frank breech. In frank breech, there is flexion of the fetal thighs and extension of the knees. The feet rest at the side of the fetal head. In complete breech, there is flexion of the fetal thighs and knees; the fetus appears to be squatting. Footling breech occurs when there is an extension of the fetal knees and one or both feet protrude through the cervix. Vertex presentation occurs in 95% of births with the head engaged in the pelvis.

CN: Physiological adaptation; CL: Apply

49. 4. The nurse should assess the client's cervical dilation and station because the client's symptoms are indicative of the transition phase of labor. Multiparous clients can proceed 5 to 9 cm/h during the active phase of labor. Warming the temperature of the room is not helpful because the client will soon be ready to begin expulsive pushing. Increasing the intravenous fluid rate is not warranted unless the client is experiencing dehydration. Administration of an antiemetic at this point in labor is not warranted and may result in neonatal depression should a rapid birth occur.

CN: Health promotion and maintenance; CL: Synthesize

50. 4. To assess the frequency of the client's contractions, the nurse should assess the interval from the beginning of one contraction to the beginning of the next contraction. The duration of a contraction is the interval between the beginning and the end of a contraction. The acme identifies the peak of a contraction.

CN: Health promotion and maintenance; CL: Analyze

51. 3,4,5. The range of fetal heart rate fluctuating more than 25 beats per minutes could indicate fetal distress. The green peripad fluid indicates meconium, which could be associated with fetal distress. Increased fetal activity during labor may also indicate distress. The maternal vital signs noted and a perineal pad with blood and mucus are normal findings.

CN: Reduction of risk potential; CL: Analyze

52. 3. After spontaneous rupture of the amniotic fluid, the gushing fluid may carry the umbilical cord out of the birth canal. Sudden deceleration of the fetal heart rate commonly signifies cord compression and/or prolapse of the cord, which would require immediate birth. This client is particularly at risk because the fetus is preterm and the fetal head may not be engaged. Turning the client to the right side is not a priority action. However, changing the client's position would be appropriate if variable decelerations are present. The nurse should assess the color, amount, and odor of the fluid, but this can be done once the fetal heart rate is assessed and no problems are detected. Cervical dilation should be checked but only after the fetal heart

rate pattern is assessed.

CN: Reduction of risk potential; CL: Synthesize

53. 3,6. The pressure from the fetus descending into the birth canal can cause the client to feel she needs to move her bowels and could be near childbirth. Failure to assess the stage of labor and degree of fetal descent before allowing the client to go to the bathroom may lead to progression of labor and could result in a birth in the bathroom. Applying a fetal monitor may reassure the nurse that the fetus is doing well; however, it does not help to determine if the fetus is ready to be born, which is the higher priority in this situation. Regardless of the client's prior experience with back labor pain, the fetal head moving lower into the birth canal causes pressure in the lower back area similar to the feeling of pressure with a bowel movement.

CN: Safety and infection control; CL: Synthesize

54. 2. Spinal anesthesia is used less commonly today because of preference for epidural block anesthesia. One of the adverse effects of spinal anesthesia is a “spinal headache” caused by leakage of spinal fluid from the needle insertion. This can be treated by applying a cool cloth to the forehead, keeping the client in a flat position, or using a blood patch that can clot and seal off any further leakage of fluid. Spinal anesthesia is administered with the client in a sitting position or side lying. Another adverse effect of spinal anesthesia is hypotension caused by vasodilation. General anesthesia provides immediate anesthesia, whereas the full effects of spinal anesthesia may not be felt for 20 to 30 minutes. General anesthesia can be discontinued quickly when the anesthesiologist administers oxygen instead of nitrous oxide. Epidural anesthesia may take 1 to 2 hours to wear off.

CN: Pharmacological and parenteral therapies; CL: Evaluate

55. 3. Cimetidine is prescribed by some anesthesiologists who will be giving a general anesthetic to reduce the level of acid in the stomach contents, altering the pH to reduce the risk of complications should aspiration of vomitus occur. Aspiration of vomitus is the fifth most common cause of maternal mortality. Most anesthesiologists insert an endotracheal tube to reduce the incidence of aspiration. Isoproterenol is used to decrease the incidence of bronchospasm. Atropine sulfate is administered to dry oral and

nasal secretions. Although cimetidine is useful for gastric ulcer therapy, gastric ulcers are not a common effect associated with operative births.

 CN: Pharmacological and parenteral therapies; CL: Apply

The Labor Experience

56. 1. If presenting part is above the ischial spines 1 cm, the station is -1 . If the presenting part is 1 cm below the ischial spines, the station is $+1$. Engaged and floating are not descriptive of station.

 CN: Reduction of risk potential; CL: Apply

57. 1. Closed glottis pushing, or when a woman is told to hold her breath when she pushes typically while the nurse typically counts to 10, creates the Valsalva maneuver and is associated with decreased perfusion. Open glottis pushing, on the other hand, encourages women to listen to their own body cues for when to breathe and when to bear down. “Rest and descent” and squatting have positive influences on second stage of labor and birth.

 CN: Reduction of risk potential; CL: Analyze

58. 3. Placing the client in the hands and knees position pulls the fetal head away from the sacral promontory (relieving pain) and facilitates rotation of the fetus to the anterior position. Lithotomy is the position preferred by some **healthcare providers (HCP)** for birth but does not facilitate rotation. The right lateral position will perpetuate the ROP position. Tailor sitting facilitates descent in OA positions.

 CN: Basic care and comfort; CL: Apply

59. 3. A trial labor in this context means that the woman is allowed to go into labor, and her progress is assessed by cervical dilation and effacement as well as fetal descent evaluated to determine whether to allow the labor to progress to birth. If there are indications that labor is not progressing, other means of birth are considered. Labor stimulation is used cautiously and may not be safe. The presence of contractions every 5 minutes indicates true labor. If fetal distress is noted and an emergency cesarean section cannot be done immediately, tocolytic agents may be considered to stop contractions.

 CN: Management of care; CL: Analyze

60. 2. Lumbar epidural anesthesia is usually administered with the client in a sitting or a left side-lying position with shoulders parallel and legs slightly flexed. These positions expose the vertebrae to the anesthesiologist. Paracervical and local anesthetics are usually administered with the client in the lithotomy position. The hands and knees and prone positions are not used for anesthesia administration.

CN: Pharmacological and parenteral therapies; CL: Apply

61. 2. The nurse should turn the client to the side to reduce pressure on the abdominal aorta. The IV fluid rate would be increased, not decreased. There is no information indicating the client has a full bladder or requires a vaginal examination.

CN: Management of care; CL Synthesize

62. 2. The nurse would document these findings as “early” decelerations. Early decelerations are thought to be the result of vagal nerve stimulation caused by compression of the fetal head during labor. They are considered normal physiologic response to labor and do not require any intervention. Early decelerations do not require position change or O2 as they are not a sign of fetal distress. Variable decelerations are thought to be due to umbilical cord compression. Early decelerations are not emergent and do not require immediate reporting to the **healthcare provider (HCP)**  or preparing for caesarean section.

CN: Management of care CL; Synthesize

63. 4. Transition is the most difficult period of the labor process, and often when clients are tired, pain becomes more intensified. Clients during this stage verbalize anger and are outspoken and difficult to comfort. The most logical next step would be to determine if the client has completed transition and is ready to begin pushing. Performing a vaginal exam would provide this answer. The use of narcotic medications is discouraged at this stage as they can lead to respiratory depression in the neonate. Palpating the bladder is an important intervention but not the highest priority as it was done less than an hour ago. Since the nurse has correctly completed the most logical steps, asking for the client’s input would certainly be in order but not the highest priority intervention.

 CN: Basic care and comfort; CL: Apply

64. 3. The expected outcome of magnesium sulfate administration is suppression of the contractions because the client is in preterm labor. Magnesium sulfate is a smooth muscle relaxant used to slow and stop contractions and is one of the most common tocolytic agents in the United States. Having contractions that lead to birth is not the intended effect of this drug when used for preterm labor. Respirations lower than 12 breaths/min may indicate magnesium sulfate toxicity. Another use of magnesium sulfate is to treat preeclampsia by preventing seizures and, secondarily, lowering maternal blood pressure. However, in this scenario, preterm labor—not preeclampsia—is being treated.

 CN: Pharmacological and parenteral therapies; CL: Evaluate

65. 4. Betamethasone is a corticosteroid that induces the production of surfactant. The pulmonary maturation that results causes the fetal lungs to mature more rapidly than normal. Because the lungs are mature, the risk of respiratory distress in the neonate is lowered but not eliminated. Betamethasone also decreases the surface tension within the alveoli. Betamethasone has no influence on contractions or carrying the fetus to full term. It also does not prevent infection.

 CN: Pharmacological and parenteral therapies; CL: Evaluate

66. 1. A Bishop score evaluates cervical readiness for labor based on five factors: cervical softness, cervical effacement, dilation, fetal position, and station. A Bishop score of 5 or greater in a multipara or a score of 8 or greater in a primipara indicate that a vaginal birth is likely to result from the induction process. The nurse should expect that labor will be induced using oxytocin because the Bishop score indicates that the client is 60% to 70% effaced, 3 to 4 cm dilated, and in an anterior position. The cervix is soft and the presenting part is at a –1 to 0 position. Prostaglandin gel, misoprostol, and dinoprostone are all cervical ripening agents, and the doses are accurate; however, cervical ripening has already taken place.

 CN: Pharmacological and parenteral therapies; CL: Synthesize

67. 3. Cervical ripening, or creating a cervix that is soft, anterior, and

dilated to 2 to 3 cm, must occur before the cervix can efface and dilate with oxytocin. Drugs to accomplish this goal include dinoprostone, misoprostol, and prostaglandin E2. Nalbuphine is a narcotic analgesic used in early labor and has no influence on the cervix. Betamethasone is a corticosteroid given to mature fetal lungs.

CN: Pharmacological and parenteral therapies; CL: Apply

68. 2. Typically, a client will be able to have an epidural when she is 3 to 4 cm dilated or the active phase of labor has been established. Waiting until the cervix is dilated to this point ensures that the client is in labor and the epidural is less likely to halt labor contractions. Nalbuphine and promethazine are used to provide relief until the client is about 7 cm dilated. If given after this time, narcotics may cause neonatal respiratory depression in the neonate. The majority of clients have an epidural or spinal for a cesarean section. The only time general anesthesia is used is for an emergency cesarean section.

CN: Pharmacological and parenteral therapies; CL: Evaluate

69. 1,2,3,5. The time of rupture; color, odor, amount, and clarity of amniotic fluid; and FHR and pattern before and after the procedure are all information that must be documented on the client's record. There is only one size for an amnio hook.

CN: Management of care; CL: Create

70. 2. The client is experiencing uterine hyperstimulation from the oxytocin. The first intervention should be to stop the oxytocin infusion, which may be the cause of the long, frequent contractions, elevated resting tone, and abnormal fetal heart patterns. Only after turning off the oxytocin should the nurse turn the client to her left side to better perfuse the mother and fetus. Then, she should increase the maintenance IV fluids to allow available oxygen to be carried to the mother and fetus. When all other interventions are initiated, she should notify the **HCP**.

CN: Management of care; CL: Synthesize

71. 4. Late decelerations on a fetal heart monitor indicate uteroplacental insufficiency. Interventions to improve perfusion include repositioning the

client, oxygen, and IV fluids. A sterile vaginal exam is not indicated at this time. Late decelerations are not expected findings and do not indicate an imminent birth.

CN: Management of Care; CL: Analyze

72. 4. Accelerations that are episodic and occur during fetal movement demonstrate fetal well-being. Turning the client to the left side, applying oxygen by face mask, and notifying the **HCP** are interventions used for late and variable decelerations indicating the fetus is not tolerating the induction process well.

CN: Physiological adaptation; CL: Synthesize

73. 1. The client with preeclampsia would be a candidate for the induction process because ending the pregnancy is the only way to cure preeclampsia. A client with active herpes would be a candidate for a cesarean section to prevent the fetus from contracting the virus while passing through the birth canal. The woman with a face presentation will not be able to give birth vaginally due to the extended position of the neck. The client whose fetus exhibits late decelerations without oxytocin would be at greater risk for fetal distress with use of this drug. Late decelerations indicate the fetus does not have enough placental reserves to remain oxygenated during the entire contraction. This client may require a cesarean section.

CN: Management of care; CL: Evaluate

74. 2. Removing a fetal monitor from a client and assisting her to the bathroom are within the realm of practice of a **UAP**.  Performing a fundal check is an assessment, which is a responsibility of an **RN**.  A UAP is not permitted to administer medication by any route. Education is also part of the professional nursing role. Although a UAP can assist a mother with bottle-feeding, the formal client education must be completed and validated by the nurse.

CN: Management of care; CL: Evaluate

75. 3. When the fetal head is compressed, early decelerations are seen as a vagal response occurs and the fetal heart rate decelerates and inversely mirrors the contraction. This response commonly occurs when the client is 9

to 10 cm dilated or pushing. If communication cannot be facilitated, early decelerations are one indicator that birth may be approaching. Late decelerations may occur at this time but indicate uteroplacental insufficiency rather than imminent birth. At any time during the labor process, the client may communicate with her family in her native language. The client's facial expressions may change at any point during labor and cannot be used as an indicator of imminent birth.

CN: Physiological adaptation; CL: Analyze

The Intrapartal Client with Risk Factors

76. 1,2,3. With abruptio placentae, bleeding may occur vaginally, may be obstructed by the fetal head, or it may be hidden behind a portion of the placenta. Abdominal rigidity occurs, particularly with a concealed hemorrhage because the girth and fundal height increase. Abdominal pain is one of the classic symptoms of abruption. The pain may be intermittent, as in labor contractions, or continuous. The placenta with abruption is not larger than a normal placenta, and the bleeding does not end spontaneously.

CN: Physiological adaptation; CL: Analyze

77. 3. The multigravid client with class II heart disease has a slight limitation of physical activity and may become fatigued with ordinary physical activity. A side-lying or semi-Fowler's position with the head elevated helps to ensure cardiac emptying and adequate oxygenation. In addition, oxygen by mask, analgesics and sedatives, diuretics, prophylactic antibiotics, and digitalis may be warranted. Although breathing slowly during a contraction may assist with oxygenation, it would have no effect on cardiac emptying. It is essential that the laboring woman with cardiac disease be relieved of discomfort and anxiety. Effective intrapartum pain relief with analgesia and epidural anesthesia may reduce cardiac workload as much as 20%. Local anesthetics are effective only during the second stage of labor.

CN: Reduction of risk potential; CL: Synthesize

78. 4. Assessing for signs and symptoms associated with cardiac decompensation is the priority. Class III heart disease during pregnancy has a 25% to 50% mortality. These clients are markedly compromised, with

marked limitation of physical activity. They frequently experience fatigue, palpitations, dyspnea, or anginal pain. A pulse rate >100 bpm or a respiratory rate >25 breaths/min may indicate cardiac decompensation that could result in cardiac arrest. Additional symptoms include dyspnea, peripheral edema, orthopnea, tachypnea, rales, and hemoptysis.

CN: Reduction of risk potential; CL: Analyze

79. 1. Before administering prostaglandin E2 gel, the nurse would assess the frequency and duration of any uterine contractions first because prostaglandin E2 gel is contraindicated if the client is having contractions. If there are no contractions, the client should be placed in a semi-Fowler's position to allow for vaginal insertion of the gel. Although determining whether the client's membranes have ruptured is part of the assessment of any client in labor, it is not specifically related to the administration of prostaglandin E2 gel. If the membranes remain intact, an amniotomy may be performed once the client begins to dilate and the fetal head is engaged. However, it is not necessary for the nurse to prepare the client for this procedure at this time.

CN: Pharmacological and parenteral therapies; CL: Synthesize

80. 4. A prolonged second stage of labor with a large fetus could indicate a shoulder dystocia at birth. Immediate nursing actions for a shoulder dystocia include suprapubic pressure and the McRoberts maneuver. If after interventions for vaginal birth with a shoulder dystocia fail, an emergency cesarean birth may be needed but is not indicated at this time. A vacuum-assisted birth would be contraindicated due to increased risk of shoulder dystocia with a macrosomic infant. An IV fluid bolus may be indicated for fetal distress, but there is not enough information to establish that they are needed at this time.

CN: Physiologic adaptation; CL: Apply

81. 4. Assessing the fetal heart rate is always a priority after spontaneous rupture of membranes has occurred. Also a common sign of fetal distress related to an inadequate transfer of oxygen to the fetus is meconium-stained fluid. Because the fetus has suffered hypoxia, close fetal heart rate monitoring is necessary. In addition, all clients are monitored continuously

after rupture of membranes for fetal distress caused by cord prolapse. If there are increasing signs of fetal distress (e.g., late decelerations), the **healthcare provider (HCP)** should be notified immediately. A cesarean birth may be performed for fetal distress. Increasing the rate of the oxytocin infusion could lead to further fetal distress. Turning the client to the left side, rather than a knee-chest position, improves placental perfusion. The HCP may wish to determine the extent of cervical dilation to make a decision about whether a cesarean birth is warranted, but continuous fetal heart rate monitoring is essential to determine fetal status.

CN: Reduction of risk potential; CL: Synthesize

82. 3. Neonates born to mothers who smoke tend to have lower-than-average birth weights. Neonates born to mothers who smoke also are at higher risk for stillbirth, sudden infant death syndrome, bronchitis, allergies, delayed growth and development, and polycythemia. Maternal smoking is not related to higher neonatal sedation, hyperbilirubinemia, or hypocalcemia. Smoking may cause irritability, not sedation. Hyperbilirubinemia is associated with Rh or ABO incompatibility or the administration of intravenous oxytocin during labor. Approximately 50% of neonates born to mothers with insulin-dependent diabetes experience hypocalcemia during the first 3 days of life.

CN: Health promotion and maintenance; CL: Analyze

83. 3. The client should be urged to push with an open glottis to prevent the Valsalva maneuver. Pushing with a closed glottis increases intrathoracic pressure, preventing venous return. Blood pressure also falls, and cardiac output decreases. Pushing for at least 1 to 3 minutes is too long; prolonged pushing can lead to reduced blood flow and fatigue. Pushing for the duration of the contraction is sufficient. Pushing while holding the breath results in the Valsalva maneuver. Because the client has had an epidural anesthetic, she may not feel the urge to push and may need coaching during the pushing phase.

CN: Pharmacological and parenteral therapies; CL: Create

84. 3. When the fetal skull is on the perineum with the scalp visible at the perineal floor or vaginal opening, this is considered outlet forceps

application. When the head is higher in the pelvis but engaged and its greatest diameter has passed the inlet, the operation is termed midforceps. Midforceps births are not recommended because they are extremely dangerous for the mother and fetus because of the possibility of uterine rupture. If the head is not engaged, at -1 station, this is termed high forceps. High-forceps births also are exceedingly dangerous for both the mother and fetus because of the possibility of uterine rupture and are not recommended. Cesarean birth is preferred in these situations. The fetal head at station +2 or lower is termed low forceps.

CN: Reduction of risk potential; CL: Apply

85. 1. Oligohydramnios, or a decrease in the volume of amniotic fluid, is associated with variable fetal heart rate decelerations due to cord compression. Maintenance of an adequate amniotic fluid volume during labor provides protective cushioning of the umbilical cord and minimizes cord compression. Cord compression can result in fetal metabolic acidosis, not alkalosis. Amnioinfusion is used to minimize cord compression, not to increase the fetal heart rate accelerations during a contraction. The goal is to maintain the amniotic fluid index at 8 cm. This can be determined by ultrasound.

CN: Reduction of risk potential; CL: Apply

86. 4. A primigravid client diagnosed with preeclampsia has the potential for developing seizures (eclampsia). This client should be in a room with the least amount of stimulation possible to reduce the risk of seizures and as close to the nurses' station as possible in case the client requires immediate assistance. Bright lighting and sunshine can be a stimulant, possibly increasing the risk of seizures, as can being in a semiprivate room with roommate, visitors, conversation, and noise.

CN: Management of care; CL: Synthesize

87. 4. The client is experiencing a precipitous birth. The nurse should remain calm during a precipitous birth. Explaining to the client what is happening as the birth progresses and how she can assist is likely to help her remain calm and cooperative. Maintaining eye contact is also beneficial. Telling the client that she is right and to just relax is inappropriate because

the client may not be able to relax because of the strong urge to push the fetus out of the birth canal. Telling the client not to push because she may tear the cervix can instill fear, not cooperation. Saying that the **healthcare provider (HCP)** 📖 will be there soon may not be an accurate statement and is not reassuring if the client is concerned about the birth.

🔑 CN: Psychosocial integrity; CL: Apply

88. 2. During a precipitous birth, after calling for assistance and helping the client lie down, the nurse should provide support to the fetal head to prevent too rapid of emergence leading to injury. It is not appropriate to tell the client to push between contractions because this may lead to lacerations. The shoulder should be delivered by applying downward traction until the anterior shoulder appears fully at the introitus, then upward pressure to lift out the other shoulder. Priority should be given to safe birth of the infant over protecting the perineum by massage.

🔑 CN: Reduction of risk potential; CL: Synthesize

89. 2. Because birth occurs so rapidly and the fetus is propelled quickly through the birth canal, the major complication of a precipitous birth is a boggy fundus, or uterine atony. The neonate should be put to the breast, if the mother permits, to allow for the release of natural oxytocin. In a hospital setting, the **healthcare provider (HCP)** 📖 will probably prescribe administration of oxytocin. The nurse should gently massage the fundus to ensure that it is firm. There is no relationship between a precipitous birth and postpartum “blues” or intrauterine infection. Postpartum “blues” usually do not occur until about 3 days postpartum, and symptoms of postpartum infection usually occur after the first 24 hours. There is no relationship between a precipitous birth and urinary tract infection even though the birth has been accomplished under clean rather than sterile technique. Symptoms of urinary tract infection typically begin on the first or second postpartum day.

🔑 CN: Reduction of risk potential; CL: Analyze

90. 2. A sinusoidal pattern is an ominous sign that reflects an absence of autonomic nervous control over the fetal heart rate resulting from severe hypoxia. Sinusoidal patterns, while rare, are associated with Rh sensitization,

fetal hydrops, and anemia. This client will most likely require a cesarean birth to improve the fetal outcome. Variable decelerations, associated with cord compression, and late decelerations, associated with poor placental perfusion, are concerning but may correct with appropriate interventions. Early decelerations are associated with head compression and are considered a normal variation.

CN: Reduction of risk potential; CL: Analyze

91. 1. A priority assessment for the nurse to make is to determine the estimated date of birth or probable gestational age of the fetus. If the gestation is <37 weeks, the neonatal team should be called to begin resuscitative efforts if needed. Amniotic fluid status is not important at this point, because if the fetal skull is crowning, birth is imminent. Determination of gravida and parity is part of the normal nursing history, but the priority is the status of the fetus and safe birth. Prenatal history is part of the nursing assessment, but this information is not especially relevant until the fetus is safely born and has been given immediate care.

CN: Health promotion and maintenance; CL: Analyze

92. 2. It is important that the parents be allowed to touch, hold, and participate in care of the twins whenever they desire. Ideally, this will be on a daily basis, to promote parent-infant bonding. It is not appropriate to discuss how the couple will cope with twin infants at home until they are ready to take the infants home. They are too overwhelmed at this point and are focused on the well-being of their infants while hospitalized. Having the couple visit the twins to provide care on a 24-hour basis is not warranted. Identifying complications that may occur is not appropriate. If complications arise, the parents should be well informed and given opportunities for discussion related to the care provided.

CN: Psychosocial integrity; CL: Create

93. 4. Birth trauma and prolonged ruptured membranes make risk for infection the priority problem for this client. Infection can be a serious postpartum complication. Although the client may be fatigued, she should not be experiencing activity intolerance. Clients with heart disease may - experience activity intolerance due to excessive cardiac workload. Although

the client may be experiencing sleep deprivation, most clients are alert and awake after birth of a neonate. Situational low self-esteem is not a priority. Clients who undergo a cesarean birth commonly feel a sense of failure because of not having a vaginal birth experience, but this is not the case for this client.

CN: Reduction of risk potential; CL: Analyze

94. 2. Postmature neonates commonly have difficulty maintaining adequate glucose reserves and usually develop hypoglycemia soon after birth. Other common problems include meconium aspiration syndrome, polycythemia, congenital anomalies, seizure activity, and cold stress. These complications result primarily from a combination of advanced gestational age, placental insufficiency, and continued exposure to amniotic fluid. Delayed meconium is not associated with postterm gestation. Hyperbilirubinemia occurs in term neonates as well as postterm neonates, but unless there is an Rh incompatibility, it does not develop until after the first 24 hours of life.

CN: Reduction of risk potential; CL: Analyze

95. 4. Polyhydramnios is an abnormally large amount of amniotic fluid in the uterus. The client has understood the instructions when the client states that polyhydramnios is associated with gastrointestinal disorders (e.g., tracheoesophageal fistula). Polyhydramnios is also associated with maternal illnesses such as diabetes and anemia. Other fetal/neonatal disorders associated with this condition include congenital anomalies of the central nervous system (e.g., anencephaly), upper gastrointestinal obstruction, and macrosomia. Polyhydramnios can lead to preterm labor, premature rupture of the membranes, and cord prolapse. Renal dysfunction and intrauterine growth restriction are associated with oligohydramnios, not polyhydramnios. Pulmonary hypoplasia (poorly developed lungs) is associated with prolonged oligohydramnios.

CN: Reduction of risk potential; CL: Evaluate

96. 1. If a client has been in active labor and there is no change in cervical dilation after 2 hours, the nurse should suspect cephalopelvic disproportion. This may be caused by an inadequate pelvis size of the mother or by a large-

for-gestational-age fetus. The **healthcare provider (HCP)**  should be notified about the client's lack of progress. If the fetus cannot descend, a cesarean birth is warranted. The client is not experiencing a prolonged latent phase (0- to 3-cm dilation) because her cervix is dilated to 6 cm. She has not reached the transitional phase, characterized by a cervical dilation of 8 to 10 cm. With a hypotonic labor pattern, contractions are painful but far apart and not very intense. This client's contractions are of moderate intensity.

 CN: Reduction of risk potential; CL: Analyze

97. 3. Preparation for cesarean birth is similar to preparation for any abdominal surgery. The client must give **informed consent**.  Another person may not sign for the client unless the client is unable to sign the form. If this is the case, only certain designated people can do so legally. The husband does not need to sign the form unless his wife is unable to do so. In a life threatening emergency, surgery may be performed without a written consent. The HCP does not need to witness the consent.

 CN: Management of care; CL: Synthesize

98. 4. Decreased variability may be seen in various conditions. However, it is most commonly caused by analgesic administration. Other factors that can cause decreased variability include anesthesia, deep fetal sleep, anencephaly, prematurity, hypoxia, tachycardia, brain damage, and arrhythmias. Maternal fatigue, fetal malposition, and small-for-gestational-age fetus are not commonly associated with decreased variability.

 CN: Health promotion and maintenance; CL: Apply

99. 4. Respiratory distress syndrome is more common in neonates born by cesarean section than in those born vaginally. During a vaginal birth, pressure is exerted on the fetal chest, which aids in the fetal inhalation and exhalation of air and lung expansion. This pressure is not exerted on the fetus with a cesarean birth. Congenital anomalies are not more common with cesarean birth. Pulmonary hypertension occurs more commonly in infants with meconium aspiration syndrome, congenital diaphragmatic hernia, respiratory distress syndrome, or neonatal sepsis, not with cesarean birth. Meconium aspiration syndrome occurs more commonly with vaginal birth, postterm neonate, and prolonged labor, not with cesarean birth.

CN: Health promotion and maintenance; CL: Apply

100. 4. Congenital anomalies are not related to maternal urinary tract infections. A multigravid client with acute pyelonephritis is susceptible to preterm labor, premature rupture of the membranes, maternal sepsis, intrauterine growth restriction, and fetal loss. The most common organism responsible for the urinary tract infection is *Escherichia coli*.

CN: Reduction of risk potential; CL: Evaluate

101. 1. Conjunctivitis is a common complication of neonates who are born to mothers with untreated chlamydial infection. Neonatal pneumonia is another condition associated with chlamydial infection of the mother. Untreated chlamydial infection is not associated with heart disease or brain damage. Exposure to rubella may lead to neonatal heart defects, and brain damage may occur as a result of prolonged shoulder dystocia or difficulty delivering the fetal head during a vaginal breech birth. Occasionally, because of immature circulation, a neonate who has been lying on his or her side appears red on one side of the body. This “harlequin sign” is transient and is of no clinical significance. Presence of a harlequin sign is unrelated to untreated chlamydial infection.

CN: Reduction of risk potential; CL: Apply

102. 1. The purpose of the RhoGAM is to provide passive antibody immunity and prevent Rh-positive sensitization with the next pregnancy. It should be given within 72 hours after birth of an Rh-positive neonate. Clients who are Rh negative and conceive an Rh-negative fetus do not need antibody protection. Rh-positive cells contribute to sensitization, not Rh-negative cells. The RhoGAM does not cross the placenta and destroy fetal Rh-positive cells.

CN: Reduction of risk potential; CL: Apply

103. 3. Because magnesium sulfate is a central nervous system depressant, the nurse should plan to assess the client’s respiratory rate every hour. If the respiratory rate is <12 breaths/min, the client may be experiencing magnesium sulfate overdose. Urinary output via an indwelling catheter should be assessed hourly and should be at least 30 mL/h. Deep tendon reflexes and blood pressure should also be assessed every hour. At some

institutions, continuous electronic blood pressure monitoring will be performed.

CN: Pharmacological and parenteral therapies; CL: Analyze

104. 2. For a client diagnosed with probable placenta previa, hypovolemic shock is a complication. Continuous blood pressure monitoring with an electronic cuff is the priority assessment after the client's admission. Once the client is admitted, an ultrasound examination will be performed to determine the placement of the placenta. Whole blood replacement is not warranted at this time. However, it may be necessary if the client demonstrates signs and symptoms of hemorrhage or shock. Internal fetal heart rate monitoring is contraindicated because the monitoring device may puncture the placenta and place both the mother and fetus in jeopardy. An immediate cesarean birth is not necessary until there has been an assessment of the amount of bleeding and the location of the placenta previa.

CN: Reduction of risk potential; CL: Apply

105. 4. Dramatic vasoconstriction occurs as a result of sniffing crack cocaine. This can lead to increased respiratory and cardiac rates and hypertension. It can severely compromise placental circulation, resulting in abruptio placentae and preterm labor and birth. Infants of these women can experience intracranial hemorrhage and withdrawal symptoms of tremulousness, irritability, and rigidity. Placenta previa, ruptured uterus, and maternal hypotension are not associated with cocaine use. Placenta previa may be associated with grand multiparity. Ruptured uterus may be associated with a large-for-gestational-age fetus.

CN: Reduction of risk potential; CL: Analyze

106. 2. Pregnant women who become infected with the rubella virus early in pregnancy risk having a neonate born with rubella syndrome. The symptoms include thrombocytopenia, cataracts, cardiac disorders, deafness, microcephaly, and motor and cognitive impairment. The most extensive neonatal effects occur when the mother is exposed during the first 2 to 6 weeks and up to 12 weeks' gestation, when critical organs are forming. Bulging fontanelles are associated with increased intracranial pressure and bacterial meningitis. Rubella is not associated with renal defects.

 CN: Reduction of risk potential; CL: Analyze

107. 3. To stop the process of DIC, the underlying insult that began the phenomenon must be halted. Treatment includes fresh frozen platelets or blood administration. The **HCP**  also may prescribe heparin before the administration of blood products to restore the normal clotting mechanism. Immediate birth of the fetus is essential. Magnesium sulfate is given for pregnancy-induced hypertension or preterm labor. Heparin, not warfarin sodium, is used to treat DIC. Meperidine hydrochloride is used for pain relief.

 CN: Pharmacological and parenteral therapies; CL: Apply

108. 2. Magnesium sulfate may be used as an anticonvulsive or a tocolytic agent. The intended effect for this client is to decrease the number and frequency of contractions. Even though this client has chronic hypertension, the first goal is to prevent birth in a 34 weeks' gestation client. If the blood pressure moves into the therapeutic range, that is a benefit for the client, but it is not the major goal. Magnesium sulfate may decrease the accelerations found in this fetus as it decreases the ability of the infant to respond, acting on the infant in the same way it does on the mother. Maternal respiratory rate may also decrease, and a lower respiratory rate to 12 respirations/min indicates that this level of magnesium sulfate is becoming toxic to this client.

 CN: Pharmacological and parenteral therapies; CL: Evaluate

109. 1. Although thioamides such as propylthiouracil and methimazole are considered teratogenic to the fetus and can lead to congenital hyperthyroidism (goiter) in the neonate, they still represent the treatment of choice. The client should be regulated on the lowest possible dose. Hyperthyroidism is associated with preterm labor and a low-birth-weight infant, so the client should contact the **HCP**  if the contractions begin again. The client should not be urged to breast-feed, because medications such as propylthiouracil and methimazole are secreted in breast milk. Tachycardia (not bradycardia) is associated with thyroid storm, a medical emergency, and should be reported to the HCP.

 CN: Pharmacological and parenteral therapies; CL: Apply

110. 4. The first action by the nurse should be to call for immediate

assistance in the client's room because this is an emergency. Throughout the seizure, the nurse should note the time and length of the seizure and continue to monitor the status of both client and fetus. The side rails should have been padded at the time of the client's admission to the hospital as part of seizure precautions. The client should be turned to her left side to improve placental perfusion. Inserting a tongue blade is not recommended because it can further obstruct the airway or cause injury to the client's teeth.

CN: Safety and infection control; CL: Synthesize

111. 3. In an abusive situation, the client's safety is the priority. The nurse should refer the client to a social worker who can provide the client with options such as a safe shelter. Commonly clients who are battered feel powerless and fear that the batterer will kill them. As a result, they remain in the abusive situation. Telling the client to leave the boyfriend immediately is not helpful and reflects the values of the nurse. Although asking about fetal movement is important and is part of a routine assessment, a sonogram can be performed to confirm fetal well-being. The referral is more important at this time. Although it may be part of the unit's policies and procedures to report any incidents such as this one to the unit supervisor, the client's immediate need for safety must be addressed first.

CN: Management of care; CL: Apply

112. 1. The client's symptoms are indicative of amniotic fluid embolism, which is a medical emergency. After calling for assistance, the first action should be to administer oxygen by face mask or cannula to ensure adequate oxygenation of mother and fetus. If the client needs cardiopulmonary resuscitation, this can be started once oxygen has been administered. If the client survives, disseminated intravascular coagulation will probably develop, and the client will need intravenous fibrinogen and heparin. Oxytocin, a vasoconstrictor, is not warranted for amniotic fluid embolism.

CN: Physiological adaptation; CL: Synthesize

Managing Care, Quality, and Safety for Clients Giving Birth

113. 2. The nurse will need to assess the client's ability to bear weight

before taking her to the bathroom. If she cannot bear weight, she will be unable to ambulate. Asking the client to remain in bed until the assessments are complete sets the client up for increased postpartum bleeding, as the bladder will displace the uterus. Encouraging the client to sit at the bedside is an excellent strategy to prevent orthostatic hypotension, but it will not give the nurse an idea if the client can ambulate. Having a staff member with the client is also correct for the first ambulation of this client, but the ability to bear weight and walk will need to be assessed first.

CN: Reduction of risk potential; CL: Synthesize

114. 1,4,5. In most settings, the charge nurse coordinates and directs the activities of the unit. Prior to the change of shift, the nurse will review and update the status of each of the laboring clients on the unit to include any difficulties or unusual situations that may be occurring with each of them, including following up with a primary nurse after a birth. A change-of-shift report with the oncoming charge nurse is among the last activities completed before ending the shift. Activities such as admitting a client in labor and completing the nursing responsibilities of the nurse who had to leave 30 minutes early can be delegated to staff members. In an emergency, the charge nurse could assume responsibility for client care.

CN: Management of care; CL: Create

115. 4. The client at 42 weeks' is the greatest concern, and the nurse should make rounds on this client first based on the length of the pregnancy and the green color of the amniotic fluid. Bloody show is a normal sign of impending labor as the cervix may be beginning to dilate. Not having contractions after rupture of membranes is not unusual within a 1-hour time frame. The green amniotic fluid indicates that fetal distress has recently occurred to the point that the fetus had a bowel movement in utero. Along with the 42-week gestation, this fetus is at greatest risk. The nurse can see the primipara in active labor at 5-cm dilation last; this client is in pain, but nothing about her situation indicates anything, but a normal labor process and as a primipara, her labor process will be slow. The client who is completely effaced, 8 cm dilated, and at +2 station as a primipara usually moves through labor at a slower pace than does a multiparous client. She is experiencing nausea that is an expected situation as a laboring client enters transition. The

client with no prenatal care is a cause for concern as the nurse knows nothing about her background. Her blood pressure is elevated, an indicator of mild preeclampsia, but there is no other indications of worsening preeclampsia, such as headache, visual disturbances, or epigastric pain.

CN: Management of care; CL: Synthesize

116. 1,2,3,4. Assuring the safety of this client is the top priority. The nurse should begin either intermittent or continuous fetal and contraction monitor depending on the client's risk status. Since the client is 8 cm dilated and a multigravid client, asking other staff members to set up the birthing table would be in order. This client is not a candidate for medication as this may have an influence on the baby. This client is past the point of offering an epidural as she may have given birth by the time the medication is in effect, but comfort measures such as warm or cool cloths, back rubs, etc., may be helpful. The support system is an important aspect of the birthing process and is an easily settled situation. Preparing to give an early report to the oncoming nurse does not apply in this situation.

CN: Management of care; CL: Create

117. 3. In emergency situations, verbal prescriptions should be entered into the **medical record**  or chart and signed immediately after the emergency. The nurse taking this prescription and giving the medication needs to call the **HCP**,  explain the prescription and that the medication was administered per the verbal prescription, and request that the HCP write the correct prescription. If the nurse misunderstood the prescription and gave the medication by the wrong route, an incident report will need to be initiated. The charge nurse would become involved if an error has occurred, an incident report is needed, or there is difficulty between the nurse and HCP that cannot be remediated. Rectifying this prescription is the responsibility of the implementing nurse. Waiting until the HCP comes back to the hospital unit may not occur quickly enough to safely care for the client.

CN: Management of care; CL: Synthesize

118. 1,2,4,5. The Code of Ethics describes those actions by the nurse that guide their practice. It is the responsibility of each nurse to be active in determining policy for health care for all citizens and assuring that the way

nursing is practiced is of the highest caliber. Nursing needs to participate in the development of health care of the future, while caring for all members of society. In order to be productive in shaping policy, nurses need to be politically astute while growing personally and professionally to meet the needs of clients. The Code of Ethics does not address compensation for work.

 CN: Management of care; CL: Apply

119. 2,3. Intact membranes act as a barrier to prevent infections. Once a client's membranes have ruptured, it is important to take precautions to limit introducing bacteria into the genital tract. Using sterile gloves and sterile lubricant for cervical checks help reduce the risk of infection. A sterile speculum is only needed to diagnose if the membranes have ruptured. An amnio hook would only be indicated if the plan was to artificially rupture the membranes. Cervical dilators are not used for cervical checks in labor.

 CN: Management of care; CL: Apply

120. 2. The best candidate for a VBAC is a woman who had a cesarean section in her last birth because of a problem related to the infant that is not repeated in this pregnancy. The woman with the breech presentation in her last birth and a vertex pregnancy in this pregnancy would be the best candidate, especially if she had other vaginal births. The woman who was unable to dilate beyond 6 cm (failure to progress) may try a VBAC but is likely to experience the same problem with this birth. The woman with the very large infant is likely to experience cephalopelvic disproportion with this birth if she experienced cephalopelvic disproportion with her last infant who was large. A classic cesarean section scar is a contraindication for a VBAC because that type of scar may not be strong enough to withstand the stress of hours of uterine contractions and may result in a uterine disruption.

Postpartal Care

- The Postpartal Client with a Vaginal Birth
- The Postpartal Client Who Breast-feeds
- The Postpartal Client Who Bottle-feeds
- The Postpartal Client with a Cesarean Birth
- The Postpartal Client with Complications
- Managing Care, Quality, and Safety of Postpartal Clients
- Answers, Rationales, and Test-Taking Strategies

The Postpartal Client with a Vaginal Birth

1. The nurse from the nursery is bringing a newborn to a mother's room. The nurse took care of the mother yesterday and knows the mother and baby well. The nurse should implement which action next to ensure the safest transition of the infant to the mother?

- ☐ **1.** Assess whether the mother is able to ambulate to care for the infant.
- ☐ **2.** Ask the mother if there is anything else she needs for the care of her baby.
- ☐ **3.** Check the crib to determine if there are enough diapers and formula.
- ☐ **4.** Complete the hospital identification procedure with mother and infant.

2. A client is in the first hour of her recovery after a vaginal birth. During an assessment, the lochia is moderate, is bright red, and is trickling from the vagina. The nurse locates the fundus at the umbilicus; it is firm and midline with no palpable bladder. The client's vital signs remain at their baseline. Based on this information, the nurse would implement which action?

- ☐ **1.** Increase the IV rate.
- ☐ **2.** Recheck the admission hematocrit and hemoglobin levels.

- ☐ 3. Report the findings to the healthcare provider (HCP).
- ☐ 4. Document the findings as normal.

3. The nurse is caring for a multigravida woman who is 1 day postpartum following a vaginal birth. Which finding indicates a need for further assessment?

- ☐ 1. hemoglobin 12.1 g/dL (121 g/L)
- ☐ 2. WBC count of 15,000 ($15 \times 10^9/L$)
- ☐ 3. pulse of 60 beats/min
- ☐ 4. temperature of 100.8°F (38.2°C)

4. The nurse is providing follow-up care with clients 10 days after the birth of their neonate. The nurse would anticipate what outcomes from the new mother? Select all that apply.

- ☐ 1. The client feels tired but is able to care for herself and her new infant.
- ☐ 2. The family has adequate support from one another and others.
- ☐ 3. Lochia is changing from red to pink and is smaller in amount.
- ☐ 4. The client feeds the baby every 6 to 8 hours without difficulty.
- ☐ 5. The client has positive comments about her new infant.

5. A client gave birth vaginally 2 hours ago and has a third-degree laceration. There is ice in place on her perineum. However, her perineum is slightly edematous, and the client is having pain rated 6 on a scale of 1 to 10. Which nursing intervention would be the **most** appropriate at this time?

- ☐ 1. Begin sitz baths.
- ☐ 2. Administer pain medication per prescription.
- ☐ 3. Replace ice packs to the perineum.
- ☐ 4. Initiate prescription anesthetic sprays to the perineum.

6. A primigravid client gave birth vaginally 2 hours ago with no complications. As the nurse plans care for this postpartum client, which postpartum goal would have the **highest priority**?

- ☐ 1. By discharge, the family will bond with the neonate.
- ☐ 2. The nurse will demonstrate self-care and infant care by the end of the shift.
- ☐ 3. The nurse will state instructions for discharge during the first

postpartum day.

☐ 4. By the end of the shift, the nurse will describe a safe home environment.

7. In response to the nurse's question about how she is feeling, a postpartum client states that she is fine. She then begins talking to the baby, checking the diaper, and asking infant care questions. The nurse determines the client is in which postpartal phase of psychological adaptation?

- ☐ 1. taking in
- ☐ 2. taking on
- ☐ 3. taking hold
- ☐ 4. letting go

8. A client has admitted use of cocaine prior to beginning labor. After the infant is born, the nurse should anticipate the need to include which actions in the infant's plan of care?

- ☐ 1. urine toxicology screening
- ☐ 2. notifying hospital security
- ☐ 3. limiting contact with visitors
- ☐ 4. contacting local law enforcement

9. The nurse is evaluating the client who gave birth vaginally 2 hours ago and is experiencing postpartum pain rated 8 on scale of 1 to 10. The client is a multigravida breast-feeding mother who would like medication to decrease the pain in her uterus. Which of the medications listed on the prescriptions sheet would be the **most** appropriate for this client?

- ☐ 1. aspirin 1,000 mg PO every 4 to 6 hour PRN
- ☐ 2. ibuprofen 800 mg PO every 6 to 8 hour PRN
- ☐ 3. docusate 100 mg PO twice a day
- ☐ 4. acetaminophen and hydrocodone 10 mg 1 tab PO every 4 to 6 hour PRN

10. At which location would the nurse expect to palpate the fundus of a primiparous client immediately after birth of a neonate?

- ☐ 1. halfway between the umbilicus and the symphysis pubis
- ☐ 2. at the level of the umbilicus

- ☐ 3. just below the level of the umbilicus
- ☐ 4. above the level of the umbilicus

11. When instilling erythromycin ointment into the eyes of a neonate 1 hour old, the nurse would explain to the parents that the medication is used to prevent which problem?

- ☐ 1. chorioretinitis from cytomegalovirus
- ☐ 2. blindness secondary to gonorrhea
- ☐ 3. cataracts from beta-hemolytic streptococcus
- ☐ 4. strabismus resulting from neonatal maturation

12. The healthcare provider (HCP) prescribes an intramuscular injection of vitamin K for a term neonate. The nurse explains to the mother that this medication is used to prevent which problem?

- ☐ 1. hypoglycemia
- ☐ 2. hyperbilirubinemia
- ☐ 3. hemorrhage
- ☐ 4. polycythemia

13. The nurse assesses a swollen ecchymosed area to the right of an episiotomy on a primiparous client 6 hours after a vaginal birth. The nurse should **next**:

- ☐ 1. apply an ice pack to the perineal area.
- ☐ 2. assess the client's temperature.
- ☐ 3. have the client take a warm sitz bath.
- ☐ 4. contact the healthcare provider (HCP) for prescriptions for an antibiotic.

14. Two hours after the vaginal birth under epidural anesthesia, a client with a midline episiotomy ambulates to the bathroom to void. After voiding, the nurse assesses the client's bladder, finding it distended. The nurse interprets this finding based on the understanding that the client's bladder distention is **most** likely caused by which factor?

- ☐ 1. prolonged first stage of labor
- ☐ 2. urinary tract infection
- ☐ 3. pressure of the uterus on the bladder

- ☐ 4. edema in the lower urinary tract area

15. A primiparous client who is bottle-feeding her neonate at 12 hours after birth asks the nurse, “When will my menstrual cycle return?” Which response by the nurse would be **most** appropriate?

- ☐ 1. “Your menstrual cycle will return in 3 to 4 weeks.”
- ☐ 2. “It will probably be 6 to 10 weeks before it starts again.”
- ☐ 3. “You can expect your menses to start in 12 to 14 weeks.”
- ☐ 4. “Your menses will return in 16 to 18 weeks.”

16. While the nurse is preparing to assist the primiparous client to the bathroom to void 6 hours after a vaginal birth under epidural anesthesia, the client says that she feels dizzy when sitting up on the side of the bed. The nurse explains that this is **most** likely caused by which factor?

- ☐ 1. effects of the anesthetic during labor
- ☐ 2. hemorrhage during the birth process
- ☐ 3. effects of analgesics used during labor
- ☐ 4. decreased blood volume in the vascular system

17. The nurse enlists the aid of an interpreter when caring for a primiparous client from Mexico who speaks only Spanish and gave birth to a term neonate 8 hours ago. When developing the postpartum dietary plan of care for the client, the nurse would encourage the client’s intake of which foods?

- ☐ 1. tomatoes
- ☐ 2. potatoes
- ☐ 3. corn products
- ☐ 4. meat products

18. Three hours postpartum, a primiparous client’s fundus is firm and midline. On perineal inspection, the nurse observes a small, constant trickle of blood. Which condition should the nurse assess further?

- ☐ 1. retained placental tissue
- ☐ 2. uterine inversion
- ☐ 3. bladder distention
- ☐ 4. perineal lacerations

19. At a postpartum checkup 11 days after childbirth, the nurse asks the client about the color of her lochia. Which color is expected?

- ☐ 1. dark red
- ☐ 2. pink
- ☐ 3. brown
- ☐ 4. white

20. After instructing a primiparous client about episiotomy care, which client statement indicates successful teaching?

- ☐ 1. "I will use hot, sudsy water to clean the episiotomy area."
- ☐ 2. "I wipe the area from front to back using a blotting motion."
- ☐ 3. "Before bedtime, I will use a cold water sitz bath."
- ☐ 4. "I can use ice packs for 3 to 4 days after birth."

21. A primiparous client, 20 hours after childbirth, asks the nurse about starting postpartum exercises. Which instruction would be **most** appropriate to include in the plan of care?

- ☐ 1. Start in a sitting position, then lie back, and return to a sitting position, repeating this five times.
- ☐ 2. Assume a prone position, and then do push-ups by using the arms to lift the upper body.
- ☐ 3. Flex the knees while supine, and then inhale deeply and exhale while contracting the abdominal muscles.
- ☐ 4. Flex the knees while supine, and then bring chin to chest while exhaling and reach for the knees by lifting the head and shoulders while inhaling.

22. A multiparous client whose fundus is firm and midline at the umbilicus 8 hours after a vaginal birth tells the nurse that when she ambulated to the bathroom after sleeping for 4 hours, her dark red lochia seemed heavier. Which information would the nurse include when explaining to the client about the increased lochia on ambulation?

- ☐ 1. Her bleeding needs to be reported to the healthcare provider (HCP) immediately.
- ☐ 2. The increased lochia occurs from lochia pooling in the vaginal vault.

- ☐ 3. The increase in lochia may be an early sign of postpartum hemorrhage.
- ☐ 4. This increase in lochia usually indicates retained placental fragments.

23. A primiparous client who gave birth vaginally 8 hours ago desires to take a shower. The nurse anticipates remaining near the client to assess for which problem?

- ☐ 1. fatigue
- ☐ 2. fainting
- ☐ 3. diuresis
- ☐ 4. hygiene needs

24. A primiparous client who gave birth 12 hours ago under epidural anesthesia with a midline episiotomy tells the nurse that she is experiencing a great deal of discomfort when she sits in a chair with the baby. Which instructions would be **most** appropriate?

- ☐ 1. "Ask for some pain medication before you sit down."
- ☐ 2. "Squeeze your buttock muscles together before sitting down."
- ☐ 3. "Keep a relaxed posture before sitting down with your full weight."
- ☐ 4. "Ask the healthcare provider for some analgesic cream or spray."

25. Which information would the nurse include in the primiparous client's discharge teaching plan about measures to provide visual stimulation for the neonate?

- ☐ 1. Maintain eye contact while talking to the baby.
- ☐ 2. Paint the baby's room in bright colors accented with teddy bears.
- ☐ 3. Use brightly colored animals and cartoon figures on the wall.
- ☐ 4. Move a brightly colored rattle in front of the baby's eyes.

26. A primiparous client has just given birth to a healthy male infant. The client and her husband are Muslim, and the husband begins chanting a song while holding the neonate. How does the nurse interpret the father's actions?

- ☐ 1. thanking Allah for giving him a male heir
- ☐ 2. singing to his son from the Koran in praise of Allah
- ☐ 3. expressing appreciation that his wife and son are healthy
- ☐ 4. performing a ritual similar to baptism in other religions

27. An adolescent primiparous client 24 hours postpartum asks the nurse how often she can hold her baby without “spoiling” him. Which response would be **most** appropriate?

- ☐ 1. “Hold him when he is fussy or crying.”
- ☐ 2. “Hold him as much as you want to hold him.”
- ☐ 3. “Try to hold him infrequently to avoid overstimulation.”
- ☐ 4. “You can hold him periodically throughout the day.”

28. On the first postpartum day, the primiparous client reports perineal pain of 5 on a scale of 1 to 10 that was unrelieved by ibuprofen 800 mg given 2 hours ago. The nurse should further assess the client for:

- ☐ 1. puerperal infection.
- ☐ 2. vaginal lacerations.
- ☐ 3. history of drug abuse.
- ☐ 4. perineal hematoma.

29. The nurse assigns an unlicensed assistive personnel (UAP) to care for a client who is 1 day postpartum. Which tasks would be appropriate to delegate to this person? Select all that apply.

- ☐ 1. changing the perineal pad and reporting the drainage
- ☐ 2. teaching the mother to latch the infant onto the breast
- ☐ 3. checking the location of the fundus prior to ambulating the client
- ☐ 4. reinforcing good hygiene while assisting the client with washing the perineum
- ☐ 5. discussing postpartum depression with the client who is found crying
- ☐ 6. assisting the client with ambulation shortly after birth

30. While the nurse is caring for a primiparous client on the first postpartum day, the client asks, “How is that woman doing who lost her baby from prematurity? We were in labor together.” Which response by the nurse would be **most** appropriate?

- ☐ 1. Ignore the client’s question and continue with morning care.
- ☐ 2. Tell the client, “I’m not sure how the other woman is doing today.”
- ☐ 3. Tell the client, “I need to ask the woman’s permission before discussing her well-being.”

- ☐ 4. Explain to the client that “Nurses are not allowed to discuss other clients on the unit.”

31. A newly postpartum primiparous client asks the nurse, “Can my baby see?” Which statement about neonatal vision should the nurse include in the explanation?

- ☐ 1. Neonates primarily focus on moving objects.
- ☐ 2. They can see objects up to 12 inches (30.5 cm) away.
- ☐ 3. Usually they see clearly by about 2 days after birth.
- ☐ 4. Neonates primarily distinguish light from dark.

32. While assessing the fundus of a multiparous client 36 hours after birth of a term neonate, the nurse notes a separation of the abdominal muscles. The nurse should tell the client:

- ☐ 1. that she will have a surgical repair at 6 weeks postpartum.
- ☐ 2. to remain on bed rest until resolution occurs.
- ☐ 3. that the separation will resolve on its own with the right posture and diet.
- ☐ 4. to perform exercises involving head and shoulder raising in a lying position.

33. A postpartum client gave birth 6 hours ago without anesthesia and just voided 100 mL. The nurse palpates the fundus two fingerbreadths above the umbilicus and off to the right side. What should the nurse do **first**?

- ☐ 1. Administer ibuprofen.
- ☐ 2. Reassess in 1 hour.
- ☐ 3. Catheterize the client.
- ☐ 4. Obtain a prescription for a fluid bolus.

34. While the nurse is assessing the fundus of a multiparous client who gave birth 24 hours ago, the client asks, “What can I do to get rid of these stretch marks?” Which response would be **most** appropriate?

- ☐ 1. “As long as you do not get pregnant again, the marks will disappear completely.”
- ☐ 2. “They usually fade to a silvery-white color over a period of time.”
- ☐ 3. “You will need to use a specially prescribed cream to help them

disappear.”

☐ 4. “If you lose the weight you gained during pregnancy, the marks will fade to a pale pink.”

35. A primiparous client who gave vaginal birth to a viable term neonate 48 hours ago has a midline episiotomy and repair of a third-degree laceration. When preparing the client for discharge, which assessment would be **most** important?

- ☐ 1. constipation
- ☐ 2. diarrhea
- ☐ 3. excessive bleeding
- ☐ 4. rectal fistulas

36. In preparation for discharge, the nurse discusses sexual issues with a multiparous client who had a routine vaginal birth with a midline episiotomy. The client asked, “I’ve heard recommendations about when to resume intercourse have changed since my last baby. What are they saying now?” When should the nurse instruct the client that she can resume sexual intercourse?

- ☐ 1. in 6 weeks when the episiotomy is completely healed
- ☐ 2. after a postpartum check by the healthcare provider (HCP)
- ☐ 3. whenever the client is feeling amorous and desirable
- ☐ 4. when lochia flow and episiotomy pain have stopped

37. While caring for a multiparous client 4 hours after vaginal birth of a term neonate, the nurse notes that the mother’s temperature is 99.8°F (37.2°C), the pulse is 66 beats/min, and the respirations are 18 breaths/min. Her fundus is firm, midline, and at the level of the umbilicus. The nurse should:

- ☐ 1. continue to monitor the client’s vital signs.
- ☐ 2. assess the client’s lochia for large clots.
- ☐ 3. notify the client’s healthcare provider (HCP) about the findings.
- ☐ 4. offer the mother an ice pack for her forehead.

38. While assessing the episiotomy site of a primiparous client on the first postpartum day, the nurse observes a fairly large hemorrhoid at the client’s

rectum. After instructing the client about measures to relieve hemorrhoid discomfort, which client statement indicates the need for additional teaching?

- ☐ 1. "I should ask my healthcare provider about using a stool softener."
- ☐ 2. "Analgesic sprays and witch hazel pads can relieve the pain."
- ☐ 3. "I should lie on my back as much as possible to relieve the pain."
- ☐ 4. "I should drink lots of water and eat foods that have a lot of roughage."

39. A primiparous client is on a regular diet 24 hours postpartum. She is from Guatemala and speaks only Spanish. The client's mother asks the nurse if she can bring her daughter some "special foods from home." The nurse responds based on the understanding about which principle?

- ☐ 1. Foods from home are generally discouraged on the postpartum unit.
- ☐ 2. The mother can bring the daughter any foods that she desires.
- ☐ 3. This is permissible as long as the foods are nutritious and high in iron.
- ☐ 4. The client's healthcare provider (HCP) needs to give permission for the foods.

40. A primiparous client, 48 hours after a vaginal birth, is to be discharged with a prescription for vitamins with iron because she is anemic. To maximize absorption of the iron, the nurse instructs the client to take the medication with which liquid?

- ☐ 1. orange juice
- ☐ 2. herbal tea
- ☐ 3. milk
- ☐ 4. grape juice

41. The nurse is caring for a multiparous client after vaginal birth of a set of male twins 2 hours ago. The nurse should encourage the mother and partner to:

- ☐ 1. bottle-feed the twins to prevent exhaustion and fatigue.
- ☐ 2. plan for each parent to spend equal amounts of time with each twin.
- ☐ 3. avoid assistance from other family members until attachment occurs.
- ☐ 4. relate to each twin individually to enhance the attachment process.

42. Twelve hours after a vaginal birth with epidural anesthesia, the nurse palpates the fundus of a primiparous client and finds it to be firm, above the

umbilicus, and deviated to the right. What should the nurse do **next**?

- ☐ 1. Document this as a normal finding in the client's record.
- ☐ 2. Contact the healthcare provider (HCP) for a prescription for oxytocin.
- ☐ 3. Encourage the client to ambulate to the bathroom and void.
- ☐ 4. Gently massage the fundus to expel the clots.

43. A nurse is discussing discharge instructions with a client. Which statement indicates that the client understands the resources and information available if needed after discharge? Select all that apply.

- ☐ 1. "My fertility can return as early as 21 days after my baby's birth."
- ☐ 2. "I have the hospital phone number if I have any questions."
- ☐ 3. "If I have any breathing problems, chest pain, or pounding fast heart rate, I will seek medical assistance."
- ☐ 4. "My mother is coming to help for a month, so I will be fine."
- ☐ 5. "I know if I get fever or chills or change in lochia to call the healthcare provider."
- ☐ 6. "I will continue my prenatal vitamins until my postpartum checkup or longer."

The Postpartal Client Who Breast-feeds

44. The nurse is reviewing discharge instructions with a postpartum breast-feeding client who is going home. She has chosen depot medroxyprogesterone acetate (DMPA) as birth control. Which statement by the client identifies that she needs further instruction concerning birth control?

- ☐ 1. "I will wait for my 6-week checkup to get my first DMPA injection."
- ☐ 2. "DMPA injections last for 90 days."
- ☐ 3. "My milk supply should be well established before receiving a birth control injection."
- ☐ 4. "You will give me my first DMPA injection before I leave today."

45. A postpartum primiparous client is having difficulty breast-feeding her infant. The infant latches on to the breast, but the mother's nipples are extremely sore during and after each feeding. The client needs further

instruction about breast-feeding when she states:

- ☐ 1. "The baby needs to have as much of the nipple and areola in the mouth as possible to prevent sore and cracked nipples."
- ☐ 2. "I can put breast milk on my nipples to heal the sore areas."
- ☐ 3. "As long as some of my nipple is in the baby's mouth, the baby will receive enough milk."
- ☐ 4. "Feeding the baby for a half-hour on each side will not make my breasts sore."

46. The nurse is caring for a primipara who gave birth yesterday and has chosen to breast-feed her neonate. Which assessment finding is considered unusual for the client at this point postpartum?

- ☐ 1. milk production
- ☐ 2. diaphoresis
- ☐ 3. constipation
- ☐ 4. diuresis

47. The nurse is caring for several mother-baby couplets. In planning the care for each of the couplets, which mother would the nurse expect to have the **most** severe afterbirth pains?

- ☐ 1. G4, P1 client who is breast-feeding her infant
- ☐ 2. G3, P3 client who is breast-feeding her infant
- ☐ 3. G2, P2 cesarean client who is bottle-feeding her infant
- ☐ 4. G3, P3 client who is bottle-feeding her infant

48. A breast-feeding client is seen at home by the visiting nurse 10 days after a vaginal birth. The client has a warm, red, painful breast, a temperature of 100°F (37.7°C), and flu-like symptoms. What should the nurse do?

- ☐ 1. Encourage the client to breast-feed her infant using the unaffected breast.
- ☐ 2. Refer the woman to her healthcare provider (HCP).
- ☐ 3. Inform the client that she needs to discontinue breast-feeding.
- ☐ 4. Instruct the woman to apply warm compresses to the affected breast.

49. A diabetic postpartum client plans to breast-feed. The nurse determines that the client's understanding of breast-feeding instructions is

sufficient when she states:

- ☐ 1. "Insulin will be transferred to the baby through breast milk."
- ☐ 2. "Breast-feeding is not recommended for diabetic mothers."
- ☐ 3. "Breast milk from diabetic mothers contains few antibodies."
- ☐ 4. "Breast-feeding will assist in lowering maternal blood glucose."

50. A 1-day-old breast-fed infant has a bilirubin level that is at an intermediate risk for jaundice. Which statement by the infant's mother indicates an understanding of the teaching regarding jaundice?

- ☐ 1. "I should breast-feed my baby as often as possible."
- ☐ 2. "I should supplement with formula after every feeding."
- ☐ 3. "I should discontinue breast-feeding and change to formula feeding."
- ☐ 4. "I should place my baby in direct sunlight several times a day."

51. During a home visit, a breast-feeding client asks the nurse what contraception method she and her partner should use until she has her 6-week postpartal examination. Which method would be **most** appropriate for the nurse to suggest?

- ☐ 1. condom with spermicide
- ☐ 2. oral contraceptives
- ☐ 3. rhythm method
- ☐ 4. abstinence

52. A primiparous client who is beginning to breast-feed her neonate asks the nurse, "Is it important for my baby to get colostrum?" When instructing the client, the nurse would explain that colostrum provides the neonate with:

- ☐ 1. more fat than breast milk.
- ☐ 2. vitamin K, which the neonate lacks.
- ☐ 3. delayed meconium passage.
- ☐ 4. passive immunity from maternal antibodies.

53. Which principle forms the basis for the teaching plan about avoiding nonprescription medication for a primiparous client who is breast-feeding?

- ☐ 1. Breast milk quality and richness are decreased.
- ☐ 2. The mother's motivation to breast-feed is diminished.

- ☐ 3. Medications may be excreted in breast milk to the nursing neonate.
- ☐ 4. Medications interfere with the mother's letdown reflex.

54. A breast-feeding primiparous client with a midline episiotomy is prescribed ibuprofen 200 mg orally. The nurse instructs the client to take the medication:

- ☐ 1. before going to bed.
- ☐ 2. midway between feedings.
- ☐ 3. immediately after a feeding.
- ☐ 4. when providing supplemental formula.

55. A multiparous client, 28 hours after cesarean birth, who is breast-feeding has severe cramps or afterpains. The nurse explains that these are caused by:

- ☐ 1. flatulence accumulation after a cesarean birth.
- ☐ 2. healing of the abdominal incision after cesarean birth.
- ☐ 3. adverse effects of the medications administered after birth.
- ☐ 4. release of oxytocin during the breast-feeding session.

56. After the nurse counsels a primiparous, breast-feeding client about diet and nutritional needs during the lactation period, which client statement indicates a need for additional teaching?

- ☐ 1. "I need to increase my intake of vitamin D."
- ☐ 2. "I should drink at least five glasses of fluid daily."
- ☐ 3. "I need to get an extra 500 cal/day."
- ☐ 4. "I need to make sure I have enough calcium in my diet."

57. A breast-feeding primiparous client asks the nurse how breast milk differs from cow's milk. The nurse responds by saying that breast milk is higher in which nutrient?

- ☐ 1. fat
- ☐ 2. iron
- ☐ 3. sodium
- ☐ 4. calcium

58. While assisting a primiparous client with her first breast-feeding

session, which action should the nurse instruct the mother to do to stimulate the neonate to open the mouth and grasp the nipple?

- ☐ 1. Pull down gently on the neonate's chin, and insert the nipple.
- ☐ 2. Squeeze both of the neonate's cheeks simultaneously.
- ☐ 3. Place the nipple into the neonate's mouth on top of the tongue.
- ☐ 4. Brush the neonate's lips lightly with the nipple.

59. A 25-year-old primiparous client who gave birth 2 hours ago has decided to breast-feed her neonate. Which instructions should the nurse address as the highest **priority** in the teaching plan about preventing nipple soreness?

- ☐ 1. keeping plastic liners in the brassiere to keep the nipple drier
- ☐ 2. placing as much of the areola as possible into the baby's mouth
- ☐ 3. smoothly pulling the nipple out of the mouth after 10 minutes
- ☐ 4. removing any remaining milk left on the nipple with a soft washcloth

60. Which client statement indicates effective teaching about burping a breast-fed neonate?

- ☐ 1. "Breast-fed babies who are burped frequently will take more on each breast."
- ☐ 2. "If I supplement the baby with formula, I will rarely have to burp the baby."
- ☐ 3. "I will breast-feed my baby every 3 hours so I will not have to burp the baby."
- ☐ 4. "When I switch to the other breast, I will burp the baby."

61. After the nurse teaches a primiparous client planning to return to work in 6 weeks about storing breast milk, which client statement indicates the need for further teaching?

- ☐ 1. "I can safely store my milk at room temperature for 8 hours."
- ☐ 2. "I will be sure to label the milk with the date, time, and amount."
- ☐ 3. "I must discard any breast milk stored for more than 3 days in the refrigerator."
- ☐ 4. "I can keep the milk in a deep freeze in clean glass bottles for up to 1 year."

62. During a home visit on the fourth postpartum day, a primiparous client tells the nurse that she is aware of a “letdown sensation” in her breasts and asks what causes it. The nurse explains that the letdown sensation is stimulated by which hormone?

- ☐ 1. progesterone
- ☐ 2. estrogen
- ☐ 3. prolactin
- ☐ 4. oxytocin

63. During a home visit on the fourth postpartum day, a primiparous client tells the nurse that she has been experiencing breast engorgement. To relieve engorgement, the nurse teaches the client to use which intervention before nursing her baby?

- ☐ 1. Apply an ice cube to the nipples.
- ☐ 2. Rub her nipples gently with lanolin cream.
- ☐ 3. Express a small amount of breast milk.
- ☐ 4. Offer the neonate a small amount of formula.

64. A breast-feeding primiparous client who gave birth 8 hours ago asks the nurse, “How will I know that my baby is getting enough to eat?” Which guideline should the nurse include in the teaching plan as evidence of adequate intake?

- ☐ 1. six to eight wet diapers by the 5th day
- ☐ 2. three to four transitional stools on the 4th day
- ☐ 3. ability to fall asleep easily after feeding on the first day
- ☐ 4. regain of lost birth weight by the 3rd day

65. Which information should the nurse include in the teaching plan for a primiparous client who asks about weaning her neonate?

- ☐ 1. “Wait until you have breast-fed for at least 4 months.”
- ☐ 2. “Eliminate the baby’s favorite feeding times first.”
- ☐ 3. “Plan to omit the daytime feedings last.”
- ☐ 4. “Gradually eliminate one feeding at a time.”

66. A nurse is caring for a client who is 3 days postpartum and breast-feeding her baby girl. The following assessment is made by the nurse:

episiotomy area: red and edematous; breasts: firm and tender on palpation; fundus: firm 2 finger breaths below umbilicus. What nursing actions are indicated? Select all that apply.

- ☐ 1. Suggest the client apply cool compress to breasts.
- ☐ 2. Encourage the client to sit on a supportive device.
- ☐ 3. Ask the client how often the baby feeds.
- ☐ 4. Suggest the client take cool sitz baths twice a day.
- ☐ 5. Obtain specimen for culture and sensitivity from episiotomy site.

67. Two weeks after a breast-feeding primiparous client is discharged, she calls the birthing center and says that she is afraid she is “losing my breast milk. The baby had been nursing every 4 hours, but now she is crying to be fed every 2 hours.” The nurse interprets the neonate’s behavior as **most** likely caused by which factor?

- ☐ 1. lack of adequate intake to meet maternal nutritional needs
- ☐ 2. the mother’s fears about the baby’s weight gain
- ☐ 3. preventing the neonate from sucking long enough with each feeding
- ☐ 4. the neonate’s temporary growth spurt, which requires more feedings

68. During a home visit to a breast-feeding primiparous client at 1 week postpartum, the client tells the nurse that her nipples have become sore and cracked from the feedings. Which instruction should the nurse give the client?

- ☐ 1. Wipe off any lanolin creams from the nipple before each feeding.
- ☐ 2. Position the baby with the entire areola in the baby’s mouth.
- ☐ 3. Feed the baby less often for the next several days.
- ☐ 4. Use a mild soap while in the shower to prevent an infection.

69. A new father indicates he feels left out of the new family relationship since he is not able to bond the same way as the breast-feeding mother. What is the **most** appropriate response by the nurse?

- ☐ 1. “This is normal, and these feelings will go away within a few days.”
- ☐ 2. “Holding, talking to, and playing with the infant will facilitate bonding between baby and Dad.”
- ☐ 3. “Bonding occurs later in the first year of life, and Dad can become

involved when the infant is better able to recognize him.”

- ☐ 4. “Maternal infant bonding takes priority over paternal infant bonding.”

70. The triage nurse in the pediatrician’s office returns a call to a mother who is breast-feeding her 4-day-old infant. The mother is concerned about the yellow seedy stool that has developed since discharge home. What is the **best** reply by the nurse?

- ☐ 1. “This type of stool indicates the infant may have diarrhea and should be seen in the office today.”
- ☐ 2. “The stool will transition into a soft, brown, formed stool within a few days and is appropriate for breast-feeding.”
- ☐ 3. “The stool results from the gassy food eaten by the mother. Refrain from eating these foods while breast-feeding.”
- ☐ 4. “Soft seedy unformed stools with each feeding are normal for this age infant and will continue through breast-feeding.”

The Postpartal Client Who Bottle-feeds

71. The nurse is assessing a client at her postpartum checkup 6 weeks after a vaginal birth. The mother is bottle-feeding her baby. Which client finding indicates a problem at this time?

- ☐ 1. firm fundus at the symphysis
- ☐ 2. white, thick vaginal discharge
- ☐ 3. striae that are silver in color
- ☐ 4. soft breasts without milk

72. A client gave birth 2 days ago and has been given instructions on breast care for bottle-feeding mothers. Which statement indicates that the nurse should reinforce the instructions to the client?

- ☐ 1. “I will wear a sports bra or a well-fitting bra for several days.”
- ☐ 2. “When showering, I will direct water onto my shoulders.”
- ☐ 3. “I will use only water to clean my nipples.”
- ☐ 4. “I will use a breast pump to remove any milk that may appear.”

73. A 24-year-old primipara who has given birth to a healthy neonate plans to bottle-feed her neonate. What information regarding normal weight

gain should the nurse include in the teaching plan?

- ☐ 1. A baby normally loses 15% of weight before beginning to gain weight.
- ☐ 2. Adding rice cereal to the bottle is a good way to increase calories if weight gain is slow.
- ☐ 3. Gaining 30 g/day is a normal weight gain pattern.
- ☐ 4. Babies typically double birth weight by 3 months.

74. A primiparous client with a neonate who is 36 hours old asks the nurse, “Why does my baby spit up a small amount of formula after feeding?” The nurse explains that the regurgitation is thought to result from which factor?

- ☐ 1. an immature cardiac sphincter
- ☐ 2. a defect in the gastrointestinal system
- ☐ 3. burping the infant too frequently
- ☐ 4. moving the infant during the feeding

75. A primiparous client who will be bottle-feeding her neonate asks, “What is the **best** position for the baby after feeding?” Which position should the nurse recommend?

- ☐ 1. supine position
- ☐ 2. on the left side
- ☐ 3. prone without a pillow
- ☐ 4. sitting on the caregiver’s lap for 20 minutes

76. A primiparous client who is bottle-feeding her neonate asks, “When should I start giving the baby solid foods?” The nurse instructs the client to introduce solid foods no sooner than at which age?

- ☐ 1. 2 months
- ☐ 2. 6 months
- ☐ 3. 8 months
- ☐ 4. 10 months

77. After instructing a primiparous client who is bottle-feeding about burping, which client statement indicates that the client needs further teaching?

- ☐ 1. “I will burp him after 15 minutes of feeding him formula.”

- ☐ 2. “After he takes one-half ounce of formula, I will burp him.”
- ☐ 3. “I will burp him while he is in an upright position.”
- ☐ 4. “I will gently pat his back to get him to burp.”

78. When teaching a primiparous client about the growth and development of the neonate, the nurse should explain that **most** babies are able to drink independently from a sippy cup at what age?

- ☐ 1. 5 to 7 months
- ☐ 2. 8 to 10 months
- ☐ 3. 12 to 14 months
- ☐ 4. 15 to 16 months

The Postpartal Client with a Cesarean Birth

79. The nurse is assessing a cesarean section client who gave birth 12 hours ago. Findings include a distended abdomen with faint bowel sounds \times 1 quadrant, fundus firm at umbilicus, lochia scant, rubra, and pain rated 2 on a scale of 1 to 10. The IV and Foley catheter have been discontinued, and the client received medication 3 hours ago for pain. The client can have pain medication every 3 to 4 hours. The nurse should **first**:

- ☐ 1. give the client pain medication.
- ☐ 2. have the client use the incentive spirometry.
- ☐ 3. ambulate the client from the bed to the hallway and back.
- ☐ 4. encourage the client to begin caring for her baby.

80. Carboprost was injected into the uterus of a client to treat uterine atony during a cesarean section. In preparing to care for this client postpartum, the nurse should assess the client for which common adverse effects of the medication?

- ☐ 1. vertigo and confusion
- ☐ 2. nausea and diarrhea
- ☐ 3. restlessness and increased vaginal bleeding
- ☐ 4. headache and hypertension

81. A multigravida 30-year-old woman has given cesarean birth to a healthy term female neonate due to an abnormal fetal heart rate tracing. At 2

hours postpartum, the nurse assesses the client's Foley catheter and observes that the client's urine is slightly red-tinged. What should the nurse do **next**?

- ☐ 1. Continue to monitor the client's input and output.
- ☐ 2. Palpate the client's fundus gently every 15 minutes.
- ☐ 3. Assess the placement of the Foley catheter.
- ☐ 4. Contact the client's healthcare provider (HCP) for further instructions.

82. Four hours after cesarean birth of a neonate weighing 8 lb, 13 oz (4,000 g), the primiparous client asks, "If I get pregnant again, will I need to have a cesarean?" When responding to the client, the nurse should base the response to the client about vaginal birth after cesarean (VBAC) on which standard of practice?

- ☐ 1. VBAC may be possible if the client has not had a classic uterine incision.
- ☐ 2. A history of rapid labor is a necessary criterion for VBAC.
- ☐ 3. A low transverse incision contraindicates the possibility for VBAC.
- ☐ 4. VBAC is not possible because the neonate was large for gestational age.

83. A primiparous client who underwent a cesarean birth 30 minutes ago is to receive Rho (D) immune globulin (RhoGAM). The nurse should administer the medication within which time frame after birth?

- ☐ 1. 24 hours
- ☐ 2. 48 hours
- ☐ 3. 72 hours
- ☐ 4. 96 hours

84. While the nurse is caring for a primiparous client with cephalopelvic disproportion 4 hours after a cesarean birth, the client requests assistance in breast-feeding. To promote maximum maternal comfort, which position would be **most** appropriate for the nurse to suggest?

- ☐ 1. football hold
- ☐ 2. scissors hold
- ☐ 3. cross-cradle hold
- ☐ 4. cradle hold

The Postpartal Client with Complications

85. A multigravid client gave birth vaginally 2 hours ago. A family member notifies the nurse that the client is pale and shaky. Which are the **priority** assessments for the nurse to make?

- ☐ 1. Blood glucose and vital signs
- ☐ 2. Temperature and level of consciousness
- ☐ 3. Uterine infection and pain
- ☐ 4. fundus and lochia

86. A postpartum woman has unrelenting pain in her rectum after vaginal birth despite administration of pain medications. Which action is **most** indicated?

- ☐ 1. administering additional pain medications
- ☐ 2. assessing the perineum
- ☐ 3. reassuring the client that pain is normal after vaginal birth
- ☐ 4. preparing a warm sitz bath for the client

87. A multiparous client at 24 hours postpartum is found to have a swelling and pain in her right leg. She demonstrates a positive Homans sign with discomfort. The nurse should:

- ☐ 1. place a cold pack on the client's perineal area.
- ☐ 2. place the client in semi-Fowler's position.
- ☐ 3. notify the client's healthcare provider (HCP) immediately.
- ☐ 4. ask the client to ambulate around the room.

88. Prophylactic heparin therapy is prescribed to treat thrombophlebitis in a multiparous client who gave birth 24 hours ago. After instructing the client about the medication, the nurse determines that the client understands the instructions when she states which as the purpose of the drug?

- ☐ 1. to thin the blood clots
- ☐ 2. to increase the lochial flow
- ☐ 3. to increase the perspiration for diuresis
- ☐ 4. to prevent further blood clot formation

89. While caring for a the postpartum client who is receiving treatment

with bed rest and intravenous heparin therapy for a deep vein thrombosis, the nurse should contact the client's healthcare provider (HCP) immediately if the client exhibited which symptom?

- ☐ 1. pain in her calf
- ☐ 2. dyspnea
- ☐ 3. hypertension
- ☐ 4. bradycardia

90. A primiparous client 3 days postpartum is to be discharged on heparin therapy. After teaching her about possible adverse effects of heparin therapy, the nurse determines that the client needs further instruction when she states that the adverse effects include which symptom?

- ☐ 1. epistaxis
- ☐ 2. bleeding gums
- ☐ 3. slow pulse
- ☐ 4. petechiae

91. After being treated with heparin therapy for thrombophlebitis, a multiparous client who gave birth 4 days ago is to be discharged on oral warfarin. After teaching the client about the medication and possible effects, which client statement indicates successful teaching?

- ☐ 1. "I can take two aspirin if I get uterine cramps."
- ☐ 2. "Protamine sulfate should be available if I need it."
- ☐ 3. "I should use a soft toothbrush to brush my teeth."
- ☐ 4. "I can drink an occasional glass of wine if I desire."

92. A nurse is explaining basic principles of asepsis and infection control to a client who has a respiratory tract infection following birth. The nurse determines the client understands principles of infection control to follow when the client says:

- ☐ 1. "I must ask visitors to wear a mask."
- ☐ 2. "I must wear gloves when I handle my baby."
- ☐ 3. "I must use individual client care equipment."
- ☐ 4. "I must practice frequent handwashing."

93. The nurse is caring for a woman who gave birth vaginally 4 hours ago.

Which factors would likely contribute to the development of endometritis in this woman? Select all that apply.

- ☐ 1. manual removal of placenta
- ☐ 2. in-and-out catheterization during labor
- ☐ 3. epidural use
- ☐ 4. prolonged labor
- ☐ 5. placement of fetal scalp electrode

94. A postpartum multiparous client diagnosed with endometritis is to receive intravenous antibiotic therapy with ampicillin. Before administering this drug, the nurse must take which action?

- ☐ 1. Ask the client if she has any drug allergies.
- ☐ 2. Assess the client's pulse rate.
- ☐ 3. Place the client in a side-lying position.
- ☐ 4. Check the client's perineal pad.

95. Which intervention would be **most** important for the nurse to encourage in a primiparous client diagnosed with endometritis who is receiving intravenous antibiotic therapy?

- ☐ 1. Ambulate to the bathroom frequently.
- ☐ 2. Discontinue breast-feeding temporarily.
- ☐ 3. Maintain bed rest in Fowler's position.
- ☐ 4. Restrict visitors to prevent contamination.

96. Which measure would the nurse expect to include in the teaching plan for a multiparous client who gave birth 24 hours ago and is receiving intravenous antibiotic therapy for cystitis?

- ☐ 1. Limiting fluid intake to 1 L daily to prevent overload
- ☐ 2. Emptying the bladder every 2 to 4 hours while awake
- ☐ 3. Washing the perineum with povidone-iodine after voiding
- ☐ 4. Avoiding the intake of acidic fruit juices until the treatment is discontinued

97. A primiparous client diagnosed with cystitis at 48 hours postpartum who is receiving intravenous ampicillin asks the nurse, "Can I still continue to breast-feed my baby?" The nurse should tell the client:

- ☐ 1. "You can continue to breast-feed as long as you want to do so."
- ☐ 2. "Alternate your breast-feeding with formula feeding to help you rest."
- ☐ 3. "You will need to discontinue breast-feeding until the antibiotic therapy is stopped."
- ☐ 4. "You will need to modify your technique by manually pumping your breasts."

98. Four days after a vaginal birth, a client has excessive lochia rubra with clots. The healthcare provider (HCP) prescribes carboprost 0.25 mg intramuscularly. Which statement by the client reflects the need for more teaching about carboprost?

- ☐ 1. "This medication may cause nausea and vomiting."
- ☐ 2. "This medication sometimes causes hypotension that leads to dizziness."
- ☐ 3. "I will also receive medication to help prevent severe diarrhea."
- ☐ 4. "I may run a fever after being treated with carboprost."

99. During the first hour postpartum, assessment of a multiparous client who gave cesarean birth to a neonate weighing 10 lb, 2 oz (4,593 g) reveals a soft fundus with excessive lochia rubra. The nurse should include which interventions in the client's plan of care?

- ☐ 1. administration of intravenous oxytocin
- ☐ 2. placement of the client in a side-lying position
- ☐ 3. rigorous fundal massage every 5 minutes
- ☐ 4. preparation for an emergency hysterectomy

100. A primiparous client who was diagnosed with hydramnios and breech presentation while in early labor is diagnosed with early postpartum hemorrhage at 1 hour after a cesarean birth. The client asks, "Why am I bleeding so much?" The nurse responds based on the understanding that the **most** likely cause of uterine atony in this client is which factor?

- ☐ 1. trauma during labor and birth
- ☐ 2. moderate fundal massage after birth
- ☐ 3. lengthy and prolonged second stage of labor
- ☐ 4. overdistention of the uterus from hydramnios

101. Thirty-six hours after a vaginal birth, a multiparous client is diagnosed with endometritis. When assessing the client, which symptom would the nurse expect to find?

- ☐ 1. profuse amounts of lochia
- ☐ 2. abdominal distention
- ☐ 3. nausea and vomiting
- ☐ 4. fever greater than 100.4°F (38.0°C)

102. A multiparous client visits the urgent care center 5 days after a vaginal birth, experiencing persistent lochia rubra in a moderate to heavy amount. The client asks the nurse, “Why am I continuing to bleed like this?” The nurse should instruct the client that this type of postpartum bleeding is **most** likely caused by which problem?

- ☐ 1. uterine atony
- ☐ 2. cervical lacerations
- ☐ 3. vaginal lacerations
- ☐ 4. retained placental fragments

103. A 26-year-old primiparous client is seen in the urgent care clinic 2 weeks after giving birth to a viable female neonate. The client, who is breast-feeding, is diagnosed with mastitis of the right breast. The client asks the nurse, “Can I continue breast-feeding?” The nurse should tell the client:

- ☐ 1. “You can continue to breast-feed, feeding your baby more frequently.”
- ☐ 2. “You can continue once your symptoms begin to decrease.”
- ☐ 3. “You must discontinue breast-feeding until antibiotic therapy is completed.”
- ☐ 4. “You must stop breast-feeding because the breast is contaminated.”

104. A primiparous client who had a vaginal birth 1 hour ago voices anxiety because she has a nephew with Down syndrome. After teaching the client about Down syndrome, which client statement indicates the need for additional teaching?

- ☐ 1. “Down syndrome is an abnormality that can result from a missing chromosome.”
- ☐ 2. “Down syndrome usually results in some degree of mental

retardation.”

- ☐ 3. “There are several methods available to determine whether my baby has Down syndrome.”
- ☐ 4. “Older mothers are more likely to have a baby with chromosomal abnormalities.”

105. A 15-year-old unmarried primiparous client is being cared for in the hospital’s birthing center after vaginal birth of a viable neonate. The neonate is being placed for adoption through a social service agency. Four hours postpartum, the client asks if she can feed her baby. Which of the response would be **most** appropriate?

- ☐ 1. “I will bring the baby to you for feeding.”
- ☐ 2. “I think we should ask your healthcare provider (HCP) if this is a good idea.”
- ☐ 3. “It is not a good idea for you to have any contact with the baby.”
- ☐ 4. “I will check with the social worker to see if the adopting parents will permit this.”

106. After teaching a primiparous client about treatment and self-care of mastitis of the right breast, the nurse determines that the client needs further instruction when she makes which statement?

- ☐ 1. “I can apply localized heat to the infected area.”
- ☐ 2. “I should increase my fluid intake to 2,000 mL/day.”
- ☐ 3. “I will need to take antibiotics for 7 to 10 days before I am cured.”
- ☐ 4. “I should begin breast-feeding on the right side to decrease the pain.”

107. During a home visit to a primiparous client who gave birth vaginally 14 days ago, the client says, “I have been crying a lot the last few days. I just feel so awful. I am a rotten mother. I just do not have any energy. Plus, my husband just got laid off from his job.” The nurse observes that the client’s appearance is disheveled. What would be the nurse’s **best** response?

- ☐ 1. “These feelings commonly indicate symptoms of postpartum blues and are normal. They will go away in a few days.”
- ☐ 2. “I think you are probably overreacting to the labor and birth process. You are doing the best you can as a mother.”
- ☐ 3. “It is not unusual for some mothers to feel depressed after the birth of a

baby. I think I should contact your healthcare provider.”

☐ 4. “This may be a symptom of a serious mental illness. I think you should probably go to the hospital.”

108. A teen client, who is 1 week postpartum, is concerned about the possibility of postpartum depression because she has a history of depression. Which comment by the client would indicate that she understood the nurse’s teaching about the postpartum period and her risks for postpartum depression?

☐ 1. “Sleep should not be too much of a problem because the baby will soon start to sleep through the night.”

☐ 2. “Since I am breast-feeding, I can eat all the food I want and not feel fat. The baby will use all the calories.”

☐ 3. “If I am feeling guilty or not capable of caring for the baby and am not sleeping or eating well, I need to contact the office.”

☐ 4. “I am going to give the baby the best care possible without asking anyone for help to show all those people who think I cannot do it.”

Managing Care, Quality, and Safety of Postpartal Clients

109. The nurse is catheterizing a client who cannot void after a normal birth 8 hours ago. The nurse begins the catheterization process, and the client states, “I forgot to tell the nurse I get hives to betadine.” The nurse should take which steps in order of priority from first to last? All options must be used.

1. Document the incident.

2. Clean povidone-iodine from the client’s vaginal area.

3. Notify the healthcare provider (HCP) prescribing catheterization.

4. File an incident report.

110. A nurse is walking down the hall in the main corridor of a hospital when the infant security alert system sounds and a code for an infant abduction is announced. The **first** responsibility of the nurse when this situation occurs is to take which action?

- ☐ 1. Move to the entrance of the hospital, and check each person leaving.
- ☐ 2. Go to the obstetrics unit to determine if they need help with the situation.
- ☐ 3. Call the nursery to ask which baby is missing.
- ☐ 4. Observe individuals in the area for large bags or oversized coats.

111. The nurse on a mother-baby unit who is working on the night shift is revising the planning worksheet for the remaining 2 hours of the shift. The nurse has tasks and prescriptions to complete prior to the change of shift at 0700. Using the work plan below, how should the nurse organize the tasks from first to last so that everything is completed by 0700? All options must be used.

1. Draw blood for the prescribed laboratory tests (complete blood counts [CBCs]) on three postpartum clients with report on medical records by shift change.

2. Start IV of D5 ½ NS at keep vein open (KVO) rate on postpartum client just prior to change of shift.

3. Complete admission assessment of newborn turned over to nurse at 0500.

4. Draw newborn bilirubin level at 0600.

Nurse Worksheet

0500	
0530	
0600	
0630	

112. A nurse is caring for a woman who gave birth to her baby boy 2 hours ago. The nurse notes the woman's perineal pad contains some small clots and a moderate amount of lochia has accumulated under her buttocks. What is the **first** action the nurse should take at this time?

- ☐ 1. Request a prescription to administer oxytocin.
- ☐ 2. Perform an in-and-out catheter immediately.
- ☐ 3. Measure blood loss by measuring perineal pad.
- ☐ 4. Check fundus for position and consistency.

113. The nurse is reviewing the laboratory values on the medical record of a woman who is postpartum day 2. (See Exhibit.)

History	Physical	Labs	Prescriptions
Value	Traditional Units	SI Units	
WBC	18,000	18 x/L	
Hematocrit	40%	0.40%	
Hemoglobin	9 g/dL	90 g/L	
Platelets	400,000	40 x/L	

Based on this information, the nurse should:

- ☐ 1. contact the healthcare provider (HCP).
- ☐ 2. obtain a prescription for intravenous antibiotics.
- ☐ 3. assess the woman's vital signs.
- ☐ 4. prepare to administer pain medication.

114. The nurse assesses a client, who delivered vaginally 6 days ago, during a home visit. Which finding should the nurse report immediately to the healthcare provider (HCP)? Select all that apply.

- ☐ 1. foul-smelling lochia
- ☐ 2. engorged breasts bilaterally
- ☐ 3. client who cries easily
- ☐ 4. soaking 1 peripad every 3 to 4 hours
- ☐ 5. temperature of 100.8°F (38.2°C)

115. The night nurse has completed the change of shift report. As the day nurse makes rounds on a postpartum client receiving magnesium sulfate, it is noted the client developed significantly elevated blood pressure during the past shift. Further assessment reveals the magnesium sulfate rate is infusing well below the prescribed rate. In addition to adjusting the infusion rate and notifying the healthcare provider (HCP), what is the **most** important action by the nurse?

- ☐ 1. Complete an incident report.

- ☐ 2. Discuss the matter with the nurse the next time she works.
- ☐ 3. Ask the charge nurse if an incident report is necessary.
- ☐ 4. Evaluate the client's BP for 4 hours before making a decision.

116. The nurse is serving on the Quality Improvement Committee for the maternity unit. Quality improvement projects for this unit impacting safety and quality of care include which projects? Select all that apply.

- ☐ 1. use of recycling bins on the unit
- ☐ 2. infant identification system
- ☐ 3. sibling and family visitation policies
- ☐ 4. postpartum discharge instructions
- ☐ 5. rooming in guidelines

117. A nurse working on the postpartum unit is asked to participate in the unit Client Safety Committee. The nurse wants to know what type of projects would be conducted for the unit. Select all that apply.

- ☐ 1. prevention of infant abduction
- ☐ 2. safe medication administration
- ☐ 3. adequate nourishment on unit
- ☐ 4. proper restraints during procedures
- ☐ 5. maternal/infant identification system

118. A nurse who works on an obstetrical inpatient unit has been assigned to the client safety committee. What client safety goals are **most** applicable to this setting? Select all that apply.

- ☐ 1. effective and timely "hand-off reports" between labor and birth staff and mother-baby staff
- ☐ 2. ensuring that preprocedure verifications are completed by healthcare providers (HCP) for any invasive procedure
- ☐ 3. involving clients in education to cord infections
- ☐ 4. identification of safety risks specific to the unit, such as infant abduction
- ☐ 5. car seat instruction allowing infants to ride facing backward in the front seat

119. The nurse is making a postpartum visit at the home of a client who

delivered 14 days earlier. After assessing the vital signs (temperature, 99°F (37.2°C); pulse, 88 beats/min; respiration rate, 20 breaths/min; and blood pressure, 112/60 mm Hg), the nurse records other findings as follows:

Breasts	Heart	Lungs	Abdomen
Soft + Firm – Nipples intact + Cracks – Blisters –	Regular rate, 88	Clear +	Soft + Distended – Bowel sounds + Fundus firm + Midline + 4 CM↓U Nontender + Bladder empty +

Perineum	Lochia	Extremities
Midline episiotomy redness – Ecchymosis – Edema – Discharge – Approximated + Hemorrhoids –	Serosa scant	Legs: 1+ ankle edema Redness – Tenderness – Homans –

Which finding indicates delayed involution?

- ☐ 1. vital signs
- ☐ 2. fundus
- ☐ 3. lochia
- ☐ 4. edema of the ankles

Answers, Rationales, and Test-Taking Strategies

*The answers and rationales for each question follow below, along with keys (🔑) to the client need (CN) and cognitive level (CL) for each question. In addition, you will also see a glossary icon (📖) highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 12–23 and pages 35–36 in Part 1 of this book.*

The Postpartal Client with a Vaginal Birth

1. 4. The hospital identification procedures for mothers and infants need to be completed each time a newborn is returned to a family's room. It does not matter how well the nurse knows the mother and infant; this validation is a standard of care in an obstetrical setting. Assessing the mother's ability to ambulate, asking the mother if there is anything else she needs to care for the infant, and checking the crib to determine if there are enough supplies are important steps that are part of the process of transferring a baby to the mother, but identification verification is a safety measure that must occur first.

🔑 CN: Safety and infection control; CL: Create

2. 3. At any point in the postpartum period, the lochia should be dark in color, rather than bright red. The volume should not be great enough to trickle or run from the vagina. The information provided states the fundus is firm, midline, and at the umbilicus, which are the expected outcomes at this point postpartum. These findings would indicate to the nurse that the bleeding is not coming from the uterus or from uterine atony. The bladder is not palpable, which indicates that the bleeding is not related to a full bladder, which is further validated by the fundus being at the umbilicus. The most likely etiology is cervical or vaginal lacerations or tears. The nurse is unable to do anything to stop this type of bleeding and must notify the **HCP** 📖. Increasing the IV rate will not decrease the amount or type of vaginal

bleeding. Rechecking the hematocrit and hemoglobin will only provide background information for the nurse and identify the beginning levels for this mother, rather than where she is now. It will do nothing to stop the bleeding. The bleeding level and color is not normal, and documenting such findings as normal is incorrect.

CN: Management of care; CL: Synthesize

3. 4. Within the first 24 hours postpartum, maternal temperature may increase to 100.4°F (38°C), a normal postpartum finding attributed to dehydration. A temperature above 100.4°F (38°C) after the first 24 hours indicates a potential for infection. The hemoglobin is in the normal range. WBC count is normally elevated as a response to the inflammation, pain, and stress of the birthing process. A pulse rate of 60 beats/min is normal at this period and results from an increased cardiac output (mobilization of excess extracellular fluid into the vascular bed, decreased pressure from the uterus on vessels, blood flow back to the heart from the uterus returning to the central circulation) and alteration in stroke volume.

CN: Physiological adaptation; CL: Analyze

4. 1,2,3,5. Outcome evaluation for a family about 7 days after birth would include a mother who is tired but is able to care for herself and her baby. Having adequate support systems enables the mother to care better for herself and family members, as they can provide the backup for situations that may arise and a resource for new families. The normal progression for lochia is to change from red to pink to off-white while decreasing in amount. This is within the usual time periods for a postpartum mother. The baby should be feeding more frequently than every 6 to 8 hours. It is expected that a 7-day-old infant feeds every 3 to 4 hours if bottle-feeding and every 1½ to 3 hours if breast-feeding. Follow-up questions the nurse would ask to further evaluate this situation include “How many wet diapers does the infant have daily? How alert is the infant? Did the infant gain any weight at the first checkup?” It is expected that the mother has positive comments about the infant, but the nurse will evaluate to determine if there is at least one positive comment.

CN: Management of care; CL: Evaluate

5. 2. Pain medication is the first strategy to initiate at this pain level. When

trauma has occurred to any area, the usual intervention is ice for the first 24 hours and heat after the first 24 hours. Sitz baths are initiated at the conclusion of ice therapy. Ice has already been initiated and will prevent further edema to the rectal sphincter and perineum and continue to reduce some of the pain. Anesthetic sprays can also be utilized for the perineal area when pain is involved but would not lower the pain to a level that the client considers tolerable.

CN: Physiological adaptation; CL: Synthesize

6. 2. Educating the client about caring for herself and her infant are the two highest priority goals. Following childbirth, all mothers, especially the primigravida, require instructions regarding self-care and infant care. Learning needs should be assessed in order to meet the specific needs of each client. Bonding is significant, but is only one aspect of the needs of this client, and the bonding process would have been implemented immediately postpartum, rather than waiting 2 hours. Planning the discharge occurs after the initial education has taken place for mother and infant and the nurse is aware of any need for referrals. Safety is an aspect of education taught continuously by the nurse and should include maternal as well as newborn safety.

CN: Management of care; CL: Create

7. 3. The client is in the taking hold phase with a demonstrated focus on the neonate and learning about and fulfilling infant care and needs. The taking in phase is the first period after birth where there is emphasis on reviewing and reliving the labor and birth process, concern with self, and needing to be mothered. Eating and sleep are high priorities during this phase. Taking on is not a phase of postpartum psychological adaptation. Letting go is the process beginning about 6 weeks postpartum when the mother may be preparing to go back to work. During this time, she can have other individuals assume care of the infant and begin the separation process.

CN: Psychosocial integrity; CL: Analyze

8. 1. A urine toxicology screening will be collected to document that the infant has been exposed to illegal drug use. This documentation will be the basis for legal action for the protection of this infant. If the infant tests

positive for cocaine, the legal system will be activated to provide and ensure protective custody for this child. Hospital security would not become involved unless the mother is obtaining or using drugs on hospital premises. The mother and infant have the same privileges as do any hospitalized clients unless the safety of the infant is jeopardized; thus, limiting contact with visitors would not be appropriate. Local law enforcement agencies would be contacted only if the mother initiates use of drugs on hospital premises, and such contact would be made through the hospital security system.

CN: Physiological adaptation; CL: Synthesize

9. 4. Acetaminophen and hydrocodone would be the drug of choice for this situation because the pain level is so high. Aspirin is not usually used because of the bleeding risk associated with its use. Although ibuprofen would typically be a good choice because it inhibits the prostaglandin synthesis associated with a multiparous client breast-feeding, the pain level is too high for this drug to have an acceptable effect. Docusate is used as a stool softener postpartum but does not provide pain relief.

CN: Pharmacological and parenteral therapies; CL: Synthesize

10. 1. Immediately after delivery of the placenta, the nurse would expect to palpate the fundus halfway between the umbilicus and the symphysis pubis. Within 2 hours postpartum, the fundus should be palpated at the level of the umbilicus. The fundus remains at this level or may rise slightly above the umbilicus for approximately 12 hours. After the first 12 hours, the fundus should decrease one fingerbreadth (1 cm) per day in size. By the 9th or 10th day, the fundus usually is no longer palpable.

CN: Health promotion and maintenance; CL: Apply

11. 2. The instillation of erythromycin into the neonate's eyes provides prophylaxis for ophthalmia neonatorum, or neonatal blindness caused by gonorrhea in the mother. Erythromycin is also effective in the prevention of infection and conjunctivitis from *Chlamydia trachomatis*. The medication may result in redness of the neonate's eyes, but this redness will eventually disappear. Erythromycin ointment is not effective in treating neonatal chorioretinitis from cytomegalovirus. No effective treatment is available for a mother with cytomegalovirus. Erythromycin ointment is not effective in

preventing cataracts. Additionally, neonatal infection with beta-hemolytic streptococcus results in pneumonia, bacterial meningitis, or death. Cataracts in the neonate may be congenital or may result from maternal exposure to rubella. Erythromycin ointment is also not effective for preventing and treating strabismus (crossed eyes). Infants may exhibit intermittent strabismus until 6 months of age.

CN: Pharmacological and parenteral therapies; CL: Apply

12. 3. Vitamin K acts as a preventive measure against neonatal hemorrhagic disease. At birth, the neonate does not have the intestinal flora to produce vitamin K, which is necessary for coagulation. Hypoglycemia is prevented and treated by feeding the infant. Hyperbilirubinemia severity can be decreased by early feeding and passage of meconium to excrete the bilirubin. Hyperbilirubinemia is treated with phototherapy. Polycythemia may occur in neonates who are large for gestational age or postterm. Clamping of the umbilical cord before pulsations cease reduces the incidence of polycythemia. Generally, polycythemia is not treated unless it is extremely severe.

CN: Pharmacological and parenteral therapies; CL: Apply

13. 1. The client has a hematoma. During the first 24 hours postpartum, ice packs can be applied to the perineal area to reduce swelling and discomfort. Ice packs usually are not effective after the first 24 hours. Although vital signs, including temperature, are important assessments, taking the client's temperature is unrelated to the hematoma and would provide no additional information about swelling. After 24 hours, the client may obtain more relief by taking a warm sitz bath. This moist heat is an effective way to increase circulation to the perineum and provide comfort. Usually, hematomas resolve without further treatment within 6 weeks. Additionally, the nurse should measure the hematoma to provide a baseline for subsequent measurements and should notify the **HCP**  of its presence. An antibiotic is not warranted at this point because the client is not exhibiting any signs or symptoms of infection.

CN: Health promotion and maintenance; CL: Synthesize

14. 4. Urinary retention soon after childbirth is usually caused by edema

and trauma of the lower urinary tract; this commonly results in difficulty with initiating voiding. Hyperemia of the bladder mucosa also commonly occurs. The combination of hyperemia and edema predisposes to decreased sensation to void, overdistention of the bladder, and incomplete bladder emptying. A prolonged first stage of labor can contribute to exhaustion and uterine atony, not urinary retention. If the client had a urinary tract infection, she would exhibit symptoms such as dysuria and a burning sensation. After birth, the uterus is contracting, which leads to less pressure on the bladder. Pressure of the uterus on the bladder occurs during labor.

CN: Health promotion and maintenance; CL: Analyze

15. 2. For clients who are bottle-feeding, the menstrual flow should return in 6 to 10 weeks, after a rise in the production of follicle-stimulating hormone by the pituitary gland. Nonlactating mothers rarely ovulate before 4 to 6 weeks postpartum. Therefore, 3 to 4 weeks is too early for the menstrual cycle to resume. For women who are breast-feeding, the menstrual flow may not return for 3 to 4 months (12 to 16 weeks) or, in some women, for the entire period of lactation, because ovulation is suppressed.

CN: Health promotion and maintenance; CL: Apply

16. 4. The client's dizziness is most likely caused by orthostatic hypotension secondary to the decreased volume of blood in the vascular system resulting from the physiologic changes occurring in the mother after birth. The client is experiencing dizziness because not enough blood volume is available to perfuse the brain. The nurse should first allow the client to "dangle" on the side of the bed for a few minutes before attempting to ambulate. By 6 hours postpartum, the effects of the anesthesia should be worn off completely. Typically, the effects of epidural anesthesia wear off by 1 to 2 hours postpartum, and the effects of local anesthesia usually disappear by 1 hour. The client scenario provides no information to indicate that the client experienced any postpartum hemorrhage. Normal blood loss during birth should not exceed 500 mL.

CN: Health promotion and maintenance; CL: Apply

17. 4. Because the diet of immigrants from Mexico and Central America commonly includes beans, corn products, tomatoes, chili peppers, potatoes,

milk, cheeses, and eggs, the nurse needs to encourage an intake of meats, dark green leafy vegetables, and other high-protein products that are rich in iron. Doing so helps to compensate for the significant blood loss and subsequent iron loss that occurs during the postpartum period. Additionally, fresh fruits, meats, and green leafy vegetables may be scarce, possibly resulting in deficiencies of vitamin A, vitamin D, and iron. Tomatoes are high in vitamin C, potatoes are good sources of carbohydrates and vitamin C, and corn products are high in thiamine, but these are not rich sources of iron.

CN: Health promotion and maintenance; CL: Create

18. 4. A small, constant trickle of blood and a firm fundus are usually indicative of a vaginal tear or cervical laceration. If the client had retained placental tissue, the fundus would fail to contract fully (uterine atony), exhibiting as a soft or boggy fundus. Also, vaginal bleeding would be evident. Uterine inversion occurs when the uterus is displaced outside of the vagina and is obvious on inspection. Bladder distention may result in uterine atony because the pressure of the bladder displaces the fundus, preventing it from fully contracting. In this case, the fundus would be soft, possibly boggy, and displaced from midline.

CN: Reduction of risk potential; CL: Analyze

19. 4. On about the 11th postpartum day, the lochia should be lochia alba, clear or white in color. Lochia rubra, which is dark red to red, may persist for the first 2 to 3 days postpartum. From day 3 to about day 10, lochia serosa, which is pink or brown, is normal.

CN: Health promotion and maintenance; CL: Evaluate

20. 2. The nurse should instruct the client to cleanse the perineal area with warm water and to wipe from front to back with a blotting motion. Warm water is soothing to the tender tissue, and wiping from front to back reduces the risk of contamination. Hot, sudsy water may increase the client's discomfort and may even burn the client in a very tender area. After the first 24 hours, warm water sitz baths taken three or four times a day for 20 minutes can help increase circulation to the area. Ice packs are helpful for the first 24 hours.

CN: Health promotion and maintenance; CL: Evaluate

21. 3. After an uncomplicated birth, postpartum exercises may begin on the first postpartum day with exercises to strengthen the abdominal muscles. These are done in the supine position with the knees flexed, inhaling deeply while allowing the abdomen to expand and then exhaling while contracting the abdominal muscles. Exercises such as sit-ups (sitting, then lying back, and returning to a sitting position) and push-ups or exercises involving reaching for the knees are ordinarily too strenuous for the first postpartum day. Sit-ups may be done later in the postpartum period, after approximately 3 to 6 weeks.

CN: Health promotion and maintenance; CL: Apply

22. 2. Lochia can be expected to increase when the client first ambulates. Lochia tends to pool in the uterus and vagina when the client is recumbent and flows out when the client arises. If the client had reported that her lochia was bright red, the nurse would suspect bleeding. In this situation, the client would be put back in bed and the **HCP**  would be notified. Early postpartum hemorrhage occurs during the first 24 hours, but typically the fundus is soft or “boggy.” The client’s fundus here is firm and midline. Late postpartal hemorrhage, occurring after the first 24 hours, is usually caused by retained placental fragments or abnormal involution of the placental site.

CN: Health promotion and maintenance; CL: Synthesize

23. 2. Clients sometimes feel faint or dizzy when taking a shower for the first time after birth because of the sudden change in blood volume in the body. Primarily for this reason, the nurse remains nearby while the client takes her first shower after birth. If the client becomes dizzy or expresses symptoms of feeling faint, the nurse should get the client back to bed as soon as possible. If the client faints while in the shower, the nurse should cover the client to protect her privacy, stay with the client, and call for assistance. Fatigue postpartum is common and will precede taking a shower. Diuresis is a normal physiologic response during the postpartum period and not associated with showering. Hygiene needs also precede the shower.

CN: Safety and infection control; CL: Analyze

24. 2. The nurse should instruct the client to squeeze or contract the muscles of the buttocks together before sitting down in the chair; this

contracts the pelvic floor muscles, which reduces the tension on the tender perineal area. Then the client should put her full weight slowly down on the chair. Pain medication may only be prescribed for every 3 to 4 hours, so the client may not be able to receive pain medication every time she desires to sit in the chair. The episiotomy pain usually fades by the 5th or 6th postpartum day. Maintaining a relaxed posture before sitting does not contract the pelvic floor muscles. Most **healthcare providers (HCPs)**  prescribe an analgesic cream or spray when a client has an episiotomy, but they provide only temporary relief.

CN: Health promotion and maintenance; CL: Synthesize

25. 1. Neonates like to look at eyes, and eye-to-eye contact is a highly effective way to provide visual stimulation. The parent's eyes are circular, move from side to side, and become larger and smaller. Neonates have been observed to fix on them. In general, neonates prefer circular objects of darkness against a white background. Sharp black and white images of geometric figures are appropriate. Use of bright colors on the walls and moving a colorful rattle do not provide as much visual stimulation as eye-to-eye contact with talking. Brightly colored animals and cartoon figures are more appropriate at approximately 1 year of age.

CN: Health promotion and maintenance; CL: Create

26. 2. The father is praying to Allah because of the Muslim belief that the first sounds a child hears should be from the Koran in praise of and supplication to Allah. Although male children are revered in this culture, this practice is performed by Muslims whether the child is male or female. The father's actions are unrelated to his wife and son's being healthy. The nurse should allow the practice because doing so demonstrates cultural sensitivity and builds a trusting relationship with the family. The Muslim faith does not have a baptism rite whereby the child becomes a member of the faith.

CN: Health promotion and maintenance; CL: Analyze

27. 2. According to Erikson, infants are in the trust versus mistrust stage. Holding, talking to, singing to, and patting neonates helps them develop trust in caregivers. Tactile stimulation is important and should be encouraged. Holding neonates often is unlikely to spoil them because they are totally

dependent on other human beings to meet their needs. Being held makes infants feel loved and cared for and should be encouraged. The mother can hold the neonate as often as she wants, not just when the baby is crying or fussy. Overstimulation typically does not result from holding an infant.

CN: Health promotion and maintenance; CL: Synthesize

28. 4. If the client continues to have perineal pain after an analgesic medication has been given, the nurse should inspect the client's perineum for a hematoma because this is the usual cause of such discomfort. Ibuprofen is a nonsteroidal anti-inflammatory medication used to relieve mild pain. Pain from a perineal hematoma can be moderate to severe, possibly requiring a stronger analgesic, such as acetaminophen with codeine). Ice applied to the perineum during the first 24 hours postpartum may decrease the severity of hematoma formation. Application of warm heat, such as a sitz bath 3 times daily for 20 minutes, also can help to relieve the discomfort when implemented after the first 24 hours. Typically, hematomas resolve themselves within 6 weeks. A puerperal infection would be indicated if the client's temperature were 100.4°F (41°C) or higher. Also, lochia most likely would be foul smelling. A continuous trickle of lochia rubra would suggest a possible vaginal laceration. No evidence is presented to suggest a history of drug abuse.

CN: Reduction of risk potential; CL: Analyze

29. 1,4,6. Delegating care to **UAP**  requires that the nurse knows which tasks are within that individual's capability. Changing the perineal pad and reporting drainage, reinforcing hygiene with perineal care, and assisting with ambulation are within the individual's capacity. UAP should never be asked to complete any assessments, such as checking fundal location or performing skilled procedures on a client. In addition, it would be beyond the scope of the job of UAP to conduct client teaching such as teaching the mother how to latch or discussing postpartum depression with the client.

CN: Management of care; CL: Synthesize

30. 4. Legal regulations and ethical decision making require that the nurse maintain confidentiality at all times. The nurse's best response is to explain to the client that nurses are not allowed to discuss other clients on the unit.

Ignoring the client's question is inappropriate because doing so would interfere with the development of a trusting nurse-client relationship. Confidentiality must be maintained at all times. Telling the client that the nurse is not sure may imply that the nurse will find out and then tell the client about the other woman. Asking the other woman's permission to discuss her with another client is inappropriate because confidentiality must be maintained at all times.

 CN: Management of care; CL: Apply

31. 2. The neonate has immature oculomotor coordination, an inability to accommodate for distance, and poorly developed eyes, visual nerves, and brain. However, the normal neonate can see objects clearly within a range of 9 to 12 inches (22.9 to 30.5 cm), whether or not they are moving. Visual acuity at birth is 20/100 to 20/150, but it improves rapidly during infancy and toddlerhood. Newborns can distinguish colors as well as light from dark.

 CN: Health promotion and maintenance; CL: Apply

32. 4. The client is experiencing diastasis recti, a separation of the longitudinal muscles (recti) of the abdomen that is usually palpable on the 3rd postpartum day. An exercise involving raising the head and shoulders about 8 inches (20.3 cm) with the client lying on her back with knees bent and hands crossed over the abdomen is preferred. This exercise helps to pull the abdominal muscles together, and the client gradually works up to performing this exercise 50 times per day. However, until the diastasis has closed, the client should avoid exercises that rotate the trunk, twist the hips, or bend the trunk to one side, because further separation may occur. The condition does not need a surgical repair, and limited activity and bed rest are not necessary. Correct posture and adequate diet assist the body to return to its prepregnancy state more quickly but do not resolve the separation of abdominal muscles.

 CN: Reduction of risk potential; CL: Synthesize

33. 3. A uterine fundus located off to one side and above the level of the umbilicus is commonly the result of a full bladder. Although the client had voided, the client may be experiencing urinary retention with overflow. If anesthesia has been used for birth, the inability to void may be related to the

lingering effects of anesthesia; however, that is not the case here. **Healthcare providers (HCP)**  commonly write a one-time prescription for catheterization, after which, typically, enough edema has subsided to make it easier and less painful for the client to void and completely empty her bladder. Administering ibuprofen would have no effect on the uterine fundus. Waiting to reassess in 1 hour could be detrimental since the client's distended bladder is interfering with uterine involution, predisposing her to possible hemorrhage. Administering a bolus of fluid would be inappropriate because it would only add to the client's full bladder.

 CN: Reduction of risk potential; CL: Synthesize

34. 2. Stretch marks, or *striae gravidarum*, are caused by stretching of the tissues, particularly over the abdomen. After birth, the tissues atrophy, leaving silver scars. These skin pigmentations will not disappear completely. The striae gravidarum may reappear as pink streaks if the client becomes pregnant again. Special creams are not warranted because they are not helpful and may be expensive. Weight loss does not make the marks disappear. Striae gravidarum tend to run in families.

 CN: Health promotion and maintenance; CL: Synthesize

35. 1. The client with a third-degree laceration should be assessed for constipation because a third-degree laceration extends into a portion of the anal sphincter. Constipation, not diarrhea, is more likely because this condition is extremely painful, possibly causing the client to be reluctant to have a bowel movement. The laceration has been sutured and should not be bleeding at 48 hours postpartum. Rectal fistulas may develop at a later time, but not at 48 hours postpartum.

 CN: Reduction of risk potential; CL: Create

36. 4. For most clients, sexual intercourse can be resumed when the lochia has stopped flowing and episiotomy pain has ceased, usually about 3 weeks postpartum. Sexual intercourse may be painful until the episiotomy has healed. The client also needs instructions about the possibility that pregnancy may occur before the return of the client's menstrual flow. The postpartum check by the **HCP**  typically occurs 4 to 6 weeks after birth, and most women have already had intercourse by this time. Typically, new mothers are

exhausted and may not feel amorous or desirable for quite a while. In addition, the mother's physiologic responses may be diminished because of low hormonal levels, adjustments to the maternal role, and fatigue due to lack of rest and sleep.

CN: Health promotion and maintenance; CL: Synthesize

37. 1. The nurse needs to continue to monitor the client's vital signs.

During the first 24 hours postpartum, it is normal for the mother to have a slight temperature elevation because of dehydration. A temperature of 100.4°F (38°C) that persists after the first 24 hours may indicate an infection. Bradycardia during the first week postpartum is normal because of decreased blood volume, diuresis, and diaphoresis. The client's respiratory rate is within normal limits. Large clots are indicative of hemorrhage. However, the client's vital signs are within normal limits and her fundus is firm and midline.

Therefore, large clots and possible hemorrhage can be ruled out. The **HCP**  does not need to be notified at this time. An ice pack is not necessary because the client's temperature is within normal limits.

CN: Health promotion and maintenance; CL: Synthesize

38. 3. The client needs more teaching when she states, "I should lie on my back as much as possible to relieve the pain." Instead, the client should lie in the Sims position as much as possible to aid venous return to the rectal area and to reduce discomfort. Stool softeners can decrease pain with defecation, but clients should discuss their use with their provider before taking them. Analgesic sprays and witch hazel pads are helpful in reducing the discomfort of hemorrhoids. Drinking lots of water and eating roughage aid in bowel elimination, minimizing the risk of straining and subsequent hemorrhoidal development or enlargement.

CN: Basic care and comfort; CL: Evaluate

39. 2. On most postpartum units, clients on regular diets are allowed to eat whatever kinds of food they desire. Generally, foods from home are not discouraged. The nurse does not need to obtain the **HCP's**  permission. Although it is preferred, the foods do not necessarily have to be high in iron. In some cultures, there is a belief in the "hot-cold" theory of disease; certain foods (hot) are preferred during the postpartum period, and other foods (cold)

are avoided. Therefore, the nurse should allow the mother to bring her daughter “special foods from home.” Doing so demonstrates cultural sensitivity and aids in developing a trusting relationship.

CN: Basic care and comfort; CL: Synthesize

40. 1. Iron is best absorbed in an acid environment or with vitamin C. For maximum iron absorption, the client should take the medication with orange juice or a vitamin C supplement. Herbal tea has no effect on iron absorption. Milk decreases iron absorption. Grape juice is not acidic and therefore would have no effect on iron absorption.

CN: Pharmacological and parenteral therapies; CL: Synthesize

41. 4. It is believed that the process of attachment is structured so that the parents become attached to only one infant at a time. Therefore, the nurse should encourage the parents to relate to each twin individually, rather than as a unit, to enhance the attachment process. Mothers of twins are usually able to breast-feed successfully because the milk supply increases on demand. However, possible fatigue and exhaustion require that the mother rest whenever possible. It would be highly unlikely and unrealistic that each parent would be able to spend equal amounts of time with both twins. Other responsibilities, such as employment, may prevent this. The parents should try to engage assistance from family and friends, because caring for twins or other multiple births (e.g., triplets) can be exhausting for the family.

CN: Psychosocial integrity; CL: Synthesize

42. 3. At 12 hours postpartum, the fundus normally should be in the midline and at the level of the umbilicus. When the fundus is firm yet above the umbilicus, and deviated to the right rather than in the midline, the client’s bladder is most likely distended. The client should be encouraged to ambulate to the bathroom and attempt to void because a full bladder can prevent normal involution. A firm but deviated fundus above the level of the umbilicus is not a normal finding, and if voiding does not return it to midline, it should be reported to the **HCP** 📖. Oxytocin is used to treat uterine atony. This client’s fundus is firm, not boggy or soft, which would suggest atony. Gentle massage is not necessary because there is no evidence of atony or clots.

 CN: Reduction of risk potential; CL: Synthesize

43. 1,2,3,5,6. The nurse is responsible for providing discharge instructions that include signs and symptoms that need to be reported to the **healthcare provider (HCP)**  as well as resources and follow-up for home care if needed. Phone numbers and health practices to promote healing, such as the use of prenatal vitamins, are also essential pieces of information. Fertility can return in as little as 21 days, especially among women who are not breast-feeding. So it is important to discuss the client's contraception plan. Although the client's mother may be helpful, the client's statement that she will be fine because her mother is coming indicates that she is unaware or ignoring information about valuable information and resources.

 CN: Reduction of risk potential; CL: Evaluate

The Postpartal Client Who Breast-feeds

44. 4. Depot medroxyprogesterone acetate (DMPA) is an injectable progestin contraceptive that can reduce the initial production of breast milk. It is given to a breast-feeding woman when she returns for the 6-week postpartum checkup. By this time, the milk supply is well established and will remain at that level. DMPA is effective as a contraceptive for 90 days. DMPA can be given within 5 days of birth only if a mother is not breast-feeding.

 CN: Pharmacological and parenteral therapies; CL: Evaluate

45. 3. As much of the mother's nipple and areola as possible need to be in the infant's mouth in order to establish a latch that does not cause nipple cracks or fissures. Having the nipple and the areola deep in the infant's mouth decreases the stress on the end of the nipple, therefore decreasing pain, cracking, and fissures. Breast milk has been found to heal nipples when placed on the nipple at the completion of a feeding. The length of time the baby feeds on each nipple is not a factor as long as the nipple is correctly placed in the infant's mouth.

 CN: Health promotion and maintenance; CL: Evaluate

46. 1. New mothers usually begin to produce milk at about the 3rd day

postpartum and colostrum is produced until that time. For clients who have breast-fed another infant during pregnancy, having milk shortly after birth is not unusual. Diaphoresis and diuresis are considered normal during this time as the body excretes the additional fluids that are no longer needed after the pregnancy. Constipation may continue for several days as a result of progesterone remaining in the system, the consumption of iron, and trauma to the perineum.

CN: Physiological adaptation; CL: Analyze

47. 2. The major reasons for afterbirth pains are breast-feeding, high parity, overdistended uterus during pregnancy, and a uterus filled with blood clots. Physiologically, afterbirth pains are caused by intermittent contraction and relaxation of the uterus. These contractions are stronger in multigravidas in order to maintain a contracted uterus. The release of oxytocin when breast-feeding also stimulates uterine contractions. There are no data to suggest any of these clients has had an overdistended uterus or currently has clots within the uterus. The G3, P3 client who is breast-feeding has the highest parity of the clients listed, which—in addition to breast-feeding—places her most at risk for afterbirth pains. The G2, P2 postcesarean client may have cramping, but it should be less than the G3, P3 client. The G3, P3 client who is bottle-feeding would be at risk for afterbirth pains because she has given birth to several children, but her choice to bottle-feed reduces her risk of pain.

CN: Physiological adaptation; CL: Evaluate

48. 2. The client is exhibiting signs and symptoms of a breast infection (mastitis). The nurse should instruct her to contact her **HCP** 📖, who will likely prescribe a prescription for antibiotics. She should continue to breast-feed the infant from both breasts. Frequent breast-feeding is encouraged rather than discontinuing the process for anyone having a breast infection. Applying warm compresses may relieve pain. However, the underlying infection indicated by the elevated temperature indicates that additional treatment with antibiotics will be needed.

CN: Management of care; CL: Synthesize

49. 4. Breast-feeding consumes maternal calories and requires energy that increases the maternal basal metabolic rate and assists in lowering the

maternal blood glucose level. Insulin is not transferred to the infant through breast milk. Breast-feeding is recommended for diabetic mothers because it does lower blood glucose levels. The number of antibodies in breast milk is not altered by maternal diabetes.

CN: Physiological adaptation; CL: Evaluate

50. 1. Jaundice in a breast-feeding infant is common and is not pathological. Mothers should be taught to breast-feed as often as possible, at least every 2 to 3 hours and until the infant is satiated. Breast-fed babies rarely need to be supplemented with formula. Mothers should be encouraged to continue breast-feeding their infants due to the numerous benefits it provides. Infants should never be placed in direct sunlight.

CN: Health promotion and maintenance; CL: Evaluate

51. 1. If not contraindicated for moral, cultural, or religious reasons, a condom with spermicide is commonly recommended for contraception after birth until the client's 6-week postpartal examination. This method has no effect on the neonate who is breast-feeding. Oral contraceptives containing estrogen are not advised for women who are breast-feeding because the hormones decrease the production of breast milk. Women who are not breast-feeding may use oral contraceptive agents. The rhythm method is not effective because the client is unlikely to be able to determine when ovulation has occurred until her menstrual cycle returns. Although breast-feeding is not considered an effective form of contraception, breast-feeding usually delays the return of both ovulation and menstruation. The length of the delay varies with the duration of lactation and the frequency of breast-feeding. While abstinence is one form of birth control and safe while breast-feeding, it may not be acceptable to this couple who is asking about a method that will allow them to resume sexual relations.

CN: Health promotion and maintenance; CL: Synthesize

52. 4. Colostrum is a thin, watery, yellow fluid composed of protein, sugar, fat, water, minerals, vitamins, and maternal antibodies (e.g., immunoglobulin A). It is important for the neonate to receive colostrum for passive immunity. Colostrum is lower in fat and lactose than mature breast milk. Colostrum does not contain vitamin K. The neonate will produce

vitamin K once a feeding pattern is established. Colostrum may speed, rather than delay, the passage of meconium.

CN: Health promotion and maintenance; CL: Apply

53. 3. Various medications can be excreted in the breast milk and affect the nursing neonate. The client should avoid all nonprescribed medications (such as acetaminophen) unless approved by the **healthcare provider (HCP)**

. Medications typically do not affect the quality of the mother's breast milk. Medications usually do not interfere with or diminish the mother's motivation to breast-feed, nor do they interfere with the mother's letdown reflex.

CN: Health promotion and maintenance; CL: Apply

54. 3. Taking ibuprofen 200 mg orally immediately after breast-feeding helps minimize the neonate's exposure to the drug because drugs are most highly concentrated in the body soon after they are taken. Most mothers breast-feed on demand or every 2 to 3 hours, so the effects of the ibuprofen should be decreased by the next breast-feeding session. Taking the medication before going to bed is inappropriate because, although the mother may go to bed at a certain time, the neonate may wish to breast-feed soon after the mother goes to bed. If the mother takes the medication midway between feedings, then its peak action may occur midway between feedings. Breast milk is sufficient for the neonate's nutritional needs. Most breast-feeding mothers should not be encouraged to provide supplemental feedings to the infant because this may result in nipple confusion.

CN: Pharmacological and parenteral therapies; CL: Apply

55. 4. Breast-feeding stimulates oxytocin secretion, which causes the uterine muscles to contract. These contractions account for the discomfort associated with afterpains. Flatulence may occur after a cesarean birth. However, the mother typically would have abdominal distention and a bloating feeling, not a “cramp-like” feeling. Stretching of the tissues or healing may cause slight tenderness or itching, not cramping feelings of discomfort. Medications such as mild analgesics or stool softeners, commonly administered postpartum, typically do not cause cramping.

 CN: Health promotion and maintenance; CL: Apply

56. 2. For the breast-feeding client, drinking at least 8 to 10 glasses of fluid a day is recommended. Breast-feeding women need an increased intake of vitamin D for calcium absorption. A breast-feeding woman requires an extra 500 cal/day above the recommended nonpregnancy intake to produce quality breast milk. Breast-feeding women need adequate calcium for blood clotting and strong bones and teeth.

 CN: Basic care and comfort; CL: Evaluate

57. 1. Breast milk has a higher fat content than cow's milk. Thirty to fifty-five percent of the calories in breast milk are from fat. Breast milk contains less iron than cow's milk does. However, the iron absorption from breast milk is greater in the neonate than with cow's milk. Breast milk contains less sodium and calcium than does cow's milk.

 CN: Basic care and comfort; CL: Apply

58. 4. Lightly brushing the neonate's lips with the nipple causes the neonate to open the mouth and begin sucking. The neonate should be taught to open the mouth and grasp the nipple on his or her own. The neonate should not be forced to nurse.

 CN: Health promotion and maintenance; CL: Apply

59. 2. Several methods can be used to prevent nipple soreness. Placing as much of the areola as possible into the neonate's mouth is one method. This action prevents compression of the nipple between the neonate's gums, which can cause nipple soreness. Other methods include changing position with each feeding, avoiding breast engorgement, nursing more frequently, and feeding on demand. Plastic liners are not helpful because they prevent air circulation, thus promoting nipple soreness. Instead, air drying is recommended. Pulling the baby's mouth out smoothly after only 10 minutes may prevent the baby from getting the entire feeding and increases nipple soreness. Any breast milk remaining on the nipples should not be wiped off because the milk has healing properties.

 CN: Health promotion and maintenance; CL: Synthesize

60. 4. Breast-fed neonates do not swallow as much air as bottle-fed neonates, but they still need to be burped. Good times to burp the neonate are when the mother switches from one breast to the other and at the end of the breast-feeding session. Neonates do not eat more if they are burped frequently. Breast-feeding mothers are advised not to supplement the feedings with formula because this may cause nipple confusion and decrease milk production. If supplements are given, the baby still needs to be burped. Neonates who are fed every 3 hours still need to be burped.

CN: Health promotion and maintenance; CL: Evaluate

61. 3. While there is some variation in recommendations, stored breast milk can be safely kept in the refrigerator for 5 to 7 days or in a deep freeze at 0°F (−18°C) for 12 months. Breast milk should be stored in glass containers because immunoglobulin tends to stick to plastic bottles. Breast milk can remain without refrigeration or loss of nutrients for up to 8 to 10 hours. The containers should be labeled with date, time, and amount to prevent inadvertent administration of spoiled milk. Frozen breast milk should be thawed in the refrigerator for a few hours, placed under warm tap water, and then shaken.

CN: Health promotion and maintenance; CL: Evaluate

62. 4. Oxytocin stimulates the letdown reflex when milk is carried to the nipples. A lactating mother can experience the letdown reflex suddenly when she hears her baby cry or when she anticipates a feeding. Some mothers have reported feeling the letdown reflex just by thinking about the baby. Progesterone plays an important role in pregnancy, but levels drop after giving birth. This hormone if taken for contraception too soon after birth may decrease milk supply. Estrogen influences development of female secondary sex characteristics and controls menstruation. Prolactin stimulates milk production.

CN: Health promotion and maintenance; CL: Apply

63. 3. Expressing a little milk before nursing, massaging the breasts gently, or taking a warm shower before feeding also may help to improve milk flow. Although various measures such as ice, heat, and massage may be tried to relieve breast engorgement, prevention of breast engorgement by

frequent feedings is the method of choice. Applying ice to the nipples does not relieve breast engorgement. However, it may temporarily relieve the discomfort associated with breast engorgement. Using lanolin on the nipples does not relieve breast engorgement and is unnecessary. Use of lanolin may cause sensitivity and irritation. Having frequent breast-feeding sessions, rather than offering the neonate a small amount of formula, is the method of choice for preventing and relieving breast engorgement. In addition, offering the neonate small amounts of formula may result in nipple confusion.

CN: Health promotion and maintenance; CL: Apply

64. 1. The nurse should instruct the client that the baby is getting enough to eat when there are six to eight wet diapers by the 5th day of age. Other signs include good suckling sounds during feeding, dripping breast milk at the mouth, and quiet rest or sleep after the feeding. By the 4th day of age, the infant should have soft yellow stools, not transitional (greenish) stools. Falling asleep easily after feeding on the first day is not a good indicator because most infants are sleepy during the first 24 hours. Most infants regain their lost birth weight in 7 to 10 days after birth. An infant who has gained weight during the first well-baby checkup (usually at 2 weeks) is getting sufficient breast milk at feedings.

CN: Health promotion and maintenance; CL: Apply

65. 4. The client should wean the infant gradually, eliminating one feeding at a time. The baby can be weaned to a bottle (formula) anytime the mother desires; she does not have to breast-feed for 4 months. Most infants (and mothers) develop a “favorite feeding time,” so this feeding session should be eliminated last. The client may wish to begin weaning with daytime feedings when the infant is busy.

CN: Health promotion and maintenance; CL: Create

66. 1,3. The client is experiencing symptoms of engorgement. Cool compresses between feedings can help decrease swelling. Determining when the baby last fed is critical as frequent feedings can help relieve symptoms. The nurse must also assess how long baby feeds, if it has a correct latch, and if baby empties breast during feeds. Sitting on supportive devices is not necessary as the epitiostomy is healing. Cool sitz baths do not promote

circulation to the area; instead they cause vasoconstriction and decrease blood flow to the area, therefore prolonging healing and increasing discomfort. Swab for a culture and sensitivity is not warranted at this time. If edema and redness continue for more than two days then further assessment is required to rule out infection.

CN: Basic care and comfort; CL: Synthesize

67. 4. Neonates normally increase breast-feeding during periods of rapid growth (growth spurts). These can be expected at age 10 to 14 days, 5 to 6 weeks, 2.5 to 3 months, and 4.5 to 6 months. Each growth spurt is usually followed by a regular feeding pattern. Lack of adequate intake to meet maternal nutritional needs is not associated with the neonate's desire for more frequent breast-feeding sessions. However, an intake of adequate calories is necessary to produce quality breast milk. The mother's fears about weight gain and preventing the neonate from sucking long enough are not associated with the desire for more frequent breast-feeding sessions.

CN: Health promotion and maintenance; CL: Analyze

68. 2. Even if the nipples are sore and cracked, the mother should position the baby with the entire areola in the baby's mouth so that the nipple is not compressed between the baby's gums during feeding. The best method is to prevent cracked nipples before they occur. This can be done by feeding frequently and using proper positioning. Warm, moist tea bags can soothe cracked nipples because of tannic acid in the tea. Creams on the nipples should be avoided; wiping off any lanolin creams from the nipple before each feeding can cause further soreness. Feeding the baby less often for the next few days will cause engorgement (and possible neonatal weight loss), leading to additional problems. Soap use while in the shower should be avoided to prevent drying and removal of protective oils.

CN: Reduction of risk potential; CL: Synthesize

69. 2. Time for bonding with their newborns is a frequent concern for fathers of breast-fed babies. It is common for fathers to express concern about having less intimate contact time. These feelings are normal, but they do not go away in a few days. The father of the baby has to dedicate time to spend with the infant where he can talk to, hold, cuddle, and/or play with the infant.

These strategies provide the infant with the contact and stimulation to establish a close bond between them. Bonding occurs from the moment of birth and continues in various ways between mother, father, and infant. Infants recognize and respond to touch, light, and voice immediately after birth. Bonding between both parents is equally important, and one does not take priority over the other.

 CN: Psychosocial integrity; CL: Apply

70. 4. A soft seedy unformed stool is the norm for a 4-day-old infant. It may surprise the mother as it is a change from the meconium the infant had since birth. This stool is not diarrhea even though it has no form. There is no need for the infant to be seen for this. As long as the infant is breast-feeding, the stools will remain of this color and consistency. Brown and formed stool is common for an infant who is bottle-fed or after the breast-feeding infant has begun eating food.

 CN: Physiologic adaptation; CL: Apply

The Postpartal Client Who Bottle-feeds

71. 1. By 4 to 6 weeks postpartum, the fundus should be deep in the pelvis and the size of a nonpregnant uterus. Subinvolution, caused by infection or retained placental fragments, is a problem associated with a uterus that is larger than expected at this time. Normal expectations include a white, thick vaginal discharge, striae that are beginning to fade to silver, and breasts that are soft without evidence of milk production (in a bottle-feeding mother).

 CN: Physiological adaptation; CL: Analyze

72. 4. The use of a breast pump to remove milk is contraindicated in bottle-feeding mothers. Nipple and breast stimulation and emptying of the breasts produce milk, rather than eliminate milk production. The bottle-feeding client is discouraged from stimulating the breasts in any way. A sports bra that is well fitting provides support and decreases stimulation. (Binders are not suggested.) Having the water in a shower land on the shoulders of the mother rather than the breasts also decreases stimulation. Only water is necessary to clean nipples when breast or bottle-feeding.

 CN: Basic care and comfort; CL: Evaluate

73. 3. Gaining 1 oz (30 g) a day is normal for a neonate. Initial weight loss that exceeds 10% of birth weight is abnormal. Adding rice cereal to a bottle without a medical indication increases the risk of aspiration and may promote obesity. Doubling the birth weight is typical at 5 months.

 CN: Basic care and comfort; CL: Apply

74. 1. Initial regurgitation in the neonate during the first 12 to 24 hours may be caused by excessive mucus and gastric irritation from foreign substances in the stomach. After the first 24 hours, regurgitation is thought to be caused by the neonate's immature cardiac sphincter. It represents an overflow of stomach contents and is probably a result of feeding the neonate too fast or too much. A defect in the gastrointestinal system usually results in more severe symptoms. A small amount of regurgitation is normal, but vomiting or forceful fluid expulsion is not. Burping the infant often during a feeding can decrease the amount of air in the stomach from swallowing. However, burping too often can lead the neonate to become tired or fussy. Moving the infant usually does not result in regurgitation.

 CN: Health promotion and maintenance; CL: Apply

75. 1. The neonate should be placed in a supine position. Placing infants on their side or prone in a crib after a feeding is no longer recommended due to the increased risk of sudden infant death syndrome (SIDS). Although the mother may desire to hold the infant in her lap after feeding, this is not necessary for the neonate's digestion unless the infant has reflux.

 CN: Health promotion and maintenance; CL: Apply

76. 2. Pediatricians recommend that infants be given either breast milk or formula until at least 6 months of age because of the neonate's difficulty digesting solid foods. Giving solid foods too early can lead to food allergies. Because chewing movements do not begin until 7 to 9 months of age, foods requiring chewing should be delayed until this time.

 CN: Health promotion and maintenance; CL: Apply

77. 1. The client needs further instruction when she says burping should be

done after 15 minutes of formula feeding. The entire feeding should take only 15 to 20 minutes, and the neonate should be burped before the feeding is complete. During initial feedings, the burping should be done after each half-ounce of formula with the neonate in an upright position, patting the neonate gently on the back.

CN: Health promotion and maintenance; CL: Evaluate

78. 2. Most babies are developmentally ready to drink independently from a cup by the age of 8 to 10 months. If the child has not mastered drinking from a cup by this time, there may be a problem with motor development that requires further investigation.

CN: Health promotion and maintenance; CL: Apply

The Postpartal Client with a Cesarean Birth

79. 3. The client should have more active bowel sounds by this time postpartum. Ambulation will encourage passing flatus and begin peristaltic action in the gastrointestinal track. Medicating the client should be evaluated prior to ambulating, but it is probably too soon because the last dose was 3 hours ago and her pain assessment rating is fairly low. Pain medications should not have codeine as a component as it decreases peristaltic activity. Incentive spirometry or asking the client to turn, cough, and deep breathe is appropriate to encourage good oxygen exchange in the lungs prior to ambulation, and walking can be used concurrently with these interventions. Participating in infant care is another way to encourage the mother to move about, but the primary goal would be to have her walk on the unit, a more purposeful activity.

CN: Physiological adaptation; CL: Synthesize

80. 2. Carboprost is an oxytocic prostaglandin that causes uterine contraction in women who are bleeding heavily. Nausea, vomiting, diarrhea, and fever are common adverse effects of prostaglandin administration. Vertigo and confusion are not associated with this drug. Carboprost may not control all cases of hemorrhage, but it does not cause bleeding. Restlessness typically is a sign of shock, not a reaction to carboprost. If too large a dose is given, the client may experience headache and hypertension because

carboprost contracts smooth muscles.

CN: Pharmacological and parenteral therapies; CL: Evaluate

81. 4. Slightly red-tinged urine may indicate that the bladder was accidentally cut during the cesarean birth. The nurse should notify the **HCP**  as soon as possible about the urine color. Continuing to monitor the client's input and output should be done after the HCP is contacted. Palpating the fundus every 15 minutes is not necessary unless the client's fundus becomes soft or "boggy." Assessment of the Foley catheter is a normal part of the elimination assessment by the nurse, but displacement is not the cause of the red-tinged urine.

CN: Reduction of risk potential; CL: Synthesize

82. 1. VBAC can be attempted if the client has not had a classic uterine incision. This type of incision carries a danger of uterine rupture. A **healthcare provider (HCP)**  must be available, and a cesarean birth must be possible within 30 minutes. A history of rapid labor is not a criterion for VBAC. A low transverse incision is not a contraindication for VBAC. A classic (vertical) incision is a contraindication because the client has a greater possibility for uterine rupture. Estimated fetal weight greater than 4,000 g by itself is not a contraindication if the mother is not diabetic.

CN: Health promotion and maintenance; CL: Apply

83. 3. For maximum effectiveness, RhoGAM should be administered within 72 hours postpartum. Most Rh-negative clients also receive RhoGAM during the prenatal period at 28 weeks' gestation and then again after birth. The drug is given to Rh-negative mothers who have a negative Coombs test and give birth to Rh-positive neonates. If there is doubt about the fetus's blood type after pregnancy is terminated, the mother should receive the medication.

CN: Pharmacological and parenteral therapies; CL: Apply

84. 1. After a cesarean birth, most mothers have the greatest comfort when the neonate is positioned in the football hold with the mother in semi-Fowler's position, supporting the neonate's head in her hand and resting the neonate's body on pillows alongside her hip. This position prevents pressure

on the uterine incision yet allows the neonate easy access to the mother's breast. The scissors hold, where the mother places her hand well back on the breast to prevent touching the areola and interfering with the neonate's mouth placement, is used by the mother to hold the breast and support it during breast-feeding. The cross-cradle hold is done when the mother holds the neonate's head in the hand opposite from the breast on which the neonate will feed and the mother's arm supports the neonate's body across her lap. This position can be uncomfortable because of the pressure placed on the client's incision line. For the cradle hold, the mother cradles the infant alongside the arm at the breast on which the neonate will feed. This position also can be uncomfortable because of the pressure placed on the incision line.

CN: Basic care and comfort; CL: Synthesize

The Postpartal Client with Complications

85. 4. A client who is pale and shaking could be experiencing hypovolemic shock likely caused by blood loss. A primary cause of blood loss after the birth of an infant is uterine atony. Therefore, the priority assessments should be the fundus of the uterus for firmness and location. In addition, the amount of vaginal bleeding (lochia) should also be assessed. An immediate intervention for uterine atony is fundal massage that will help the uterus to contract and therefore stop additional bleeding. Assessing the client's level of consciousness does not require additional time and can be done by the nurse while the fundus and lochia are assessed. Obtaining vital signs, blood glucose, and temperature are important but either should be done after the fundus has been assessed and massaged or should be obtained by a second responder. Assessing for uterine infection and pain should be done after treatment for hypovolemic shock has been initiated.

CN: Reduction of risk potential; CL: Analyze

86. 2. Pain after childbirth is generally well managed with pain control medications; since they did not help this woman, further assessment is necessary. The first nursing action would be to assess the source of the pain; the woman may have sustained a laceration or a hematoma as a result of childbirth. Assessing the perineum may help the nurse to determine the source of the pain and may require follow-up by the **healthcare provider**

(HCP).  Subsequent nursing interventions may include pain medication, sitz bath, or education regarding the healing process.

 CN: Basic care and comfort; CL: Analyze

87. 3. A pain and swelling may be indicative of thrombophlebitis. Redness at the site and may be more reliable as an indicator of thrombophlebitis. The nurse should notify the HCP  immediately and ask the client to remain in bed to minimize the risk for pulmonary embolus, a serious consequence of thrombophlebitis should a clot dislodge. Placing an ice pack on the perineal area is inappropriate. However, ice to the perineum would be useful for episiotomy pain and swelling. The client does not need to be positioned in semi-Fowler's position but should remain on bed rest to prevent dislodgement of a potential clot.

 CN: Reduction of risk potential; CL: Synthesize

88. 4. Heparin therapy is prescribed to prevent further clot formation by inhibiting further thrombus and clot formation. Heparin, an anticoagulant, does not make blood clots thinner. An adverse effect of heparin therapy during the puerperium is increased lochia flow, so the nurse must be observant for symptoms of hemorrhage, such as heavy lochial flow. Heparin does not increase diaphoresis, which is normal for the postpartum client.

 CN: Pharmacological and parenteral therapies; CL: Evaluate

89. 2. A major complication of deep vein thrombosis is pulmonary embolism. Signs and symptoms, which may occur suddenly and require immediate treatment, include dyspnea, severe chest pain, apprehension, cough (possibly accompanied by hemoptysis), tachycardia, fever, hypotension, diaphoresis, pallor, shortness of breath, and friction rub. Pain in the calf is common with a diagnosis of deep vein thrombosis. Hypotension, not hypertension, would suggest a possible pulmonary embolism. It also could suggest possible hemorrhage secondary to intravenous heparin therapy. Bradycardia for the first 7 days in the postpartum period is normal.

 CN: Reduction of risk potential; CL: Synthesize

90. 3. A slow pulse (bradycardia) is normal for the first 7 days postpartum as the body begins to adjust to the decrease in blood volume and return to the

prepregnant state. Adverse effects of heparin therapy suggesting prolonged bleeding include hematuria, epistaxis, increased lochial flow, and bleeding gums. Typically, tachycardia, not bradycardia, would be associated with hemorrhage. Petechiae indicate bleeding under the skin or in subcutaneous tissue.

CN: Reduction of risk potential; CL: Evaluate

91. 3. Successful teaching is demonstrated when the client says, “I should use a soft toothbrush to brush my teeth.” Heparin therapy can cause the gums to bleed, so a soft toothbrush should be used to minimize this adverse effect. Use of aspirin and other nonsteroidal anti-inflammatory medications should be avoided because of the increased risk for possible hemorrhage. Protamine sulfate is the antidote for heparin therapy. Vitamin K is the antidote for warfarin excess. Alcohol can inhibit the metabolism of oral anticoagulants and should be avoided.

CN: Pharmacological and parenteral therapies; CL: Evaluate

92. 4. Frequent handwashing is the most important aspect of infection control. The nurse can emphasize, monitor, and ensure this strategy for all who come in contact with this client. The use of gloves is not needed for clients caring for their own infants. The best practice is to restrict visitation if the client has a respiratory illness. If visitation is necessary, it is better if the client with the known infection wears the mask. Individual client care equipment is not needed in this situation.

CN: Reduction of risk potential; CL: Evaluate

93. 1,4,5. Endometritis is an ascending infection where organisms from the lower reproductive tract contaminate the normally sterile uterine lining. When the amniotic membranes rupture, bacteria from the cervix, vagina, perineum, and bowel can ascend into the uterus and infect the lining. Manual removal of placenta, prolonged labors, and the use of fetal scalp electrodes all increase the risk of developing endometritis postpartum. The use of in-and-out catheters during labor is not a risk factor for developing endometritis. Epidural use for pain relief in labor is not a risk factor for developing endometritis postpartum.

CN: Reduction of risk potential; CL: Analyze

94. 1. Before administering ampicillin intravenously, the nurse must ask the client if she has any drug allergies, especially to penicillin. Antibiotic therapy can cause adverse effects, such as rash or even anaphylaxis. If the client is allergic to penicillin, the **healthcare provider (HCP)**  should be notified, and ampicillin should not be given. Checking the client's pulse rate or placing her in a side-lying position is not necessary. Assessing the amount of lochia by checking the perineal pad is important for all postpartum clients but is not necessary before antibiotic therapy.

CN: Pharmacological and parenteral therapies; CL: Apply

95. 3. The nurse should encourage the client to maintain Fowler's position, which promotes comfort and facilitates drainage. Endometritis can make the client feel extremely uncomfortable and fatigued, so ambulation during intravenous therapy is not as important at this time. The client does not need to discontinue breast-feeding, although she may become quite fatigued and need assistance in caring for the neonate. Typically, breast-feeding would be discontinued only if the mother lacks the necessary energy. The institution's policy regarding visitors is to be followed. However, visitors do not need to be restricted to prevent contamination because the client is not considered to be contagious. The nurse should maintain the client's need for privacy and rest and should respect the client's wishes related to visitors.

CN: Reduction of risk potential; CL: Synthesize

96. 2. The client diagnosed with cystitis needs to void every 2 to 4 hours while awake to keep her bladder empty. In addition, she should maintain adequate fluid intake; 3,000 mL/day is recommended. Intake of acidic fruit juices (e.g., cranberry, apricot) is recommended because of their association with reducing the risk for infection. The client should wear cotton underwear and avoid tight-fitting slacks. She does not need to wash with povidone-iodine after voiding. Plain warm water is sufficient to keep the perineal area clean.

CN: Basic care and comfort; CL: Create

97. 1. The client can continue to breast-feed as often as she desires. Continuation of breast-feeding is limited only by the client's discomfort or malaise. Antibiotics for treatment are chosen carefully so that they avoid

affecting the neonate through breast milk. Drugs such as sulfonamides, nitrofurantoin, and cephalosporins usually are not prescribed for breast-feeding mothers. Manual pumping of the breasts is not necessary.

CN: Health promotion and maintenance; CL: Apply

98. 1. Carboprost tromethamine may cause hypertension, not hypotension. More commonly carboprost tromethamine, a synthetic prostaglandin, causes nausea, vomiting, diarrhea, and fever. Gastrointestinal symptoms are so common that antiemetic and antidiarrheal medications are often given as a pretreatment or immediately following carboprost.

CN: Pharmacological and parenteral therapies; CL: Analyze

99. 1. The client is exhibiting signs of early postpartal hemorrhage, defined as blood loss greater than 500 mL in the first 24 hours postpartum. Rapid intravenous oxytocin infusion of 30 units in 500 mL of normal saline, oxygen therapy, and gentle fundal massage to contract the uterus are usually effective. If bleeding persists, the nurse should inspect the cervix and vagina for lacerations. Other pharmacologic interventions may be needed. Severe uncontrolled hemorrhage may require bimanual uterine compression, a dilation and curettage to remove any retained placental tissue, or a hysterectomy to prevent maternal death from hemorrhage. The client should be placed in the supine position to allow evaluation of the fundus. The side-lying position is not helpful in controlling postpartum hemorrhage. Vigorous fundal massage every 5 minutes is unnecessary. In addition, it can be very painful for the mother. Rather, gentle massage along with oxytocin administration is used to stimulate the uterus to contract. A hysterectomy is used to remove fibroid tumors. With massive hemorrhage, a hysterectomy (removal of the uterus) may be necessary to control the bleeding.

CN: Health promotion and maintenance; CL: Create

100. 4. The most likely cause of this client's uterine atony is overdistention of the uterus caused by the hydramnios. As a result, the stretched uterine musculature contracts less vigorously. Besides hydramnios, a large infant, bleeding from abruptio placentae or placenta previa, and rapid labor and birth can also contribute to uterine atony during the postpartum period. Trauma during labor and birth is not a likely cause. In addition, no

evidence of excessive trauma was described in the scenario. Moderate fundal massage helps to contract the uterus, not contribute to uterine atony. Although a lengthy or prolonged labor can contribute to uterine atony, this client had a cesarean birth for breech presentation. Therefore, it is unlikely that she had a long labor.

 CN: Physiological adaptation; CL: Apply

101. 4. The classic symptoms of endometritis are fever and foul-smelling lochia. Odorless, heavy bleeding is associated with retained placental fragments. Abdominal distention is associated with parametritis as the pelvic cellulitis advances and spreads, causing severe pain and distention. Nausea and vomiting are associated with parametritis, resulting from an abscess and advancing pelvic cellulitis.

 CN: Reduction of risk potential; CL: Analyze

102. 4. The most likely cause of delayed postpartum hemorrhage is retained placental fragments. The client may be scheduled for a dilatation and curettage to remove remaining placental fragments. Uterine atony, cervical lacerations, and vaginal lacerations are commonly associated with early, not late, postpartum hemorrhage.

 CN: Health promotion and maintenance; CL: Apply

103. 1. The client being treated for mastitis should continue to breast-feed often, or at least every 2 to 3 hours. Treatment also includes bed rest, increased fluid intake, local heat application, analgesics, and antibiotic therapy. Continually emptying the breasts decreases the risk of engorgement or breast abscess. The client should not discontinue breast-feeding unless she chooses to do so. The client may continue breast-feeding while receiving antibiotic therapy. Generally, the breast milk is not contaminated by the offending organism and is safe for the neonate.

 CN: Physiological adaptation; CL: Synthesize

104. 1. Down syndrome is a genetic abnormality that is caused by an extra chromosome that results in mental retardation. The degree of mental retardation is difficult to predict in a neonate, although most children born with Down syndrome have some degree of mental retardation. Various

methods can be used to determine whether a neonate has Down syndrome, which is commonly manifested by hypotonia, poor Moro reflex, flat facial profile, up-slanting palpebral fissures, epicanthal folds, and hyperflexible joints. Genetic studies can be indicative of this disorder. Mothers older than 35 years of age are at a higher risk for having a child with Down syndrome. However, chromosomal abnormalities can occur regardless of the mother's age.

CN: Reduction of risk potential; CL: Evaluate

105. 1. After birth, the client should make the decision about how much she would like to participate in the neonate's care. Seeing and caring for the neonate commonly facilitates the grief process. The nurse should be nonjudgmental and should allow the client any opportunity to see, hold, and care for the neonate. The **healthcare provider (HCP)**  does not need to be contacted about the client's desire to see the baby, which is a normal reaction. The social worker and the adoptive parents do not need to give the client permission to feed the baby.

CN: Health promotion and maintenance; CL: Synthesize

106. 4. The client needs further instruction when she says that she should begin feeding on the right (painful) breast to decrease the pain. Starting the feeding on the unaffected (left) breast can stimulate the milk ejection reflex in the right breast and thereby decrease the pain. Frequent nursing or pumping is recommended to empty the breast. For some mothers, mastitis is so painful that they choose to discontinue breast-feeding, so these mothers need a great deal of support. Applying heat to the infected area before starting to feed is appropriate because heat stimulates circulation and promotes comfort. Increasing fluid intake is advised to ensure adequate hydration. Antibiotics need to be taken until all medication has been used, usually 7 to 10 days to ensure eradication of the infection.

CN: Reduction of risk potential; CL: Evaluate

107. 3. The client is probably experiencing postpartum depression, and the **healthcare provider (HCP)**  should be contacted. Postpartum depression is usually treated with psychotherapy, social support groups, and antidepressant medications. Contributing factors include hormonal

fluctuations, a history of depression, and environmental factors (e.g., job loss). An estimated 50% to 70% of women experience some degree of postpartum “blues,” but these feelings of sadness disappear within 1 to 2 weeks after birth. However, the client is voicing more than just sadness. Telling her that she is overreacting is not helpful and may make her feel even less worthy. She is not exhibiting symptoms of a serious mental illness (loss of contact with reality) and does not need hospitalization.

CN: Health promotion and maintenance; CL: Synthesize

108. 3. Feelings of guilt combined with a lack of self-care (not eating or sleeping enough) can predispose a new mother to postpartum depression, especially one who has had previous episodes of depression. Sleep is essential to both the mother and baby, but sleeping through the night does not usually occur in the first few weeks after birth. While breast-feeding mothers do need good nutrition, eating as much as you want after birth may inhibit the return to a normal weight and could create depression in a new mother, especially a vulnerable one. Attempting to care for an infant with no help from others is likely to cause stress that could lead to depression, especially in an adolescent.

CN: Psychosocial integrity; CL: Evaluate

Managing Care, Quality, and Safety of Postpartal Clients

109. 2,3,1,4. The nurse should then clean the solution from the client, notify the **healthcare provider (HCP)**  of the incident, and ask for a prescription for medication if needed to counteract the povidone-iodine. The nurse will need to document the incident on the client’s **medical record**  as soon as the client has physically been taken care of. The nurse also will need to file an incident report.

CN: Management of care; CL: Synthesize

110. 4. The process for infant abduction in a hospital system focuses on utilizing all healthcare workers to observe for anyone who may possibly be concealing an infant in a large bag or under an oversized coat and is attempting to leave the building. Moving to the entrances and exits and checking each individual would be a responsibility of the doorman or security

staff within the hospital system. Going to the obstetrics unit to determine if they need help would not be advised as the doors to the unit will be locked and access will not be available. Calling the nursery to ask about a missing baby wastes time, and the nursery staff should not reveal such information.

CN: Safety and infection control; CL: Synthesize

111.

0500	3
0530	1
0600	4
0630	2

Drawing the bilirubin levels at 0600 must occur at a specific time. The admission assessment should be completed as soon after admission as possible; 0500 is available to complete this task. The IV should be started at 0630 and completed as close to change of shift as possible. The nurse should then draw the blood at 0530, right after the newborn assessment.

CN: Management of care; CL: Create

112. 4. While the greatest risk of postpartum hemorrhage is within the first hour following birth, a woman can develop an early postpartum hemorrhage anytime within the first 24 hours postbirth. As soon as the nurse notices an increased amount of lochia and clots, the fundus must be assessed for firmness and position. Normally, it should be firm, midline, and either just above or below the umbilicus. Massaging the fundus if it is not firm will assist with a uterine contraction to help decrease blood loss postpartum. Administering oxytocin would not be the first action for the nurse to take. Performing an in-and-out catheterization at this time is not appropriate. The nurse should assist the woman to the washroom to void on her own first. The nurse can measure the blood loss by measuring the perineal pad; however, this would be done after the nurse has first assessed the fundus.

CN: Management of care; CL: Synthesize

113. 1. Hemoglobin (hgb) values following birth remains close to that during pregnancy. This value would indicate low hgb value and requires

further follow-up by notifying **HCP**  and documentation. WBC of $18,000 \times 10^9/L$ is considered normal during postpartum period. This is normal value for hematocrit. 9 mmol/L for serum iron is within normal range. WBC is within normal range for postpartum period and will not require parenteral antibiotics. Vital signs can be assessed following contacting the HCP. Pain medication is not indicated at this time based on these lab values.

 CN: Management of care; CL: Synthesize

114. 1,5. Foul-smelling lochia and an elevated temperature greater than 100.8°F (38.2°C) are signs of a postpartum infection and should be reported to the **HCP** . Bilateral engorgement is not an unusual finding and typically responds to nursing interventions such as use of ice packs. Postpartum blues can cause the client to cry easily for up to 2 weeks after birth. Soaking a peripad every 3 to 4 hours is a normal amount of lochia for a postpartum client within a week of birth.

 CN: Management of care; CL: Synthesize

115. 1. Safety is the highest priority, and a nursing error has occurred. If the day nurse decides to tell the night nurse, the timing of the notification will be up to the nurse initiating the incident report. The nurse should confer with the charge nurse concerning the incident, but completion of the report is required. Waiting for several hours to initiate the report based on changes in client data and assessment is not an ethical or professional decision and should not be considered; again, safety is the highest priority.

 CN: Reduction of risk; CL: Analyze

116. 2,3,4,5. The use of recycling bins on the unit does not impact safety or contribute to the quality of care. The infant identification system is a safety practice. Nursing influences the type of system used and how monitoring and identification occur, which improves the quality of care. The sibling and family visitation policy can be an excellent project. Sibling policies regarding visitation can influence safety (safety of mother and infant by keeping children with colds/flu, infections away from the obstetrics unit). Nursing influences development of the policy utilized and implemented on a daily basis. Postpartum instructions represent an area where the skill level, quality, and quantity of instruction represent nursing contributions to care. The ability

for a family to remain together during a hospital stay is important to families. The quality of the obstetrical experience can be enhanced or determined to be negative by this particular policy, one that is often looked at by these committees.

 CN: Management of care; CL: Apply

117. 1,2,4,5. The safety of clients on an obstetrical unit does include prevention of infant abduction. Safe medication administration guidelines apply in obstetrics as well as all units in the hospital system. Adequate nourishment on the unit is essential for promotion of breast-feeding and for those clients who want to eat shortly after birth but is not a safety concern. Adequate restraints as used during procedures, such as circumcisions, are a safety concern. An infant always needs proper identification when admitted, discharged, and taken to or away from parents, and this is also a great safety issue.

 CN: Reduction of risk; CL: Apply

118. 1,2,3,4. Specific safety concerns on an obstetrical unit include a very specific “hand-off report” after birth and recovery has been completed and the couplet is transitioned to mother-baby care. In any invasive procedure including tubal ligations and circumcisions, preprocedure verification is a - standard procedure. Client education concerning the potential for infection in obstetrics is essential for any incision areas. Infant abduction is an ever-present concern for those working in a mother-baby unit. Car seat instructions for new parents involve the infant being in the back seat of a car facing backward—**not** in the front seat. Education for the family includes this important area.

 CN: Reduction of risk potential; CL: Evaluate

119. 2. The fundus descends at the rate of 1 to 2 cm/day and by 2 weeks is no longer a pelvic organ. The vital signs, breasts, heart, lungs, abdomen (with exception of fundus), lochia, perineum, and extremities are within normal limits.

 CN Reduction of risk potential; CL: Analyze

The Neonatal Client

- Neonatal Care
- Physical Assessment of the Neonatal Client
- The Preterm Neonate
- The Postterm Neonate
- The Neonate with Risk Factors
- Managing Care, Quality, and Safety of Neonatal Clients
- Answers, Rationales, and Test-Taking Strategies

Neonatal Care

1. A primiparous woman has recently given birth to a term infant. Priority teaching for the client includes information on:

- ☐ **1.** sudden infant death syndrome (SIDS).
- ☐ **2.** breast-feeding.
- ☐ **3.** infant bathing.
- ☐ **4.** infant sleep-wake cycles.

2. A newborn who is 20 hours old has a respiratory rate of 66, is grunting when exhaling, and has occasional nasal flaring. The newborn's temperature is 98°F (36.6°C); he is breathing room air and is pink with acrocyanosis. The mother had membranes that were ruptured 26 hours before birth. What nursing actions are **most** indicated?

- ☐ **1.** Continue recording vital signs, voiding, stooling, and eating patterns every 4 hours.
- ☐ **2.** Place a pulse oximeter, and contact the healthcare provider (HCP) for a prescription to draw blood cultures.

- ☐ 3. Arrange a transfer to the neonatal intensive care unit with diagnosis of possible sepsis.
- ☐ 4. Draw a complete blood count (CBC) with differential and feed the infant.

3. A neonate is born by cesarean section at 36 weeks' gestation. The temperature in the birthing room is 70°F (21.1°C). To prevent heat loss from convection, which action should the nurse take?

- ☐ 1. Dry the neonate quickly after birth.
- ☐ 2. Keep the neonate away from air conditioning vents.
- ☐ 3. Place the neonate away from outside windows.
- ☐ 4. Prewarm the bed.

4. The healthcare provider (HCP) prescribes ampicillin 100 mg/kg/dose for a newly admitted neonate. The neonate weighs 1,350 g. How many milligrams should the nurse administer? Record your answer using one decimal place.

mg.

5. A neonate born at 30 weeks' gestation and weighing 2,000 g is admitted to the neonatal intensive care unit. What nursing measure will decrease insensible water loss in a neonate?

- ☐ 1. bathing the baby as soon after birth as possible
- ☐ 2. use of eye patches with phototherapy
- ☐ 3. use of humidity in the incubator
- ☐ 4. use of a radiant warmer

6. A septic preterm neonate's IV was removed due to infiltration. The nurse prioritizes restarting the IV to help which complication?

- ☐ 1. fever
- ☐ 2. hyperkalemia
- ☐ 3. hypoglycemia
- ☐ 4. tachycardia

7. The nurse makes a home visit to a 3-day-old full-term neonate who weighed 3,912 g (8 lb, 10 oz) at birth. Today the neonate, who is being

bottle-fed, weighs 3,572 g (7 lb, 14 oz). Which instructions should the nurse give to the mother?

- ☐ 1. Continue feeding every 3 to 4 hours since the weight loss is normal.
- ☐ 2. Contact the healthcare provider (HCP).
- ☐ 3. Switch to a soy-based formula because the current one seems inadequate.
- ☐ 4. Change to a higher-calorie formula to prevent further weight loss.

8. Commercial formulas contain 20 calories per 30 mL. A 1-day-old infant was fed 45 mL at 0200, 0530, 0800, 1,100, 1,400, 1,630, 2,000, and 2,230. What is the total amount of calories the infant received today? Record your answer using one decimal place.
calories.

9. A healthy neonate was just born in stable condition. In addition to drying the infant, what is the preferred method to prevent heat loss?

- ☐ 1. placing the infant under a radiant warmer
- ☐ 2. wrapping the infant in warm blankets
- ☐ 3. applying a knit hat
- ☐ 4. placing the infant skin-to-skin on the mother

10. The nurse is preparing to administer a vitamin K injection to a male neonate shortly after birth. What statement by the mother indicates that she understands the purpose of the injection?

- ☐ 1. "My baby does not have the normal bacteria in his intestines to produce this vitamin."
- ☐ 2. "My baby is at a high risk for a problem involving his blood's ability to clot."
- ☐ 3. "The red blood cells my baby formed during pregnancy are destroying the vitamin K."
- ☐ 4. "My baby's liver is not able to produce enough of this vitamin so soon after birth."

11. The nurse is teaching the mother of a newborn to develop her baby's sensory system. To further improve the infant's most developed sense, the nurse should instruct the mother to:

- ☐ 1. speak in a high-pitched voice to get the newborn's attention.
- ☐ 2. place the newborn about 12 inches from maternal face for best sight.
- ☐ 3. stroke the newborn's cheek with her nipple to direct the baby's mouth to nipple.
- ☐ 4. give infant formula with a sweetened taste to stimulate feeding.

12. The nurse has completed discharge teaching with new parents who will be bottle-feeding their normal term newborn. Which statement by the parents reflects the need for more teaching?

- ☐ 1. "Our baby will require feedings through the night for several weeks or months after birth."
- ☐ 2. "The baby should burp during and after each feeding with no projective vomiting."
- ☐ 3. "Our baby should have one to three soft, formed stools a day."
- ☐ 4. "We should weigh our baby daily to make sure he is gaining weight."

13. The nurse knows the mother of a neonate has understood her car seat safety instructions when she comments:

- ☐ 1. "I did not realize that even children between 1 to 2 years old are safer in rear-facing car seats."
- ☐ 2. "I should put my car seat in the front so I can watch my baby when I drive."
- ☐ 3. "I plan to use the car seat I saved from my last baby 10 years ago."
- ☐ 4. "The front-facing car seats do a better job supporting the head and neck of my baby."

14. While making a home visit to a primiparous client and her 3-day-old son, the nurse observes the mother changing the baby's disposable diaper. Before putting the clean diaper on the neonate, the mother begins to apply baby powder to the neonate's buttocks. Which information about baby powder should the nurse relate to the mother?

- ☐ 1. It may cause pneumonia to develop.
- ☐ 2. It helps prevent diaper rash.
- ☐ 3. It keeps the diaper from adhering to the skin.
- ☐ 4. It can result in allergies later in life.

15. After teaching a new mother about the care of her neonate after circumcision with a Gomco clamp, which statement by the mother indicates to the nurse that the mother needs additional instructions?

- ☐ 1. "The petroleum gauze may fall off into the diaper."
- ☐ 2. "A few drops of blood oozing from the site is normal."
- ☐ 3. "I will leave the gauze in place for 24 hours."
- ☐ 4. "I will remove any yellowish crusting gently with water."

16. After completing discharge instructions for a primiparous client who is bottle-feeding her term neonate, the nurse determines that the mother understands the instructions when the mother says that she should contact the healthcare provider (HCP) if the neonate exhibits which sign or symptom?

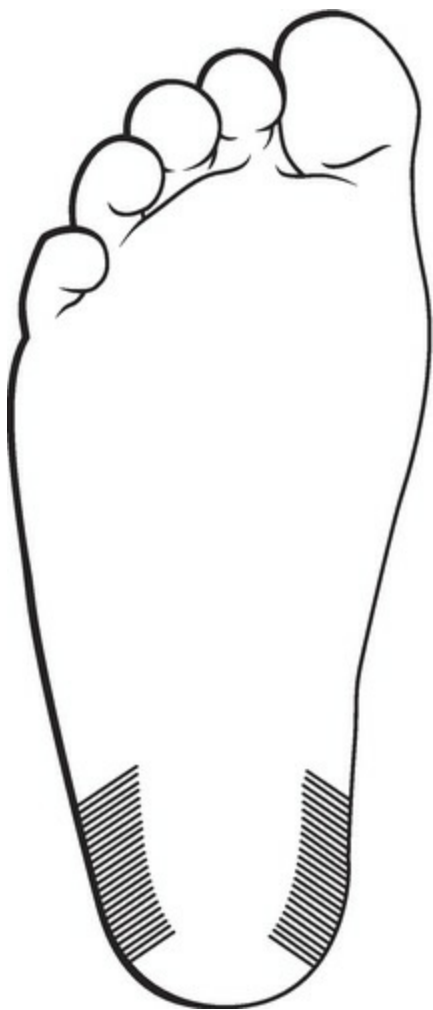

- ☐ 1. ability to fall asleep easily after each feeding
- ☐ 2. spitting up of a tablespoon of formula after feeding
- ☐ 3. passage of a liquid stool with a watery ring
- ☐ 4. production of one to two light brown stools daily

17. The nurse instructs a primiparous client about bottle-feeding her neonate. Which action demonstrates that the mother has understood the nurse's instructions?

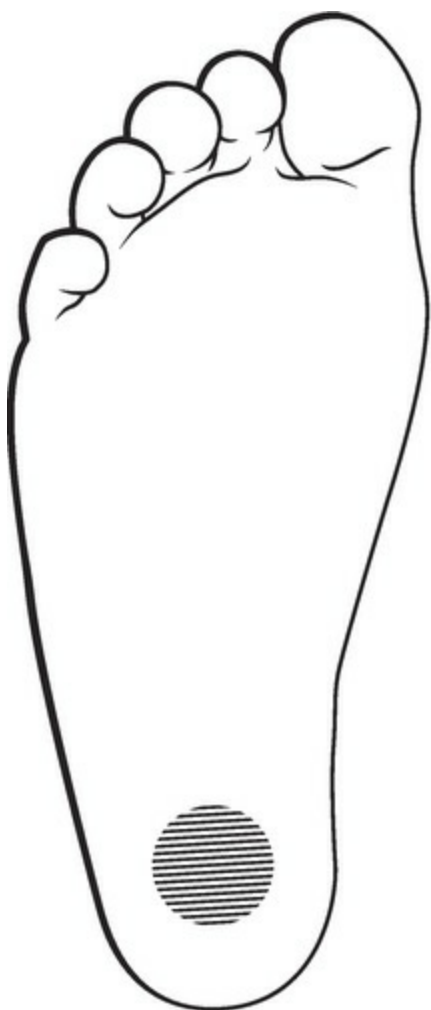

- ☐ 1. placing the neonate on his back after the feeding
- ☐ 2. bubbling the baby after 1 oz (30 mL) of formula
- ☐ 3. putting three-fourths of the bottle nipple into the baby's mouth
- ☐ 4. pointing the nipple toward the neonate's palate

18. The nurse is to draw a blood sample for glucose testing from a term neonate during the first hour after birth. The nurse should obtain the blood sample from the neonate's foot near which area?

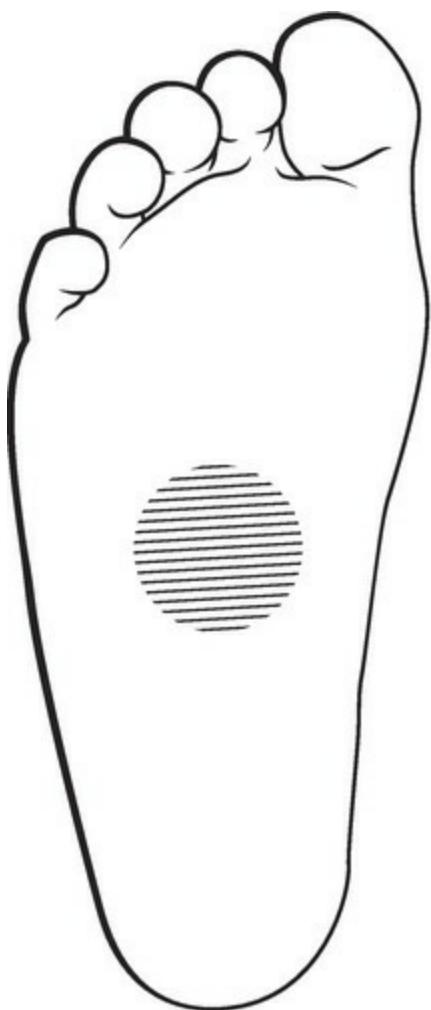

- ☐ 1.

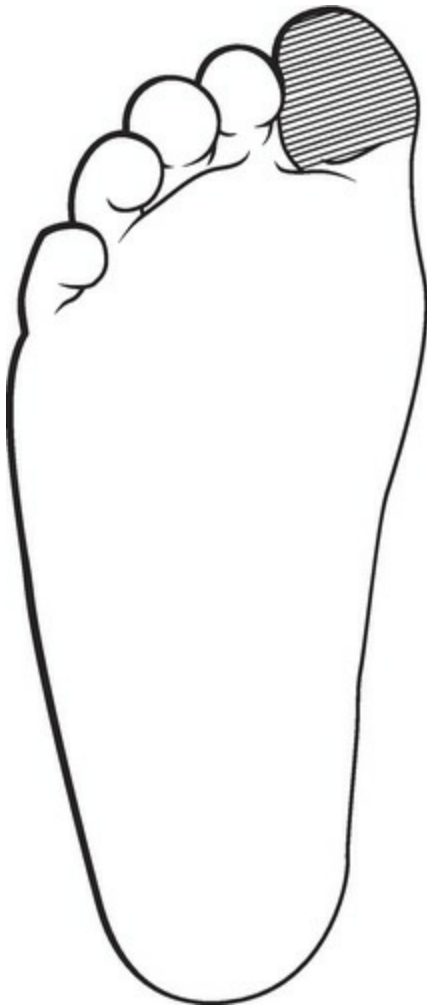

□ 2.

□ 3.

□ 4.

19. After circumcision with a Plastibell, the nurse should instruct the neonate's mother to cleanse the circumcision site using which agent?

- ☐ 1. antibacterial soap
- ☐ 2. warm water
- ☐ 3. povidone-iodine solution
- ☐ 4. diluted hydrogen peroxide

20. Based on the understanding of periods of reactivity, the nurse should encourage the mother of a term neonate to do which approximately 90 minutes after birth?

- ☐ 1. Feed the neonate.
- ☐ 2. Allow the neonate to sleep.
- ☐ 3. Get to know the neonate.
- ☐ 4. Change the neonate's diaper.

Physical Assessment of the Neonatal Client

21. The nurse is to assess a newborn for incurving of the trunk. Which illustration indicates the position in which the nurse should place the newborn?

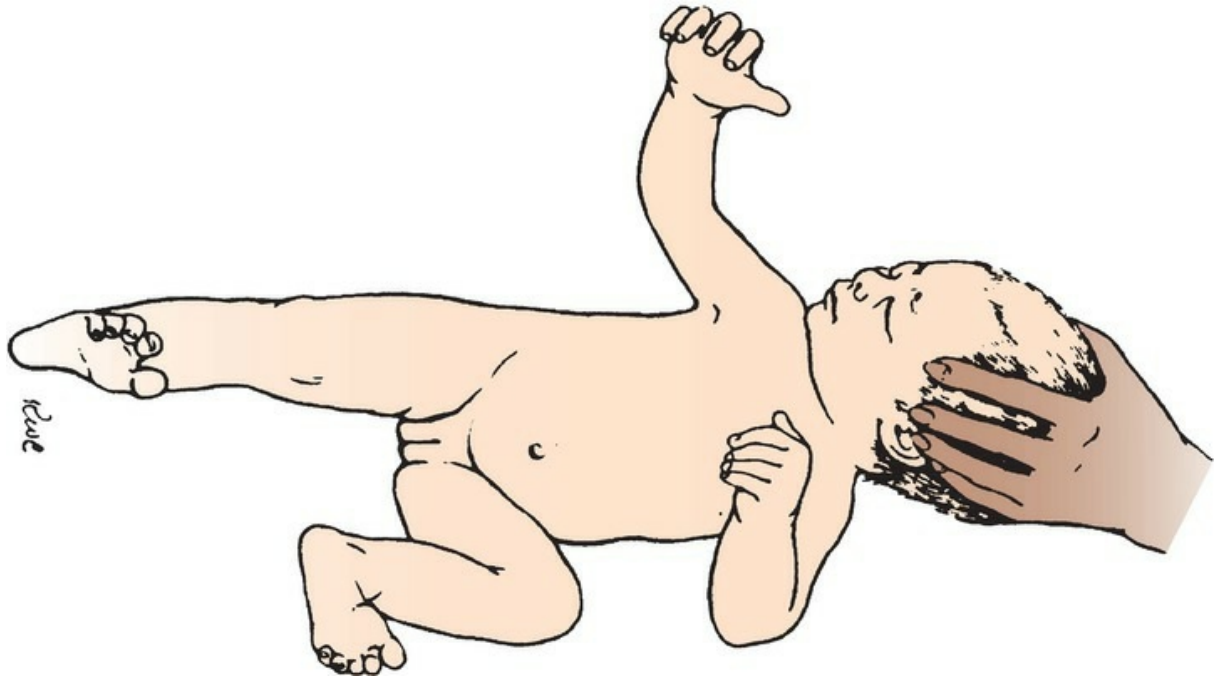

☐ 1.

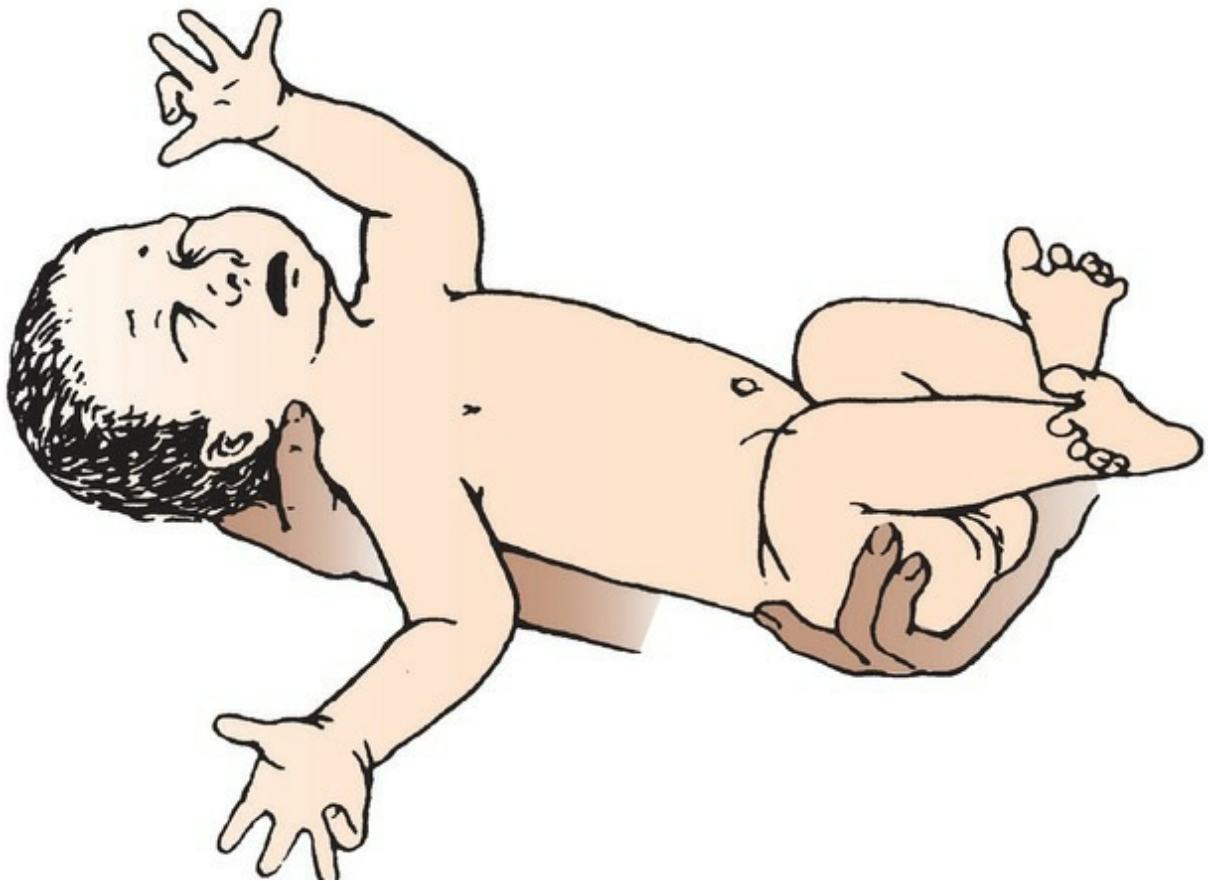

☐ 2.

□ 3.

□ 4.

22. A full-term neonate is admitted to the normal newborn nursery. When

lifting the baby out of the crib, the nurse notes the baby's arms move sideways with the palms up and the thumbs flexed. What should the nurse do **next**?

- ☐ 1. Call a code.
- ☐ 2. Identify this reflex as a normal finding.
- ☐ 3. Place the neonate on seizure precautions.
- ☐ 4. Start supplemental oxygen.

23. After the birth of a neonate, a quick assessment is completed. The neonate is found to be apneic. After quickly drying and positioning the neonate, what should the nurse do **next**?

- ☐ 1. Assign the first Apgar score.
- ☐ 2. Start positive pressure ventilation.
- ☐ 3. Administer oxygen.
- ☐ 4. Start cardiac compressions.

24. A 6-lb, 8-oz (2,948 g) neonate was born vaginally at 38 weeks' gestation. At 5 minutes of life, the neonate has the following signs: heart rate 110, intermittent grunting with respiratory rate of 70, flaccid tone, no response to stimulus, and overall pale white in color. The Apgar score is:

- ☐ 1. 2
- ☐ 2. 3
- ☐ 3. 4
- ☐ 4. 6

25. A neonate has a large amount of secretions. After vigorously suctioning the neonate, the nurse should assess for what possible result?

- ☐ 1. bradycardia
- ☐ 2. rapid eye movement
- ☐ 3. seizures
- ☐ 4. tachypnea

26. When reviewing the prenatal history for a newly born neonate, the nurse notes that the mother has neurofibromatosis. The nurse should further assess the neonate for:

- ☐ 1. acrocyanosis.

- ☐ 2. café au lait spots.
- ☐ 3. port-wine nevus.
- ☐ 4. strawberry hemangiomas.

27. A 24-hour-old, full-term neonate is showing signs of possible sepsis. The nurse is assisting the healthcare provider (HCP) with a lumbar puncture on this neonate. What should the nurse do to assist in this procedure? Select all that apply.

- ☐ 1. Administer the IV antibiotic.
- ☐ 2. Hold the neonate steady in the correct position.
- ☐ 3. Ensure a patent airway.
- ☐ 4. Maintain a sterile field.
- ☐ 5. Obtain a serum glucose level.

28. After vaginal birth of a term neonate, the nurse observes that the neonate has one artery and one vein in the umbilical cord. The nurse notifies the healthcare provider (HCP) based on the analysis that this may be indicative of which anomalies?

- ☐ 1. respiratory anomalies
- ☐ 2. musculoskeletal anomalies
- ☐ 3. cardiovascular anomalies
- ☐ 4. facial anomalies

29. While changing the neonate's diaper, the client asks the nurse about some red-tinged drainage from the neonate's vagina. Which response would be **most** appropriate?

- ☐ 1. "It is of no concern because it is such a small amount."
- ☐ 2. "The cause is usually related to swallowing blood during the birth."
- ☐ 3. "Sometimes baby girls have this from hormones received from the mother."
- ☐ 4. "This vaginal spotting is caused by hemorrhagic disease of the newborn."

30. Which finding would the nurse expect as common for a multiparous client giving birth to a viable neonate at 41 weeks' gestation with the aid of a vacuum extractor?

- ☐ 1. caput succedaneum
- ☐ 2. cephalohematoma
- ☐ 3. maternal lacerations
- ☐ 4. neonatal intracranial hemorrhage

31. After explaining to a primiparous client about the causes of her neonate's cranial molding, which statement by the mother indicates the need for further instruction?

- ☐ 1. "The molding was caused by an overlapping of the baby's cranial bones during my labor."
- ☐ 2. "The amount of molding is related to the amount and length of pressure on the head."
- ☐ 3. "The molding will usually disappear in a couple of days."
- ☐ 4. "Brain damage may occur if the molding does not resolve quickly."

32. Which observation is expected when the nurse is assessing the gestational age of a neonate born at term?

- ☐ 1. ear lying flat against the head
- ☐ 2. absence of rugae in the scrotum
- ☐ 3. sole creases covering the entire foot
- ☐ 4. square window sign angle of 90 degrees

33. While performing a complete assessment of a term neonate, which finding would alert the nurse to notify the healthcare provider (HCP)?

- ☐ 1. red reflex in the eyes
- ☐ 2. expiratory grunt
- ☐ 3. respiratory rate of 45 breaths/min
- ☐ 4. prominent xiphoid process

34. After instructing a mother about normal reflexes of term neonates, the nurse determines that the mother understands the instructions when she describes the tonic neck reflex as occurring when the neonate displays which behavior?

- ☐ 1. steps briskly when held upright near a firm, hard surface
- ☐ 2. pulls both arms and does not move the chin beyond the point of the elbows

- ☐ 3. turns head to the left, extends left extremities, and flexes right extremities
- ☐ 4. extends and abducts the arms and legs with the toes fanning open

35. A primiparous client expresses concern, asking the nurse why her neonate's eyes are crossed. Which information would the nurse include when teaching the mother about neonatal strabismus?

- ☐ 1. The neonate's eyes are unable to focus on light at this time.
- ☐ 2. Neonates commonly lack eye muscle coordination.
- ☐ 3. Congenital cataracts may be present.
- ☐ 4. The neonate is able to fixate on distant objects immediately.

36. While performing a physical assessment on a term neonate shortly after birth, which finding would cause the nurse to notify the healthcare provider (HCP)?

- ☐ 1. deep creases across the soles of the feet
- ☐ 2. frequent sneezing during the assessment
- ☐ 3. single crease on each of the palms
- ☐ 4. absence of lanugo on the skin

37. Metabolic screening of an infant revealed a high phenylketonuria (PKU) level. Which statement by the infant's mother indicates understanding of the disease and its management? Select all that apply.

- ☐ 1. "My baby cannot have milk-based formulas."
- ☐ 2. "My baby will grow out of this by the age of 2."
- ☐ 3. "This is a hereditary disease, so any future children will have it, too."
- ☐ 4. "My baby will eventually become mentally challenged because of this disease."
- ☐ 5. "We have to follow a strict low-phenylalanine diet."
- ☐ 6. "A dietitian can help me plan a diet that keeps a safe phenylalanine level but lets my baby grow."

38. Assessment of a term neonate at 2 hours after birth reveals a heart rate of less than 100 bpm, periods of apnea approximately 25 to 30 seconds in length, and mild cyanosis around the mouth. The nurse notifies the healthcare provider (HCP) based on the interpretation that these findings may lead to

which condition?

- ☐ 1. respiratory arrest
- ☐ 2. bronchial pneumonia
- ☐ 3. intraventricular hemorrhage
- ☐ 4. epiglottitis

39. A new mother asks, “When will the soft spot near the front of my baby’s head close?” The nurse should tell the mother the soft spot will close in about:

- ☐ 1. 2 to 3 months
- ☐ 2. 6 to 8 months
- ☐ 3. 9 to 10 months
- ☐ 4. 12 to 18 months

40. Which assessment finding in a term neonate would cause the nurse to notify the healthcare provider (HCP)?

- ☐ 1. absence of tears
- ☐ 2. unequally sized corneas
- ☐ 3. pupillary constriction to bright light
- ☐ 4. red circle on pupils seen with a penlight

41. At 24 hours of age, assessment of the neonate reveals the following: eyes closed, skin pink, no sign of eye movements, heart rate of 120 bpm, and respiratory rate of 35 breaths/min. What is this neonate **most** likely experiencing?

- ☐ 1. drug withdrawal
- ☐ 2. first period of reactivity
- ☐ 3. a state of deep sleep
- ☐ 4. respiratory distress

42. While assessing a male neonate whose mother desires him to be circumcised, the nurse observes that the neonate’s urinary meatus appears to be located on the ventral surface of the penis. The healthcare provider (HCP) is notified because the nurse suspects which complication?

- ☐ 1. phimosis

- ☐ 2. hydrocele
- ☐ 3. epispadias
- ☐ 4. hypospadias

The Preterm Neonate

43. The nurse is discussing kangaroo care with the parents of a premature neonate. The nurse should tell the parents that the advantages of kangaroo care include which benefits? Select all that apply.

- ☐ 1. enhanced bonding
- ☐ 2. increased IQ
- ☐ 3. improved physiologic stability
- ☐ 4. decreased length of stay in the neonatal intensive care unit
- ☐ 5. improved breast-feeding

44. After a vaginal birth, a preterm neonate is to receive oxygen via mask. While administering the oxygen, the nurse would place the neonate in which position?

- ☐ 1. left side, with the neck slightly flexed
- ☐ 2. back, with the head turned to the left side
- ☐ 3. abdomen, with the head down
- ☐ 4. back, with the neck slightly extended

45. Which action should the nurse take when performing external chest compressions on a neonate born at 28 weeks' gestation?

- ☐ 1. Maintain a compression-to-ventilation ratio of 3:1.
- ☐ 2. Compress the sternum with the palm of the hand.
- ☐ 3. Compress the chest 70 to 80 times/min.
- ☐ 4. Displace the chest wall half the depth of the anterior-posterior diameter of the chest.

46. A preterm neonate who has been stabilized is placed in a radiant warmer and is receiving oxygen via an oxygen hood. Which action should the nurse take while administering oxygen in this manner?

- ☐ 1. Humidify the air being delivered.

- ☐ 2. Cover the neonate's scalp with a warm cap.
- ☐ 3. Record the neonate's temperature every 3 to 4 minutes.
- ☐ 4. Assess the neonate's blood glucose level.

47. Two hours ago, a neonate at 38 weeks' gestation and weighing 3,175 g (7 lb) was born to a primiparous client who tested positive for beta-hemolytic Streptococcus. Which finding would alert the nurse to notify the healthcare provider (HCP)?

- ☐ 1. alkalosis
- ☐ 2. increased muscle tone
- ☐ 3. temperature instability
- ☐ 4. positive Babinski's reflex

48. Assessment of a 2-day-old neonate born at 34 weeks' gestation reveals absent apical pulse left of the midclavicular line, cyanosis, grunting, and diminished breath sounds. After beginning oxygen, the **priority** intervention is to:

- ☐ 1. obtain a prescription for a stat chest x-ray.
- ☐ 2. reposition the neonate and then assess if the grunting and cyanosis resolve.
- ☐ 3. obtain a prescription for an echocardiogram.
- ☐ 4. obtain a complete blood count to determine infection.

49. Twenty-four hours after cesarean birth, a neonate at 30 weeks' gestation is diagnosed with respiratory distress syndrome (RDS). When explaining to the parents about the cause of this syndrome, the nurse should include a discussion about an alteration in the body's secretion of which substance?

- ☐ 1. somatotropin
- ☐ 2. surfactant
- ☐ 3. testosterone
- ☐ 4. progesterone

50. A viable male neonate born to a 28-year-old multiparous client by cesarean section because of placenta previa is diagnosed with respiratory distress syndrome (RDS). Which factor would the nurse explain as the factor

placing the neonate at the **greatest** risk for this syndrome?

- ☐ 1. mother's development of placenta previa
- ☐ 2. neonate born preterm
- ☐ 3. mother receiving analgesia 4 hours before birth
- ☐ 4. neonate with sluggish respiratory efforts after birth

51. While the nurse is caring for a neonate at 32 weeks' gestation in an isolette with continuous oxygen administration, the neonate's mother asks why the neonate's oxygen is humidified. The nurse should tell the mother:

- ☐ 1. "The humidity promotes expansion of the neonate's immature lungs."
- ☐ 2. "The humidity helps to prevent viral or bacterial pneumonia."
- ☐ 3. "Oxygen is drying to the mucous membranes unless it is humidified."
- ☐ 4. "Circulation to the baby's heart is improved with humidified oxygen."

52. A preterm neonate admitted to the neonatal intensive care unit at about 30 weeks' gestation is placed in an oxygenated isolette. The neonate's mother tells the nurse that she was planning to breast-feed the neonate. Which instructions about breast-feeding would be **most** appropriate?

- ☐ 1. Breast-feeding is not recommended because the neonate needs increased fat in the diet.
- ☐ 2. Once the neonate no longer needs oxygen and continuous monitoring, breast-feeding can be done.
- ☐ 3. Breast-feeding is contraindicated because the neonate needs a high-calorie formula every 2 hours.
- ☐ 4. Gavage feedings using breast milk can be given until the neonate can coordinate sucking and swallowing.

53. What is the best reason for assessing a neonate weighing 1,500 g at 32 weeks' gestation for retinopathy of prematurity (ROP)?

- ☐ 1. The neonate is at risk because of multiple factors.
- ☐ 2. Oxygen is being administered at a level of 21%.
- ☐ 3. The neonate was alkalotic immediately after birth.
- ☐ 4. Phototherapy is likely to be prescribed by the healthcare provider (HCP).

54. Which subject should the nurse include when teaching the mother of a

neonate diagnosed with retinopathy of prematurity (ROP) about possible treatment for complications?

- ☐ 1. laser therapy
- ☐ 2. anti-inflammatory eye drops
- ☐ 3. frequent testing for glaucoma
- ☐ 4. corneal transplants

55. Three days after admission of a neonate born at 30 weeks' gestation, the neonatologist plans to assess the neonate for intraventricular hemorrhage (IVH). The nurse should plan to assist the neonatologist by preparing the neonate for which test?

- ☐ 1. cranial ultrasonography
- ☐ 2. arterial blood specimen collection
- ☐ 3. radiographs of the skull
- ☐ 4. complete blood count specimen collection

56. Which finding would the nurse **most** expect to find in a neonate born at 28 weeks' gestation who is diagnosed with intraventricular hemorrhage (IVH)?

- ☐ 1. increased muscle tone
- ☐ 2. hyperbilirubinemia
- ☐ 3. bulging fontanelles
- ☐ 4. hyperactivity

57. An infant born premature at 34 weeks is receiving gavage feedings. The client holding her infant asks why the nurse places a pacifier in the infant's mouth during these feedings. The nurse replies that the pacifier helps in what ways? Select all that apply.

- ☐ 1. teaches the infant to coordinate the swallow
- ☐ 2. provides oral stimulation
- ☐ 3. keeps oral mucous membranes moist while the tube is in place
- ☐ 4. reminds the infant how to suck
- ☐ 5. stimulates secretions that help gastric emptying

58. While caring for a neonate born at 32 weeks' gestation, which finding would **most** suggest the infant is developing necrotizing enterocolitis (NEC)?

- ☐ 1. the presence of 1 mL of gastric residual before a gavage feeding
- ☐ 2. jaundice appearing on the face and chest
- ☐ 3. an increase in bowel peristalsis
- ☐ 4. abdominal distention

59. Which statement by the mother of a neonate diagnosed with bronchopulmonary dysplasia (BPD) indicates effective teaching?

- ☐ 1. "BPD is an acute disease that can be treated with antibiotics."
- ☐ 2. "My baby may require long-term respiratory support."
- ☐ 3. "Bronchodilators can cure my baby's condition."
- ☐ 4. "My baby may have seizures later on in life because of this condition."

60. A preterm infant born 2 hours ago at 34 weeks' gestation is experiencing rapid respirations, grunting, no breath sounds on one side, and a shift in location of heart sounds. The nurse should prepare to assist with which procedure?

- ☐ 1. placement of the neonate on a ventilator
- ☐ 2. administration of bronchodilators through the nares
- ☐ 3. suctioning of the neonate's nares with wall suction
- ☐ 4. insertion of a chest tube into the neonate

61. Which finding would lead the nurse to suspect that a neonate born at 34 weeks' gestation receiving intravenous fluids has developed overhydration?

- ☐ 1. hypernatremia
- ☐ 2. polycythemia
- ☐ 3. hypoproteinemia
- ☐ 4. increased urine specific gravity

62. 62. A newborn weighing 6½ lb (2,950 g) is to be given naloxone due to respiratory depression as a result of a narcotic given to the mother shortly before birth. The drug is to be given 0.01 mg/kg into the umbilical vein. The vial is marked 0.4 mg/mL. How many milligrams would the newborn receive? Record your answer using two decimal places.

- ☐ _____ mg.

The Postterm Neonate

63. A neonate born by cesarean at 42 weeks' gestation, weighing 4.1 kg (9 lb), with Apgar scores of 8 at 1 minute and 9 at 5 minutes after birth, develops an increased respiratory rate and tremors of the hands and feet 2 hours postpartum. What is the **priority** problem for this neonate?

- ☐ 1. ineffective airway clearance
- ☐ 2. hyperthermia
- ☐ 3. decreased cardiac output
- ☐ 4. hypoglycemia

64. At a home visit, the nurse assesses a neonate born vaginally at 41 weeks' gestation 5 days ago. Which of these findings warrants further assessment?

- ☐ 1. Frequent hiccups
- ☐ 2. Loose, watery stool in diaper
- ☐ 3. Pink papular vesicles on the face
- ☐ 4. Dry, peeling skin

65. When performing an initial assessment of a postterm male neonate weighing 4,000 g (8 lb, 13 oz) who was admitted to the observation nursery after a vaginal birth with low forceps, the nurse detects Ortolani's sign. Which action should the nurse take **next**?

- ☐ 1. Determine the length of the mother's labor.
- ☐ 2. Notify the healthcare provider (HCP) immediately.
- ☐ 3. Keep the neonate under the radiant warmer for 2 hours.
- ☐ 4. Obtain a blood sample to check for hypoglycemia.

66. A neonate is admitted to the neonatal intensive care unit for observation with a diagnosis of probable meconium aspiration syndrome (MAS). The neonate weighs 10 lb, 4 oz (4,650 g) and is at 41 weeks' gestation. What would be the **priority** problem for this neonate?

- ☐ 1. impaired skin integrity
- ☐ 2. hyperglycemia
- ☐ 3. risk for impaired parent-infant-child attachment

- ☐ 4. impaired gas exchange

67. The neonate in the nurse's care has a pneumothorax. The nurse knows the signs of early decompensation and to observe carefully for changes in which assessments? Select all that apply.

- ☐ 1. blood pressure
- ☐ 2. temperature
- ☐ 3. urinary output
- ☐ 4. color
- ☐ 5. heart rate

The Neonate with Risk Factors

68. A nurse is attempting to resuscitate a neonate. Thirty seconds of chest compressions have been completed. The neonate's heart rate remains less than 60 bpm. Epinephrine is given. What is the expected outcome for a neonate who has received epinephrine during resuscitation?

- ☐ 1. increased urine output
- ☐ 2. a normal heart rate
- ☐ 3. pain relief
- ☐ 4. sedation

69. A mother is visiting her neonate in the neonatal intensive care unit. Her baby is fussy, and the mother wants to know what to do. In order to quiet a sick neonate, what can the nurse teach the mother to do?

- ☐ 1. Bring in toys for distraction.
- ☐ 2. Place a musical mobile over the crib.
- ☐ 3. Stroke the neonate's back.
- ☐ 4. Use constant, gentle touch.

70. A neonate born at 40 weeks' gestation admitted to the nursery is found to be hypoglycemic. At 4 hours of age, the neonate appears pale and his pulse oximeter is reading 75% on room air. The nurse should:

- ☐ 1. increase the IV rate.
- ☐ 2. provide supplemental oxygen.
- ☐ 3. record the finding on the medical record and repeat the reading in 30

minutes.

- ☐ 4. wrap the neonate to increase body temperature.

71. A neonate with heart failure is being discharged home. In teaching the parents about the neonate's nutritional needs, the nurse should explain that:

- ☐ 1. fluids must be restricted.
- ☐ 2. decreased activity level should reduce the need for additional calories.
- ☐ 3. the formula should be low in sodium.
- ☐ 4. the neonate may need a more calorie-dense formula.

72. During an assessment of a neonate born at 33 weeks' gestation, a nurse finds and reports a heart murmur. An echocardiogram reveals patent ductus arteriosus, for which the neonate received indomethacin. An expected outcome after the administration of indomethacin to a neonate with patent ductus arteriosus is:

- ☐ 1. closure of a patent ductus arteriosus.
- ☐ 2. decreased bleeding time.
- ☐ 3. increased gastrointestinal function.
- ☐ 4. increased renal output.

73. A nurse is reviewing a client's maternal prenatal record and notes that the mother used narcotics during her pregnancy. A primary nursing intervention when caring for a drug-exposed neonate is to:

- ☐ 1. assess vital signs including blood pressure every hour.
- ☐ 2. minimize environmental stimuli.
- ☐ 3. place the infant in a well-lighted area.
- ☐ 4. increase eye contact with caregiver.

74. The nurse is receiving over the telephone a laboratory results report of a neonate's blood glucose level. The nurse should:

- ☐ 1. write down the results, read back the results to the caller from the laboratory, and receive confirmation from the caller that the nurse understands the results.
- ☐ 2. repeat the results to the caller from the laboratory, write the results on scrap paper first, and then transfer the results to the medical record.
- ☐ 3. indicate to the caller that the nurse cannot receive verbal results from

laboratory tests for neonates, and ask the laboratory to bring the written results to the nursery.

☐ 4. request that the laboratory send the results by e-mail to transfer to the client's medical record.

75. A multiparous client who has a neonate diagnosed with hemolytic disease of the newborn asks the nurse why the neonate has developed this problem. Which response by the nurse would be **most** appropriate?

- ☐ 1. "You are Rh positive, and the baby is Rh negative."
- ☐ 2. "You and the baby are both Rh negative."
- ☐ 3. "You are Rh negative, and the baby is Rh positive."
- ☐ 4. "The baby and you are both Rh positive."

76. After teaching the multiparous mother about hemolytic disease of the newborn and Rh sensitization, the nurse determines that the client understands why she was not sensitized during her other pregnancy when she makes which statement?

- ☐ 1. "My other baby had a different father."
- ☐ 2. "Like most women, I have immunity against the Rh factor."
- ☐ 3. "Antibodies are not usually formed until after exposure to an antigen."
- ☐ 4. "My blood could not neutralize antibodies formed from my first pregnancy."

77. After teaching a multiparous client about the effects of hemolysis due to Rh sensitization on the neonate at birth, the nurse determines that the client needs further instruction when the mother reports that the neonate may have which complication?

- ☐ 1. cardiac decompensation
- ☐ 2. polycythemia
- ☐ 3. anemia
- ☐ 4. splenic enlargement

78. After birth, a direct Coombs test is performed on the umbilical cord blood of a neonate with Rh-positive blood born to a mother with Rh-negative blood. The nurse explains to the client that this test is done to detect which information?

- ☐ 1. degree of anemia in the neonate
- ☐ 2. initial bilirubin level
- ☐ 3. antibodies coating the neonate's red blood cells
- ☐ 4. antigens coating the neonate's red blood cells

79. The nurse recognizes that teaching about the need for an exchange transfusion in a neonate with erythroblastosis fetalis has been effective if the parents describe the purpose of the transfusion is:

- ☐ 1. to replenish the neonate's leukocytes.
- ☐ 2. to restore the fluid and electrolyte balance.
- ☐ 3. to correct the neonate's anemia.
- ☐ 4. to replace Rh-negative blood with Rh-positive blood.

80. The nurse explains to the mother of a neonate diagnosed with erythroblastosis fetalis that the exchange transfusion is necessary to prevent damage primarily to which organ in the neonate?

- ☐ 1. kidneys
- ☐ 2. brain
- ☐ 3. lungs
- ☐ 4. liver

81. The nurse determines that a newborn is experiencing hypoglycemia based on which findings? Select all that apply.

- ☐ 1. a blood glucose reading of less than 30 mg/dL (1.7 mmol/L) at 1 hour
- ☐ 2. family history of insulin-dependent diabetes
- ☐ 3. internal fetal monitor tracing
- ☐ 4. irregular respirations, tremors, and hypothermia
- ☐ 5. large for gestational age

82. The nurse is caring for a newborn of a primiparous woman with insulin-dependent diabetes. When the mother visits the neonate at 1 hour after birth, the nurse explains to the mother that the neonate is being closely monitored for symptoms of hypoglycemia because of which reason?

- ☐ 1. increased use of glucose stores during a difficult labor and birth process
- ☐ 2. interrupted supply of maternal glucose and continued high neonatal

insulin production

- ☐ 3. a normal response that occurs during transition from intrauterine to extrauterine life
- ☐ 4. increased pancreatic enzyme production caused by decreased glucose stores

83. When caring for a neonate weighing 4,564 g (10 lb, 1 oz) born vaginally to a mother with diabetes, the nurse should assess the neonate for fracture of the:

- ☐ 1. clavicle
- ☐ 2. skull
- ☐ 3. wrist
- ☐ 4. rib cage

84. While caring for a neonate of a woman with diabetes soon after birth, the nurse has fed the newborn formula to prevent hypoglycemia. The nurse checks the neonate's blood glucose level, and it is 60 mg/dL (3.3 mmol/L), but the neonate continues to exhibit jitteriness and tremors. The nurse should **first**:

- ☐ 1. request a prescription for a blood calcium level.
- ☐ 2. administer glucose intravenously based on infant glucose level.
- ☐ 3. take the neonate's temperature and place him in the radiant warmer.
- ☐ 4. refeed the infant to continue to increase the blood glucose level.

85. The nurse is caring for a neonate weighing 4,536 g (10 lb) who was born via cesarean section 1 hour ago to a mother with insulin-dependent diabetes. She asks the nurse, "Why is my baby in the neonatal intensive care unit?" The nurse bases a response on the understanding that neonates of mothers with diabetes commonly develop which condition?

- ☐ 1. anemia
- ☐ 2. persistent pulmonary hypertension
- ☐ 3. hemolytic disease
- ☐ 4. hypoglycemia

86. While assessing a neonate weighing 3,175 g (7 lb) who was born at 39 weeks' gestation to a primiparous client who admits to opiate use during

pregnancy, which finding would alert the nurse to possible opiate withdrawal?

- ☐ 1. bradycardia
- ☐ 2. high-pitched cry
- ☐ 3. sluggishness
- ☐ 4. hypocalcemia

87. The nurse recognizes that parent teaching about complications of neonatal opioid exposure has been effective when the parents state that the baby may exhibit which gastrointestinal problem?

- ☐ 1. hypotonia
- ☐ 2. constipation
- ☐ 3. vomiting
- ☐ 4. abdominal distention

88. When teaching a primiparous client who used cocaine during pregnancy how to comfort her fussy neonate, the nurse can advise the mother to:

- ☐ 1. tightly swaddle the neonate.
- ☐ 2. feed the neonate extra, high-calorie formula.
- ☐ 3. keep the neonate in a brightly lit environment.
- ☐ 4. touch the baby only when he or she is crying.

89. A neonate born at 38 weeks' gestation is admitted to the neonatal nursery for observation. The neonate's mother, who is positive for human immunodeficiency virus (HIV) infection, has received no prenatal care. The mother asks the nurse if her neonate is positive for HIV. The nurse can tell the mother which information?

- ☐ 1. "More than 50% of neonates born to mothers who are positive for HIV will be positive at 18 months of age."
- ☐ 2. "An enlarged liver at birth generally means the neonate is HIV positive."
- ☐ 3. "A complete blood count analysis is the primary method for determining whether the neonate is HIV positive."
- ☐ 4. "We will test your baby now, but testing will need to be repeated for an

accurate diagnosis.”

90. When caring for a multiparous client who is human immunodeficiency virus (HIV) positive and asking to breast-feed her neonate as soon as possible, which instructions about breast milk should the nurse include in the teaching plan?

- ☐ 1. It may help prevent the spread of the HIV virus.
- ☐ 2. It contains antibodies that can protect the neonate from HIV.
- ☐ 3. It can be beneficial for the bonding process.
- ☐ 4. It has been found to contain the retrovirus HIV.

91. While caring for the neonate of a human immunodeficiency virus–positive mother, the nurse prepares to administer a prescribed vitamin K intramuscular injection at 1 hour after birth. Which action should the nurse do **first**?

- ☐ 1. Bathe the neonate.
- ☐ 2. Place the neonate under a radiant warmer.
- ☐ 3. Wash the injection site with povidone-iodine solution.
- ☐ 4. Wait until the first dose of antiretroviral medication is given.

92. A 6-hour-old neonate born at 38 weeks’ gestation by cesarean section after prolonged rupture of the membranes and a maternal oral temperature of 102°F (38.8°C) is being observed for signs and symptoms of infection. Which sign would alert the nurse to notify the healthcare provider (HCP)?

- ☐ 1. leukocytosis
- ☐ 2. apical heart rate of 132 bpm
- ☐ 3. behavioral changes
- ☐ 4. warm, moist skin

93. The nurse is caring for a neonate diagnosed with early-onset sepsis and is being treated with intravenous antibiotics. Which instruction will the nurse include in the parents’ teaching plan?

- ☐ 1. Wear protective gear near the isolation incubator.
- ☐ 2. Visit but do not touch the neonate.
- ☐ 3. Wash hands thoroughly before touching the neonate.
- ☐ 4. Wear a mask when holding the neonate.

94. A female neonate born vaginally at term with a cleft lip and cleft palate is admitted to the regular nursery. Which action should the nurse take the first time that the parents visit the neonate in the nursery?

- ☐ 1. Explain the surgical interventions that will be performed.
- ☐ 2. Stress that this defect is not life-threatening.
- ☐ 3. Emphasize the neonate's normal characteristics.
- ☐ 4. Reassure the parents about the success rate of the surgery.

95. After teaching the parents of a neonate born with a cleft lip and cleft palate about appropriate feeding techniques, the nurse determines that the mother needs further instruction when the mother makes which statement?

- ☐ 1. "I should clean her mouth each feeding."
- ☐ 2. "I should feed her in an upright position."
- ☐ 3. "I need to remember to burp her often."
- ☐ 4. "I may need to use a special nipple for feeding."

96. A male neonate born at 36 weeks' gestation is admitted to the neonatal intensive care nursery with a diagnosis of probable fetal alcohol syndrome (FAS). The mother visits the nursery soon after the neonate is admitted. Which instructions should the nurse expect to include when developing the teaching plan for the mother about FAS?

- ☐ 1. Withdrawal symptoms usually do not occur until 7 days postpartum.
- ☐ 2. Large-for-gestational-age size is common with this condition.
- ☐ 3. Facial deformities associated with FAS can be corrected by plastic surgery.
- ☐ 4. Symptoms of withdrawal include tremors, sleeplessness, and seizures.

97. Which characteristic should the nurse teach the mother about her neonate diagnosed with fetal alcohol syndrome (FAS)?

- ☐ 1. Neonates are commonly listless and lethargic.
- ☐ 2. The IQ scores are usually average.
- ☐ 3. Hyperactivity and speech disorders are common.
- ☐ 4. The mortality rate is 70% unless treated.

98. A newborn is diagnosed with fetal alcohol syndrome. The nurse is teaching this mother what to expect when she goes home with her baby. The

nurse determines the mother needs further instruction when she makes which statement?

- ☐ 1. "The way my baby's face looks now will stay that way."
- ☐ 2. "My baby may be irritable as a newborn."
- ☐ 3. "I may need some help coping with my newborn."
- ☐ 4. "My baby will be fine soon after we are home."

99. The father of a neonate diagnosed with gastroschisis tells the nurse that his wife had planned on breast-feeding the neonate. Which information should the nurse include in the preoperative teaching plan about feeding the neonate?

- ☐ 1. The neonate will remain on nothing-by-mouth (NPO) status until after surgery.
- ☐ 2. An iron-fortified formula will be given before surgery.
- ☐ 3. The neonate will need total parenteral nutrition for nourishment.
- ☐ 4. The mother may breast-feed the neonate before surgery.

100. The nurse is developing a plan of care for a neonate who is to undergo gastroschisis surgery. What should be included? Select all that apply.

- ☐ 1. prevention of hypothermia
- ☐ 2. maintenance of fluid and electrolyte balance
- ☐ 3. controlling preoperative pain
- ☐ 4. prevention of infection
- ☐ 5. providing developmental care

101. While caring for a male neonate diagnosed with gastroschisis, the nurse observes that the parents seem hesitant to touch the neonate because of his appearance. The nurse determines that the parents are **most** likely experiencing which stage of grief?

- ☐ 1. denial
- ☐ 2. shock
- ☐ 3. bargaining
- ☐ 4. anger

102. Which instructions should the nurse give to the parents of a neonate

diagnosed with hyperbilirubinemia who is receiving phototherapy?

- ☐ 1. Keep the neonate's eyes completely covered.
- ☐ 2. Use a regular diaper on the neonate.
- ☐ 3. Offer feedings every 4 hours.
- ☐ 4. Check the rectal temperature every 8 hours.

103. While caring for a term neonate who has been receiving phototherapy for 8 hours, the nurse should notify the healthcare provider (HCP) if which finding is noted?

- ☐ 1. bronze-colored skin
- ☐ 2. maculopapular chest rash
- ☐ 3. urine specific gravity of 1.018
- ☐ 4. absent Moro reflex

104. The nurse is caring for a neonate at 38 weeks' gestation when the nurse observes marked peristaltic waves on the neonate's abdomen. After this observation, the neonate exhibits projectile vomiting. The nurse notifies the healthcare provider (HCP) because these signs are indicative of which problem?

- ☐ 1. esophageal atresia
- ☐ 2. pyloric stenosis
- ☐ 3. diaphragmatic hernia
- ☐ 4. hiatal hernia

105. The nurse is caring for a term neonate who is diagnosed with patent ductus arteriosus. While performing a physical assessment of the neonate, the nurse anticipates that the neonate will exhibit which signs?

- ☐ 1. decreased cardiac output with faint peripheral pulses
- ☐ 2. profound cyanosis over most of the body
- ☐ 3. loud cardiac murmur through systole and diastole
- ☐ 4. harsh systolic murmur with a palpable thrill

106. Assessment of a term neonate at 8 hours after birth reveals tachypnea, diminished femoral pulses, and poor lower body perfusion. The nurse notifies the healthcare provider (HCP) based on the interpretation that these symptoms are associated with which complication?

- ☐ 1. coarctation of the aorta
- ☐ 2. atrioventricular septal defect
- ☐ 3. pulmonary atresia
- ☐ 4. transposition of the great arteries

107. The nurse is caring for a 2-day-old neonate in the postanesthesia care unit 30 minutes after surgical correction for the cardiac defect, transposition of the great vessels. Which finding would alert the nurse to notify the healthcare provider (HCP)?

- ☐ 1. oxygen saturation of 90%
- ☐ 2. pale pink extremities
- ☐ 3. warm, dry skin
- ☐ 4. femoral pulse of 90 bpm

108. Assessing a neonate at 8 hours of age, the nurse records findings on the medical record below:

Nurses Progress Notes

Time	1100
Respiration	92, no nasal flaring, retractions, grunting
Heart rate	128, no murmur noted
Temperature	98.9°F (32.3°C)

At 1130, the nurse notices the neonate has central cyanosis, and the respiratory rate is now 102; no nasal flaring, no retractions, or grunting was noted, and breath sounds were clear. The nurse should:

- ☐ 1. change the neonate's position.
- ☐ 2. encourage the baby to cry.

- ☐ 3. notify the healthcare provider.
- ☐ 4. suction the nose and mouth.

109. The nurse is performing an admission assessment on a neonate and finds the femoral pulses to be weaker than the brachial and radial pulses. The **next** nursing action should be to:

- ☐ 1. call for a cardiac consult.
- ☐ 2. note and tell the healthcare provider (HCP) when rounds are made.
- ☐ 3. place the neonate in reverse Trendelenburg position.
- ☐ 4. take the neonate's blood pressure in all four extremities.

110. A neonate is 4 hours of age. The nursing assessment reveals a heart murmur. The nurse should:

- ☐ 1. call the healthcare provider immediately.
- ☐ 2. continue routine care.
- ☐ 3. feed the neonate.
- ☐ 4. further assess for signs of distress.

111. During change of shift report, it was reported that a neonate was experiencing subcostal retractions. Identify where you would expect to see the retractions.

112. A woman has just given birth to a stillborn baby at 39 weeks' gestation. What is the **most** appropriate response for the nurse to make at this time?

- ☐ 1. "I understand how you must feel."
- ☐ 2. "I am sorry for your loss."
- ☐ 3. "Time heals all wounds."
- ☐ 4. "You can have another baby."

Managing Care, Quality, and Safety of Neonatal Clients

113. The nurse is making clinical rounds on a group of clients in a newborn nursery. Which infant is at **greatest** risk of developing respiratory distress syndrome (RDS)?

- ☐ 1. a neonate born at 36 weeks' gestation
- ☐ 2. a neonate born by cesarean section
- ☐ 3. a neonate experiencing apneic episodes
- ☐ 4. a neonate who is 42 weeks' gestation

114. The nurse has received a shift report on a group of newborns. The nurse should make rounds on which client **first**?

- ☐ **1.** a newborn who is large for gestational age (LGA) who needs a repeat blood glucose prior to the next feeding in 15 minutes
- ☐ **2.** a neonate born at 36 weeks' gestation weighing 5 lb (2,270 g) who is due to breast-feed for the first time in 15 minutes
- ☐ **3.** a neonate who was born 24 hours ago by cesarean section and had a respiratory rate of 62, 30 minutes ago
- ☐ **4.** a newborn who had a borderline low temperature and was double-wrapped with a hat half an hour ago to bring up the temperature

115. The nurse is caring for a 2-hour-old, full-term, breast-feeding newborn. The nurse notes the following assessments: apical pulse, 122 bpm; axilla temperature, 96.6°F (35.9°C); jitteriness. Based on this assessment, the nurse should **first**:

- ☐ **1.** assist the newborn to breast-feed.
- ☐ **2.** notify the healthcare provider (HCP).
- ☐ **3.** obtain a blood glucose sample.
- ☐ **4.** place the newborn under a radiant heater.

116. The nurse is assigned to care for four mothers and their term newborns. Which mother and newborn couplet requires the nurse's attention **first**?

- ☐ **1.** Mother: fundus firm 2 cm below umbilicus, minimal lochia rubra. Infant: color is pink on room air, respirations 67 breaths/min; bilateral crackles on auscultation.
- ☐ **2.** Mother: fundus firm 3 cm above umbilicus and to the right, moderate rubra lochia. Infant: color pink when active, currently dusky while quiet, respirations 70 breaths/min.
- ☐ **3.** Mother: fundus firm 1 cm above umbilicus, small amount lochia rubra. Infant: color pink with acrocyanosis, respirations 68 breaths/min and intermittent expiratory grunting.
- ☐ **4.** Mother: fundus firm at umbilicus, small amount lochia rubra. Infant: pale pink, quiet alert; respirations 65 breaths/min; periodic breathing noted.

117. The nurse in a postpartum couplet room is making rounds prior to

ending the shift. Which findings indicate that the safety needs of the clients have been met? Select all that apply.

- ☐ 1. infant lying on abdomen
- ☐ 2. security tags in place
- ☐ 3. identification system on mother and infant
- ☐ 4. bulb syringe within sight
- ☐ 5. someone in room able to care for infant
- ☐ 6. infant in the mother's arms, both asleep

118. After receiving change of shift report in the normal newborn nursery, which neonate should the nurse see **first**?

- ☐ 1. neonate A, ½ hour of age with occasional respiratory grunting
- ☐ 2. neonate B, 4 hours of age with a blood glucose of 25 (1.38 mmol/L)
- ☐ 3. neonate C, 12 hours of age with a temperature of 97.4°F (36.4°C)
- ☐ 4. neonate D, 24 hours of age with no urine output for past 12 hours

119. The newborn nurse has just received shift report about a group of newborns and is to receive another admission in 30 minutes. In order to provide the safest care and plan for the new admission, the nurse should do which tasks in order of first to last? All options must be used.

1. Move quickly from room to room, and assess all clients.

2. Check the room to which the new client will be admitted to be sure all supplies and equipment are available.

3. Log on to the clinical information system, and determine if there are new prescriptions.

4. Review notes from shift report, and prioritize all clients; make rounds on the most critical first.

120. The charge nurse in the newborn nursery has an unlicensed assistive personnel (UAP) with her for the shift. Under their care are eight babies rooming in with their mothers, and one infant in the nursery for the night on tube feedings. There is a new client whose infant will be brought to the nursery in 15 minutes. Which tasks would the nurse assign to the UAP? Select all that apply.

- ☐ 1. newborn admission
- ☐ 2. vital signs on all stable infants
- ☐ 3. tube feeding
- ☐ 4. document feedings of infants
- ☐ 5. record voids/stools
- ☐ 6. bath and initial feeding for new admission

Answers, Rationales, and Test-Taking Strategies

*The answers and rationales for each question follow below, along with keys () to the client need (CN) and cognitive level (CL) for each question. In addition, you will also see a glossary icon () highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 12–23 and pages 35–36 in Part 1 of this book.*

Neonatal Care

1. 2. Breast-fed infants should eat within the first hour of life and approximately every 2 to 3 hours. Successful breast-feeding will likely require sustained support, encouragement, and instruction from the nurse.

Information on SIDS, infant bathing, and sleep-wake cycles are also important topics for the new parent, but can be done at any time prior to discharge.

CN: Health promotion and maintenance; CL: Analyze

2. 2. The concern with this infant is sepsis based on prolonged rupture of membranes before birth. Blood cultures would provide an accurate diagnosis of sepsis but will take 48 hours from the time drawn. Frequent monitoring of infant vital signs, looking for changes, and maintaining contact with the parents is also part of care management while awaiting culture results. Continuing with vital signs, voiding, stooling, and eating every 4 hours is the standard of care for a normal newborn, but a respiratory rate greater than 60, grunting, and occasional flaring are not normal. Although not normal, the need for the intensive care unit is not warranted as newborns with sepsis can be treated with antibiotics at the maternal bedside. The CBC does not establish the diagnosis of sepsis, but the changes in the WBC levels can identify an infant at risk. Many experts suggest that waiting until an infant is 6 to 12 hours old to draw a CBC will give the most accurate results.

CN: Reduction of risk potential; CL: Synthesize

3. 2. The neonate should be kept away from drafts, such as from air conditioning vents, which may cause heat loss by convection. Evaporation is one of the most common mechanisms by which the neonate will lose heat, such as when the moisture on the newly born neonate's body is converted to vapor. Drying the infant prevents heat loss by evaporation. Keeping infants away from outside windows helps prevent heat loss by radiation defined as heat loss between solid objects that are not in contact with one another such as walls and windows. Conduction is when heat is transferred between solid objects in contact with one another, such as when a neonate comes in contact with a cold mattress or scale. Placing the infant in a radiant warmer or skin-to-skin reduces heat loss from conduction.

CN: Reduction of risk potential; CL: Synthesize

4. 135 mg

The recommended dose of ampicillin for a neonate is 100 mg/kg/dose. First, determine the neonate's weight in kilograms, and then multiply the kilograms

by 100 mg. The nurse should use this formula:

$$1,000 \text{ g} = 1 \text{ kg}$$

$$1,350 \text{ g} = 1.35 \text{ kg}$$

$$100 \text{ mg} \times 1.35 \text{ kg} = 135 \text{ mg/kg}$$

 CN: Pharmacological and parenteral therapies; CL: Apply

5. 3. Adding humidity to the incubator adds moisture to the ambient air, which helps to decrease the insensible water loss. Bathing and the use of eye patches has no impact on insensible water loss. The use of a radiant warmer will increase the insensible water loss by drawing moisture out of the skin.

 CN: Reduction of risk potential; CL: Synthesize

6. 3. Neonates that are septic use glucose at an increased rate. During the time the IV is not infusing, the neonate is using the limited glucose stores available to a preterm neonate and may deplete them. Hypoglycemia is too little glucose in the blood; without the constant infusion of IV glucose, hypoglycemia will result. Fevers and hyperkalemia are not related to glucose levels. Tachycardia is the result of untreated hypoglycemia.

 CN: Reduction of risk potential; CL: Analyze

7. 1. This 3-day-old neonate's weight loss falls within a normal range, and therefore no action is needed at this time. Full-term neonates tend to lose 5% to 10% of their birth weight during the first few days after birth, most likely because of minimal nutritional intake. With bottle-feeding, the neonate's intake varies from one feeding to another. Typically, neonates regain any weight loss by 7 to 10 days of life. If the weight loss continues after that time, the **HCP**  should be called.

 CN: Health promotion and maintenance; CL: Synthesize

8. 240 calories

Eight feedings \times 45 mL per feeding equals 360 mL. $360 \text{ mL} \times 20 \text{ cal/30 mL}$

= 240 calories.

CN: Basic care and comfort; CL: Apply

9. 4. Placing an infant on a mother's bare chest or abdomen facilitates transition to extrauterine life and is the preferred method of thermoregulation for stable infants. A radiant warmer should be used if an infant is unstable and needs medical intervention. Blankets may be placed over a newborn and mom's chest. A hat may be added to prevent heat loss from the head, but these methods are supplemental to skin-to-skin care.

CN: Health promotion and maintenance; CL: Apply

10. 1. For vitamin K synthesis in the intestines to begin, food and normal intestinal flora are needed. However, at birth, the neonate's intestines are sterile. Therefore, vitamin K is administered via injection to prevent a vitamin K deficiency that may result in a bleeding tendency. When administered, vitamin K promotes formation in the liver of clotting factors II, VII, IX, and X. Neonates are not normally susceptible to clotting disorders, unless they are diagnosed with hemophilia or demonstrate a deficiency of or a problem with clotting factors. Hemolysis of fetal red blood cells does not destroy vitamin K. Hemolysis may be caused by Rh or ABO incompatibility, which leads to anemia and necessitates an exchange transfusion. Vitamin K synthesis occurs in the intestines, not the liver.

CN: Pharmacological and parenteral therapies; CL: Evaluate

11. 3. Currently, touch is believed to be the most highly developed sense at birth. It is probably why neonates respond well to touch. Auditory sense typically is relatively immature in the neonate, as evidenced by the neonate's selective response to the human voice. By 4 months, the neonate should turn his eyes and head toward a sound coming from behind. Visual sense tends to be relatively immature. At birth, visual acuity is estimated at 20/100 to 20/150, but it improves rapidly during infancy and toddlerhood. Taste is well developed, with a preference toward glucose; however, touch is more developed at birth.

CN: Health promotion and maintenance; CL: Synthesize

12. 4. Healthy infants are weighed during their visits to their **healthcare**

provider (HCP) , so it is not necessary to monitor weights at home. Infants may require one to three feedings during the night initially. By 3 months, 90% of babies sleep through the night. Projectile vomiting may indicate pyloric stenosis and should not be seen in a normal newborn. Bottle-fed infants may stool one to three times daily.

CN: Health promotion and maintenance; CL: Evaluate

13. 1. The head and neck are best supported in a rear-facing seat in infants and toddlers, and infants should remain rear facing for as long possible until they outgrow their car seat. In the United States, the American Academy of Pediatrics recommends a rear-facing car seat for children younger than 2 years. The middle of the back seat is safest for a car seat. Because plastic can become brittle over time, car seats have an expiration date that must be checked before use. Ten years would generally be outside of most car seats' expiration dates.

CN: Health promotion and maintenance; CL: Evaluate

14. 1. The nurse should inform the mother that baby powder can enter the neonate's lungs and result in pneumonia secondary to aspiration of the particles. The best prevention for diaper rash is frequent diaper changing and keeping the neonate's skin dry. The disposable diapers have moisture-collecting materials and generally do not adhere to the skin unless the diaper becomes saturated. Typically, allergies are not associated with the use of baby powder in neonates.

CN: Reduction of risk potential; CL: Synthesize

15. 4. The mother needs further instruction when she says that a yellowish crust should be removed with water. The yellowish crust is normal and indicates scar formation at the site. It should not be removed because to do so might cause increased bleeding. The petroleum gauze prevents the diaper from sticking to the circumcision site, and it may fall off in the diaper. If this occurs, the mother should not attempt to replace it but should simply apply plain petroleum jelly to the site. The gauze should be left in place for 24 hours, and the mother should continue to apply petroleum jelly with each diaper change for 48 hours after the procedure. A few drops of oozing blood is normal, but if the amount is greater than a few drops, the mother should

apply pressure and contact the **healthcare provider (HCP)** 📖. Any bleeding after the first day should be reported.

🔑 CN: Reduction of risk potential; CL: Evaluate

16. 3. The mother demonstrates understanding of the discharge instructions when she says that she should contact the **HCP** 📖 if the baby has a liquid stool with a watery ring, because this indicates diarrhea. Infants can become dehydrated very quickly, and frequent diarrhea can result in dehydration. Normally, babies fall asleep easily after a feeding because they are satisfied and content. Spitting up a tablespoon of formula is normal. However, projectile or forceful vomiting in larger amounts should be reported. Bottle-fed infants typically pass one to two light brown stools each day.

🔑 CN: Reduction of risk potential; CL: Evaluate

17. 1. Placing the neonate on his back after the feeding is recommended to minimize the risk for sudden infant death syndrome (SIDS). Placing the neonate on the abdomen after feeding has been associated with SIDS. The mother should bubble or burp the baby more than once during a feeding including at least after ½ oz (15 mL) of formula has been taken and then again when the baby is finished. Waiting until the baby has eaten 1 oz (30 mL) of formula can lead to regurgitation. The entire nipple should be placed on top of the baby's tongue and into the mouth to prevent excessive air from being swallowed. The nipple is pointed directly into the mouth, not toward the neonate's palate, to provide adequate sucking.

🔑 CN: Reduction of risk potential; CL: Evaluate

18. 1. In a neonate, the lateral aspect of the heel is the most appropriate site for obtaining a blood specimen. Using this area prevents damage to the calcaneus bone, which is located in the middle of the heel. The middle of the heel is to be avoided because of the increased risk for damaging the calcaneus bone located there. The middle of the foot contains the medial plantar nerve and the medial plantar artery, which could be injured if this site is selected. Using the base of the big toe as the site for specimen collection would cause a great deal of discomfort for the neonate; therefore, it is not the preferred site.

 CN: Reduction of risk potential; CL: Apply

19. 2. After circumcision with a Plastibell, the most commonly recommended procedure is to clean the circumcision site with warm water with each diaper change. Other treatments are necessary only if complications, such as an infection, develop. Antibacterial soap or diluted hydrogen peroxide may cause pain and is not recommended. Povidone-iodine solution may cause stinging and burning, and therefore its use is not recommended.

 CN: Health promotion and maintenance; CL: Apply

20. 2. As part of the neonate's physiologic adaptation to birth at 90 minutes after birth the neonate typically is in the rest or sleep phase. During this time, the heart and respiratory rates slow and the neonate sleeps, unresponsive to stimuli. At this time, the mother should rest and allow the neonate to sleep. Feedings should be given during the first period of reactivity, considered the first 30 minutes after birth. During this period, the neonate's respirations and heart rate are elevated. Getting to know the neonate typically occurs within the first hour after birth and then when the neonate is awake and during feedings. Changing the neonate's diaper can occur at any time, but at 90 minutes after birth, the neonate is usually in a deep sleep, unresponsive, and probably has not passed any meconium.

 CN: Health promotion and maintenance; CL: Apply

Physical Assessment of the Neonatal Client

21. 1. When assessing the incurving of the trunk tests for automatic reflexes in the newborn, the nurse places the infant horizontally and in a prone position with one hand, and strokes the side of the newborn's trunk from the shoulder to the buttocks using the other hand. If the reflex is present, the newborn's trunk curves toward the stimulated side. Answer 2 shows a figure for testing for a stepping response. Answer 3 shows a figure for testing for a tonic neck reflex. Answer 4 shows a figure for testing for the Moro (startle) reflex.

 CN: Physiological adaptation; CL: Apply

22. 2. The baby is displaying a normal Moro reflex that occurs with a sudden loss of support and requires no intervention. Calling a code, placing the neonate on seizure precautions, and starting supplemental oxygen are not necessary for a normally occurring reflex.

 CN: Basic care and comfort; CL: Synthesize

23. 2. If an infant is not breathing after the initial steps of resuscitation, the next thing the nurse must do is begin positive pressure ventilation. Apgar scores are an evaluation of the neonate's status at 1 and 5 minutes of life. Waiting to restore respirations until after assigning an Apgar score would be a waste of valuable time. Oxygen alone does little good if the infant is not breathing. Chest compressions must be accompanied by adequate oxygenation.

 CN: Physiological adaptation; CL: Synthesize

24. 3. The neonate has a heart rate greater than 100, which earns him 2 points. His respiratory rate of 70 is equivalent to a 2 on the scale. His flaccid muscle tone is equal to 0 on the scale. The lack of response to stimulus also equals 0, as does his overall pale white color. Thus, the total score equals 4.

CN: Basic care and comfort; CL: Apply

25. 1. After performing vigorous suctioning, the nurse must watch for bradycardia due to potential vagus nerve stimulation. Rapid eye movement is not associated with vagus nerve stimulation. Vagal stimulation will not cause seizures or tachypnea.

CN: Reduction of risk potential; CL: Analyze

26. 2. There is a correlation between café au lait spots and the development of neurofibromatosis. Acrocyanosis is a normal finding of bluish hands and feet as a result of poor capillary perfusion. Port-wine nevus and strawberry hemangiomas are a collection of dilated capillaries and are not associated with any other disease process.

CN: Reduction of risk potential; CL: Analyze

27. 2,3,4. Holding the neonate steady and in the proper position will help ensure a safe and accurate lumbar puncture. The neonate is usually held in a “C” position to open the spaces between the vertebral column. This position puts the neonate at risk for airway obstruction. Thus, ensuring the patency of the airway is the first priority, and the nurse should observe the neonate for adequate ventilation. Maintaining a sterile field is important to avoid infection in the neonate. It is not necessary to administer antibiotics or obtain a serum glucose level during the procedure.

CN: Safety and infection control; CL: Synthesize

28. 3. Normally, the umbilical cord has two umbilical arteries and one vein. When a neonate is born with only one artery and one vein, the nurse should notify the **HCP**  for further evaluation of cardiac anomalies. Other common congenital problems associated with a missing artery include renal anomalies, central nervous system lesions, tracheoesophageal fistulas, trisomy 13, and trisomy 18. Respiratory anomalies are associated with dyspnea and respiratory distress; musculoskeletal anomalies include fractures

or dislocated hip; and facial anomalies are associated with fetal alcohol syndrome or Down syndrome, not a missing umbilical artery.

CN: Reduction of risk potential; CL: Analyze

29. 3. The most appropriate response would be to explain that the vaginal spotting in female neonates is associated with hormones received from the mother. Estrogen is believed to cause slight vaginal bleeding or spotting in the female neonate. The condition disappears spontaneously, so there is no need for concern. Telling the mother that it is of no concern does not allay the mother's worry. The vaginal spotting is related to hormones received from the mother, not to swallowing blood during the birth or hemorrhagic disease of the neonate. Anemia is associated with hemorrhagic disease.

CN: Health promotion and maintenance; CL: Synthesize

30. 1. Caput succedaneum is common after the use of a vacuum extractor to assist the client's expulsion efforts. This edema may persist up to 7 days. Vacuum extraction is not associated with cephalohematoma. Maternal lacerations may occur, but they are more common when forceps are used. Neonatal intracranial hemorrhage is a risk with both vacuum extraction and forceps births, but it is not a common finding.

CN: Health promotion and maintenance; CL: Analyze

31. 4. The mother needs further instruction if she says the molding can result in brain damage. Brain damage is highly unlikely. Molding occurs during vaginal birth when the cranial bones tend to override or overlap as the head accommodates to the size of the mother's birth canal. The amount and duration of pressure on the head influence the degree of molding. Molding usually disappears in a few days without any special attention.

CN: Health promotion and maintenance; CL: Evaluate

32. 3. Sole creases covering the entire foot are indicative of a term neonate. If the neonate's ear is lying flat against the head, the neonate is most likely preterm. An absence of rugae in the scrotum typically suggests a preterm neonate. A square window sign angle of 0 degrees occurs in neonates of 40 to 42 weeks' gestation. A 90-degree square window angle suggests an immature neonate of approximately 28 to 30 weeks' gestation.

CN: Health promotion and maintenance; CL: Apply

33. 2. An expiratory grunt is significant and should be reported promptly because it may indicate respiratory distress and the need for further intervention such as oxygen or resuscitation efforts. The presence of a red reflex in the eyes is normal. An absent red reflex may indicate congenital cataracts. A respiratory rate of 45 breaths/min and a prominent xiphoid process are normal findings in a term neonate.

CN: Reduction of risk potential; CL: Synthesize

34. 3. The tonic neck reflex, also called the fencing position, is present when the neonate turns the head to the left side, extends the left extremities, and flexes the right extremities. This reflex disappears in a matter of months as the neonatal nervous system matures. The stepping reflex is demonstrated when the infant is held upright near a hard, firm surface. The prone crawl reflex is demonstrated when the infant pulls both arms but does not move the chin beyond the elbows. When the infant extends and abducts the arms and legs with the toes fanning open, this is a normal Babinski's reflex.

CN: Health promotion and maintenance; CL: Apply

35. 2. Convergent strabismus is common during infancy until about age 6 months because of poor oculomotor coordination. The neonate has peripheral vision and can fixate on close objects for short periods. The neonate can also perceive colors, shapes, and faces. Neonates can focus on light and should blink or close their eyes in response to light. However, this is not associated with strabismus. An absent red reflex or white areas over the pupils, not strabismus, may indicate congenital cataracts. Most neonates cannot focus well or accommodate for distance immediately after birth.

CN: Health promotion and maintenance; CL: Apply

36. 3. A single crease across the palm (simian crease) is most commonly associated with chromosomal abnormalities, notably Down syndrome. Deep creases across the soles of the feet is a normal finding in a term neonate. Frequent sneezing in a term neonate is normal. This occurs because the neonate is a nose breather and sneezing helps to clear the nares. An absence of lanugo on the skin of a term neonate is a normal finding.

 CN: Reduction of risk potential; CL: Synthesize

37. 1,5,6. Phenylketonuria, an inherited autosomal recessive disorder, involves the body's inability to metabolize the amino acid phenylalanine. A diet low in phenylalanine must be followed. Such foods as meats, eggs, and milk are high in phenylalanine. Assistance from a dietitian is commonly necessary to keep phenylalanine levels low and to provide the essential amino acids necessary for cell function and tissue growth. With autosomal recessive disorders, future children will have a 25% chance of having the disease, a 50% chance of carrying the disease, and a 25% chance of being free of the disease. If a diet low in phenylalanine is followed until brain growth is complete (sometime in adolescence), the child should achieve normal intelligence.

 CN: Health promotion and maintenance; CL: Evaluate

38. 1. Periods of apnea lasting longer than 20 seconds, mild cyanosis, and a heart rate of <100 bpm (bradycardia) are associated with a potentially life-threatening event and subsequent respiratory arrest. The neonate needs further evaluation by the **HCP**. Pneumonia is associated with tachycardia, anorexia, malaise, cyanosis, diminished breath sounds, and crackles. Intraventricular hemorrhage is associated with prematurity. Assessment findings include bulging fontanelles and seizures. Epiglottitis is a bacterial form of croup. Assessment findings include inspiratory stridor, cough, and irritability. It occurs most commonly in children age 3 to 7 years.

 CN: Reduction of risk potential; CL: Analyze

39. 4. Normally, the anterior fontanelle closes between ages 12 and 18 months. Premature closure (craniostenosis or premature synostosis) prevents proper growth and expansion of the brain, resulting in an intellectual disability. The posterior fontanel typically closes by ages 2 to 3 months.

 CN: Health promotion and maintenance; CL: Apply

40. 2. Corneas of unequal size should be reported because this may indicate congenital glaucoma. An absence of tears is common because the neonate's lacrimal glands are not yet functioning. The neonate's pupils normally constrict when a bright light is focused on them. The finding

implies that light perception and visual acuity are present, as they should be after birth. A red circle on the pupils is seen when a penlight or ophthalmoscope's light shines onto the retina and is a normal finding. Called the red reflex, this indicates that the light is shining onto the retina.

CN: Reduction of risk potential; CL: Synthesize

41. 3. At 24 hours of age, the neonate is probably in a state of deep sleep, as evidenced by the closed eyes, lack of eye movements, normal skin color, and normal heart rate and respiratory rate. Jitteriness, a high-pitched cry, and tremors are associated with drug withdrawal. The first period of reactivity occurs in the first 30 minutes after birth, evidenced by alertness, sucking sounds, and rapid heart rate and respiratory rate. There is no evidence to suggest respiratory distress because the neonate's respiratory rate of 35 breaths/min is normal.

CN: Health promotion and maintenance; CL: Analyze

42. 4. The condition in which the urinary meatus is located on the ventral surface of the penis, termed hypospadias, occurs in 1 of every 500 male infants. Circumcision is delayed until the condition is corrected surgically, usually between 6 and 12 months of age. Phimosis is an inability to retract the prepuce at an age when it should be retractable or by age 3 years. Phimosis may necessitate circumcision or surgical intervention. Hydrocele is a painless swelling of the scrotum that is common in neonates. It is not a contraindication for circumcision. Epispadias occurs when the urinary meatus is located on the dorsal surface of the penis. It is extremely rare and is commonly associated with bladder exstrophy.

CN: Reduction of risk potential; CL: Analyze

The Preterm Neonate

43. 1,3,4,5. Kangaroo care is skin-to-skin holding of a neonate by one of the parents. Research has shown increased bonding, physiologic stability, decreased length of stay, and improved breast-feeding for neonates who experience this method of holding. Research has not shown an increase in IQ as a developmental outcome. The experience is usually limited to 1 to 2 hours, two to three times per day.

 CN: Health promotion and maintenance; CL: Apply

44. 4. When receiving oxygen by mask, the neonate is placed on the back with the neck slightly extended, in the “sniffing” or neutral position. This position optimizes lung expansion and places the upper respiratory tract in the best position for receiving oxygen. Placing a small rolled towel under the neonate’s shoulders helps to extend the neck properly without overextending it. Once stabilized and transferred to an isolette in the intensive care unit, the neonate can be positioned in the prone position, which allows for lung expansion in the oxygenated environment. Placing the neonate on the left side does not allow for maximum lung expansion. Also, slightly flexing the neck interferes with opening the airway. Placing the neonate on the back with the head turned to the left side does not allow for lung expansion. Placing the neonate on the abdomen interferes with proper positioning of the oxygen mask.

 CN: Pharmacological and parenteral therapies; CL: Synthesize

45. 1. Chest compressions should be alternated with ventilation to ensure breathing and circulation. Two fingers or two thumbs encircling hands, not the palm of the hand, are used to compress a neonate’s sternum. The chest is compressed 100 to 120 times/min. The proper technique recommended by the Neonatal Resuscitation Program is to use enough pressure to depress the sternum to a depth of approximately one-third of the anterior-posterior diameter of the chest.

 CN: Physiological adaptation; CL: Apply

46. 1. Whenever oxygen is administered, it should be humidified to prevent drying of the nasal passages and mucous membranes. Because the neonate is under a radiant warmer, a stocking cap is not necessary. Temperature, continuously monitored by a skin probe attached to the radiant warmer, is recorded every 30 to 60 minutes initially. Although the oxygen concentration in the hood requires close monitoring and measurement of blood gases, checking the blood glucose level is not necessary.

 CN: Pharmacological and parenteral therapies; CL: Apply

47. 3. The neonate is at high risk for sepsis due to exposure to the mother’s

infection. Temperature instability in a neonate at 38 weeks' gestation is an early sign of sepsis. Other signs include tachycardia, decreased muscle tone, acidosis, apnea, respiratory distress, hypotension, poor feeding behaviors, vomiting, and diarrhea. Late signs of infection include jaundice, seizures, enlarged liver and spleen, respiratory failure, and shock. Alkalosis is not typically seen in neonates who develop sepsis. Acidosis and respiratory distress may develop unless treatment such as antibiotics is started. A positive Babinski's reflex is a normal finding and does not need to be reported.

CN: Reduction of risk potential; CL: Analyze

48. 1. With an absent apical pulse left of the midclavicular line accompanied by cyanosis, grunting, and diminished breath sounds, the neonate is most likely experiencing pneumothorax. Pneumothorax occurs when alveoli are overdistended and subsequently the lung collapses, compressing the heart and lung and compromising the venous return to the right side of the heart. This condition can be confirmed by x-ray. An echocardiogram would be indicated if the chest x-ray did not reveal a respiratory cause for the problem or suggested a cardiac problem. Repositioning the infant may open the airway, and obtaining blood studies for infection will rule that out, but until pneumothorax is resolved, the other symptoms will continue.

CN: Physiological adaptation; CL: Synthesize

49. 2. RDS, previously called hyaline membrane disease, is a developmental condition involving a decrease in lung surfactant leading to improper expansion of the lung alveoli. Surfactant contains a group of surface-active phospholipids, of which one component—lecithin—is the most critical for alveolar stability. Surfactant production peaks at about 35 weeks' gestation. This syndrome primarily attacks preterm neonates, although it can also affect term and postterm neonates. Altered somatotropin secretion is associated with growth disorders such as gigantism or dwarfism. Altered testosterone secretion is associated with masculinization. Altered progesterone secretion is associated with spontaneous abortion during pregnancy.

CN: Physiological adaptation; CL: Apply

50. 2. RDS is a developmental condition that primarily affects preterm infants before 35 weeks' gestation because of inadequate lung development from deficient surfactant production. The development of placenta previa has little correlation with the development of RDS. Although excessive analgesia can depress the neonate's respiratory condition if it is given shortly before birth, the scenario presents no information that this has occurred. The neonate's sluggish respiratory activity postpartum is not the likely cause of RDS but may be a sign that the neonate has the condition.

CN: Reduction of risk potential; CL: Synthesize

51. 3. Oxygen should be humidified before administration to help prevent drying of the mucous membranes in the respiratory tract. Drying impedes the normal functioning of cilia in the respiratory tract and predisposes to mucous membrane irritation. Humidification of oxygen does not promote expansion of the immature lungs. Expansion is promoted by placing the infant in a prone position or providing the preterm infant with surfactant medication. Humidified oxygen does not prevent viral or bacterial pneumonia. In fact, in some nurseries, *Staphylococcus aureus* has been detected in moist environments and on the hands and nails of staff members, predisposing the neonate to pneumonia. Humidified oxygen does not improve blood circulation in the cardiac system.

CN: Pharmacological and parenteral therapies; CL: Apply

52. 4. Many intensive care units that care for high-risk neonates recommend that the mother pump her breasts, store the milk, and bring it to the unit so the neonate can be fed with it, even if the neonate is being fed by gavage. As soon as the neonate has developed a coordinated suck-and-swallow reflex, breast-feeding can begin. Secretory immunoglobulin A, found in breast milk, is an important immunoglobulin that can provide immunity to the mucosal surfaces of the gastrointestinal tract. It can protect the neonate from enteric infections, such as those caused by *Escherichia coli* and *Shigella* species. Some studies have also shown that breast-fed preterm neonates maintain transcutaneous oxygen pressure and body temperature better than bottle-fed neonates. There is some evidence that breast milk can

decrease the incidence of necrotizing enterocolitis. The preterm neonate does not need additional fat in the diet. However, some neonates may need an increased caloric intake. In such cases, breast milk can be fortified with an additive to provide additional calories. Neonates who are receiving oxygen can breast-feed. During feedings, supplemental oxygen can be delivered by nasal cannula.

CN: Health promotion and maintenance; CL: Apply

53. 1. ROP, previously called retrolental fibroplasia, is associated with multiple risk factors, including high arterial blood oxygen levels, prematurity, and very low birth weight (less than 1,500 g). In the early acute stages of ROP, the neonate's immature retinal vessels constrict. If vasoconstriction is sustained, vascular closure follows, and irreversible capillary endothelial damage occurs. Normal room air is at 21%. Acidosis, not alkalosis, is commonly seen in preterm neonates, but this is not related to the development of ROP. Phototherapy is not related to the development of ROP. However, during phototherapy, the neonate's eyes should be constantly covered to prevent damage from the lights.

CN: Reduction of risk potential; CL: Apply

54. 1. Because the retina may become detached with ROP, laser therapy has been used successfully in some medical centers to treat ROP. Anti-inflammatory eye drops may be used to treat seasonal allergies. ROP is not associated with glaucoma, so frequent testing is not necessary. Because the vessels of the eye are affected and not the corneas, corneal transplantation is not used.

CN: Physiological adaptation; CL: Apply

55. 1. Neonates who weigh less than 1,500 g or are born at less than 34 weeks' gestation are susceptible to IVH. Cranial ultrasound scanning can confirm the diagnosis. The spinal fluid will show an increased number of red blood cells. Arterial blood gas specimen collection is done to evaluate the neonate's oxygen saturation level. Skull radiographs are not commonly used because of the danger of radiation. Additionally, computed tomography scans have replaced the use of skull x-ray films because they can provide more definitive results. Complete blood count specimen collection is usually

performed to determine the hemoglobin, hematocrit, and white blood cell count. The results are not specific for IVH.

CN: Reduction of risk potential; CL: Apply

56. 3. A common finding of IVH is a bulging fontanelle. The most common site of hemorrhage is the periventricular subependymal germinal matrix, where there is a rich blood supply and where the capillary walls are thin and fragile. Rapid volume expansion, hypercarbia, and hypoglycemia contribute to the development of IVH. Other common manifestations include neurologic signs such as hypotonia, lethargy, temperature instability, nystagmus, apnea, bradycardia, decreased hematocrit, and increasing hypoxia. Seizures also may occur. Hyperbilirubinemia refers to an increase in bilirubin in the blood and may be seen if bleeding was severe.

CN: Physiological adaptation; CL: Analyze

57. 2,4,5. Nonnutritive sucking has been seen in infants as early as 28 weeks, and ultrasound examinations have shown thumb sucking in utero even earlier. Nonnutritive sucking provides oral stimulation and allows the baby to maintain the sucking reflex needed for breast- or bottle-feedings later. It does not teach the infant how to suck and swallow. Sucking is thought to help with gastric emptying by stimulating secretions of GI peptides. Moisture of the mucous membranes is an indication of adequate hydration, and nonnutritive sucking will not have an effect.

CN: Basic care and comfort; CL: Apply

58. 4. Indications of NEC include abdominal distention with gastric retention and vomiting. Other signs may include lethargy, irritability, positive blood culture in stool, absent or diminished bowel sounds, apnea, diarrhea, metabolic acidosis, and unstable temperature. A gastric residual of 1 mL is not significant. Jaundice of the face and chest is associated with the neonate's immature liver function and increased bilirubin, not NEC. Typically with NEC, the neonate would exhibit absent or diminished bowel sounds, not increased peristalsis.

CN: Physiological adaptation; CL: Analyze

59. 2. BPD is a chronic illness that may require prolonged hospitalization

and permanent assisted ventilation. The disease typically occurs in compromised very-low-birth-weight neonates who require oxygen therapy and assisted ventilation for treatment of respiratory distress syndrome. The cause is multifactorial, and the disease has four stages. The neonate's activities may be limited by the disease. Antibiotics may be prescribed and bronchodilators may be used, but these medications will not cure the chronic disease state. Seizure activity is associated with periventricular-intraventricular hemorrhage, not BPD.

 CN: Physiological adaptation; CL: Evaluate

60. 4. The client data support the diagnosis of pneumothorax, which would be confirmed with a chest x-ray. Pneumothorax is an accumulation of air in the thoracic cavity between the parietal and visceral pleurae and requires immediate removal of the accumulated air. Resolution is initiated with insertion of a chest tube connected to continuous negative pressure. The neonate does not need to be placed on a ventilator unless there is evidence of severe respiratory distress. The goal of treatment is to reinflate the collapsed lung. Administering bronchodilators through the nares or suctioning the neonate's nares would do nothing to aid in lung reinflation.

 CN: Physiological adaptation; CL: Synthesize

61. 3. Decreased protein or hypoproteinemia is a sign of overhydration, which can lead to patent ductus arteriosus or congestive heart failure. Bulging fontanelles, decreased serum sodium, decreased urine specific gravity, and decreased hematocrit are other signs of overhydration. Hypernatremia (increased serum sodium concentration) or increased urine specific gravity would suggest dehydration, not overhydration. Polycythemia evidenced by an elevated hematocrit would suggest hypoxia or congenital heart disorder.

 CN: Reduction of risk potential; CL: Analyze

62. 0.03 mg

$$2,950 \text{ g} = 2.95 \text{ kg}$$

$$2.95 \text{ kg} \times 0.01 \text{ mg} = 0.029 \text{ mg, rounded to } 0.03 \text{ mg}$$

 CN: Pharmacological and parenteral therapies; CL: Apply

The Postterm Neonate

63. 4. Increased respiratory rate and tremors are indicative of hypoglycemia, which commonly affects the postterm neonate because of depleted glycogen stores. There is no indication that the neonate has ineffective airway clearance, which would be evidenced by excessive amounts of mucus or visualization of meconium on the vocal cords. Lethargy, not tremors, would suggest infection or hyperthermia. Furthermore, the postterm neonate typically has difficulty maintaining temperature, resulting in hypothermia, not hyperthermia. Decreased cardiac output is not indicated, particularly because the neonate was born by cesarean section, which is not considered a difficult birth.

CN: Health promotion and maintenance; CL: Analyze

64. 2. A loose, watery stool in the diaper is indicative of diarrhea and needs immediate attention. The infant may become severely dehydrated quickly because of the higher percentage of water content per body weight in the neonate, compared with the adult. Frequent hiccups are considered normal in a neonate and do not warrant additional investigation. Pink papular vesicles (erythema toxicum) on the face are considered normal in a neonate and disappear without treatment. Dry, peeling skin is normal in a postterm neonate.

CN: Health promotion and maintenance; CL: Analyze

65. 2. Ortolani's maneuver involves flexing the neonate's knees and hips at right angles and bringing the sides of the knees down to the surface of the examining table. A characteristic click or "clunk," felt or heard, represents a positive Ortolani's sign, suggesting a possible hip dislocation. The nurse should notify the **HCP**  promptly because treatment is needed, while maintaining the dislocated hip in a position of flexion and abduction. It should be noted that many institutions now limit performing the Ortolani's maneuver to APNs or HCPs. Determining the length of the mother's labor provides no useful information related to the nurse's finding. Keeping the infant under the radiant warmer is necessary only if the neonate's temperature is low or unstable. Checking for hypoglycemia is not indicated at this time, unless the neonate is exhibiting jitteriness.

 CN: Reduction of risk potential; CL: Synthesize

66. 4. The priority problem for the neonate with probable MAS is impaired gas exchange related to the effects of respiratory distress. Obstruction of the airways may be complete or partial. Meconium aspiration may lead to pneumonia or pneumothorax. Establishing adequate respirations is the primary goal. Impaired skin integrity is a concern, but establishing and maintaining an airway and gas exchange is always the priority. Hypoglycemia tends to be a problem for large-for-gestational-age babies, not hyperglycemia. If the parents do not express interest or concern for the neonate, then risk for impaired parent-infant-child attachment may be appropriate once the airway is established.

 CN: Physiological adaptation; CL: Analyze

67. 1,4,5. The pneumothorax may affect cardiac output, thus affecting perfusion causing a decrease in blood pressure and changes in color from pallor to cyanosis. As the neonate attempts to compensate, bradycardia or tachycardia may be exhibited. A change in temperature and urinary output are very late signs of decompensation.

 CN: Physiological adaptation; CL: Analyze

The Neonate with Risk Factors

68. 2. Epinephrine is given for severe bradycardia and hypotension. An expected outcome would be an increased heart rate to a normal range. Epinephrine decreases renal blood flow, so a decrease in urine output would be expected. Epinephrine also stimulates alpha- and beta-adrenergic receptors, which do not offer pain relief or sedation.

 CN: Pharmacological and parenteral therapies; CL: Evaluate

69. 4. Neonates that are sick do not have the physical resources or energy to respond to all elements of the environment. The use of a constant touch provides comfort and only requires one response to a stimulus. To comfort a sick neonate, the care provider applies gentle, constant physical support or touch. Toys for distraction are not developmentally appropriate for a neonate. Sick neonates react to any stimulus; in responding, the sick neonate may have

increased energy demands and increased oxygen requirements. A musical mobile may be too much audio stimulation and thus increases energy and oxygen demands. Repetitive touching with a hand going off and on the neonate, as with stroking or patting, requires the neonate to respond to every touch, thus increasing energy and oxygen demands.

 CN: Basic care and comfort; CL: Synthesize

70. 2. Recommended pulse oximetry reading in a full-term neonate is 95% to 100%. The saturation reading of only 75% is an indication that the neonate is not adequately oxygenating in room air. Providing supplemental oxygen will increase the neonate's oxygen saturation. Increasing the IV rate will not improve the oxygen saturation. Documenting the finding and taking no action is not appropriate with a saturation of 75%. Wrapping and increasing the body temperature of the neonate may increase the saturation reading only if it is inaccurate due to cold extremities. Caution must be used because overheating a neonate can be harmful.

 CN: Reduction of risk potential; CL: Synthesize

71. 4. Neonates with heart failure may need calorie-dense formula to provide extra calories for growth. Fluids should not be restricted because the nutritional requirements are based on calories per ounce of formula. Decreasing fluid intake will decrease calories needed for growth. These neonates may have limited energy due to their heart condition but have a high caloric need to stimulate proper growth and development. The sodium level should be at a normal level to ensure adequate fluid and electrolyte balance unless prescribed by the **healthcare provider (HCP)**.

 CN: Health promotion and maintenance; CL: Create

72. 1. The indication for the use of indomethacin is to close a patent ductus arteriosus. Adverse effects include decreased renal blood flow, platelet dysfunction with coagulation defects, decreased GI motility, and an increase in necrotizing enterocolitis. Thus, increased bleeding time, decreased gastrointestinal function, and decreased renal output would be expected outcomes after the administration of indomethacin.

 CN: Pharmacological and parenteral therapies; CL: Evaluate

73. 2. A quiet environment with decreased stimulation is the best treatment for a drug-exposed neonate. The drug-exposed neonate has limited ability to deal with stress and cope with stimuli. Assessing vital signs with blood pressure every hour will disturb the neonate's rest periods and cause increased physical and psychological demands. Placement in a well-lighted environment and increasing eye contact can be overwhelming for the neonate and will increase the neonate's stress level.

CN: Physiological adaptation; CL: Apply

74. 1. To ensure client safety, the nurse should first write the results on the **medical record**, then read them back to the caller, and wait for the caller to confirm that the nurse has understood the results. Using scrap paper increases the risk of losing the results as well as transcription errors. The nurse may receive results by telephone, and while electronic transfer to the client's medical record is appropriate, the nurse can also accept the telephone results if the laboratory has called the results to the nursery. Sending client information via e-mail is unacceptable due to potential security and privacy issues.

CN: Safety and infection control; CL: Apply

75. 3. Hemolytic disease of the newborn is associated with Rh problems. Hemolytic disease of the newborn occurs most commonly when the mother is Rh negative and the infant is Rh positive. About 13% of Caucasians, 7% to 8% of people of African descent, and 1% of people of Asian descent are Rh negative. Rh-positive cells enter the mother's Rh-negative bloodstream, and antibodies to the Rh-positive cells are produced. In a subsequent pregnancy, the antibodies cross the placenta to the Rh-positive fetus and begin the destruction of Rh-positive cells through hemolysis. This results in severe fetal anemia.

CN: Physiological adaptation; CL: Apply

76. 3. The problem of Rh sensitivity arises when the mother's blood develops antibodies after fetal red blood cells enter the maternal circulation. In cases of Rh sensitivity, this usually does not occur until after the first pregnancy. Hence, hemolytic disease of the newborn is rare in a primiparous client. A mismatched blood transfusion in the past or an unrecognized

spontaneous abortion could also result in hemolytic disease because the transfusion or abortion would have the same effects on the client. The statement about the other baby having a different father may be true. However, if both fathers were Rh positive, then sensitization could occur. Most women do not have immunity against the antibodies formed when Rh-positive cells enter the mother's bloodstream. Antibodies are not neutralized by the mother's system.

CN: Reduction of risk potential; CL: Evaluate

77. 2. The Rh-sensitized neonate generally does not have problems related to polycythemia. Therefore, the client needs additional teaching. In general, moderate-to-severe Rh sensitization can cause anemia, enlarged spleen, and cardiac decompensation. Cardiac decompensation (as in heart failure) occurs because of severe anemia. Anemia is caused by the destruction of red blood cells by antibodies as the severity of hemolytic disease of the neonate increases. Splenic enlargement is caused by the excessive destruction of fetal red blood cells.

CN: Physiological adaptation; CL: Evaluate

78. 3. A direct Coombs test is done on umbilical cord blood to detect antibodies coating the neonate's red blood cells. Hematocrit is used to detect anemia. A direct Coombs does not measure bilirubin but may help explain the underlying cause of increased bilirubin levels. Antigens on the neonate's red blood cells are proteins that help determine the neonate's blood type.

CN: Reduction of risk potential; CL: Apply

79. 3. An exchange transfusion is done to reduce the blood concentration of bilirubin and correct the anemia. The exchange transfusion does not replenish the white blood cells or restore the fluid and electrolyte balance. The neonate's Rh-positive blood is replaced by Rh-negative blood.

CN: Reduction of risk potential; CL: Apply

80. 2. The organ most susceptible to damage from uncontrolled hemolytic disease is the brain. Bilirubin levels increase as the red blood cells are destroyed. Bilirubin crosses the blood-brain barrier and damages the cells of the central nervous system. This condition, called kernicterus, is potentially

fatal. Although the kidneys, lungs, and liver may be affected by increased bilirubin levels, the brain will sustain the most life-threatening injury.

CN: Reduction of risk potential; CL: Apply

81. 1,4. A blood glucose reading at or below 30 mg/dL (1.7 mmol/L) within 2 hours of birth and irregular respirations, tremors, and hypothermia are indicative of hypoglycemia. Blood glucose should be 45 mg/dL (2.5 mmol/L) by 24 hours of age. Internal fetal monitors detect the strength of contractions and the fetal heart rate. An infant of an insulin-dependent mother and a large-for-gestational-age infant are at greater risk of developing hypoglycemia and need to be observed carefully, but these findings are not definitive for the diagnosis of hypoglycemia.

CN: Physiological adaptation; CL: Analyze

82. 2. Glucose crosses the placenta, but insulin does not. Hence, a high maternal blood glucose level causes a high fetal blood glucose level. This causes the fetal pancreas to secrete more insulin. At birth, the neonate loses the maternal glucose source but continues to produce much insulin, which commonly causes a drop in blood glucose levels (hypoglycemia), usually at 30 to 60 minutes postpartum. Most neonates do not develop hypoglycemia if their mothers are not insulin dependent unless they are preterm. Therefore, hypoglycemia is not a normal response as the neonate transitions to extrauterine life.

CN: Reduction of risk potential; CL: Analyze

83. 1. Infants born to mothers with diabetes tend to be larger than average, and this neonate weighs 10 lb, 1 oz (4,564 g). The most common fractures are those of the clavicle and long bones, such as the femur. In a neonate, the skull bones are not fused and move to allow for vaginal birth, so skull fracture is rarely seen. Wrist and rib cages are rarely fractured.

CN: Reduction of risk potential; CL: Apply

84. 1. This neonate has a mother with diabetes who tends to have higher calcium levels, which can cause secondary hypoparathyroidism in their neonates. This lack of calcium may be the cause of the tremors and jitteriness of this neonate, and a serum calcium level should be obtained. Other factors

contributing to hypocalcemia in neonates include hypophosphatemia from tissue metabolism, vitamin D antagonism from increased cortisol levels, and decreased serum magnesium levels. Beginning a glucose IV based on a normal infant glucose level would have no benefit. Rechecking the neonate's temperature is a precaution that can be taken to assure that it is within normal limits but is not the action to take first. Refeeding the infant who has a normal newborn blood glucose level is not appropriate.

CN: Management of care; CL: Synthesize

85. 4. Hypoglycemia is caused by the rapid depletion of glucose stores. In addition, neonates born to class women with insulin-dependent diabetes are about seven times more likely to suffer from respiratory distress syndrome than neonates born to nondiabetic women. This neonate should be closely monitored for symptoms of hypoglycemia and respiratory distress. Neonates of diabetic mothers commonly have polycythemia, not anemia. Anemia and hemolytic disease are associated with erythroblastosis fetalis. Persistent pulmonary hypertension is associated with meconium aspiration syndrome.

CN: Reduction of risk potential; CL: Apply

86. 2. Manifestations of opiate withdrawal in the neonate include an increased central nervous system irritability, such as a shrill, high-pitched cry, gastrointestinal symptoms, and metabolic, vasomotor, and respiratory disturbances. These signs usually appear within 72 hours and persist for several days. These neonates are difficult to console, have poor feeding behaviors, and have diarrhea. Bradycardia is associated with preterm neonates. Sluggishness and lethargy are associated with neonates whose mothers received analgesia shortly before birth. Hypocalcemia occurs most commonly in infants of mothers with diabetes, premature infants, and low-birth weight infants.

CN: Reduction of risk potential; CL: Analyze

87. 3. Neonates experiencing opiate withdrawal have gastrointestinal problems similar to those of adults withdrawing from opiates. The neonates exhibit poor sucking, vomiting, drooling, diarrhea, regurgitation, and anorexia. In addition, they are difficult to console and difficult to feed. Because of these problems, the neonate withdrawing from opiates needs to be

monitored carefully to prevent dehydration. Neonates with opiate exposure experience hypertonia, not hypotonia, due to increased central nervous system irritability. Diarrhea, not constipation, is seen in these neonates. Abdominal distention is associated with necrotizing enterocolitis, not opiate withdrawal.

CN: Reduction of risk potential; CL: Evaluate

88. 1. A neonate undergoing cocaine withdrawal is irritable, often restless, difficult to console, and often in need of increased activity. It is commonly helpful to swaddle the neonate tightly with a blanket, offer a pacifier, and cuddle and rock the neonate. Offering extra nourishment is not advised because overfeeding tends to increase gastrointestinal problems such as vomiting, regurgitation, and diarrhea. Environmental stimuli such as bright lights and loud noises should be kept to a minimum to decrease agitation. Minimizing touching of the neonate to only when he or she is crying will not aid the bonding process between mother and neonate. Frequent holding and touching are permissible.

CN: Reduction of risk potential; CL: Synthesize

89. 4. New recommendations state that virologic diagnostic testing at birth should be considered for infants at high risk of HIV infection, but it may take several months before an accurate diagnosis can be made. New guidelines suggest that infants should be tested at 2 to 3 weeks, 1 to 2 months, and again 4 to 6 months. It is estimated that 15% to 30% of all HIV-positive mothers without treatment will give birth to HIV-positive infants. With appropriate drug intervention to the mother during pregnancy, 95% of these neonates can be born unaffected. An enlarged liver at birth is associated with erythroblastosis fetalis, not HIV infection. Virologic testing, such as deoxyribonucleic acid polymerase chain reaction, viral culture, or ribonucleic acid plasma assay, can diagnose HIV infection by 6 months of age and commonly in the first month.

CN: Reduction of risk potential; CL: Apply

90. 4. Breast milk has been found to contain the retrovirus HIV. In general, mothers are discouraged from breast-feeding if they are HIV positive because of the risk of possible transmission of the virus if the neonate is HIV

negative. Breast milk does contain some immunoglobulins, but it does not protect the neonate from HIV infection.

CN: Health promotion and maintenance; CL: Create

91. 1. Newborns are typically bathed 2 to 4 hours after birth when their temperatures have had time to stabilize, but early/immediate bathing is recommended for the infants of HIV-positive mothers to decrease blood exposure. Placing the neonate under the radiant warmer for the vitamin K injection is not necessary unless the neonate's temperature is subnormal. Washing the injection site with povidone-iodine is not recommended and may increase the risk for possible allergy to iodine preparations. The first dose of zidovudine is given when the newborn is 6 to 12 hours old, but vitamin K is recommended to be given within an hour of birth to be most effective. Therefore, the vitamin K should not be delayed.

CN: Safety and infection control; CL: Synthesize

92. 3. Symptoms of infection in a neonate include subtle behavioral changes, such as lethargy and irritability, and color changes such as pallor or cyanosis. Other symptoms include temperature instability, poor feeding, gastrointestinal disorders, hyperbilirubinemia, and apnea. Leukocytosis, an elevated white blood cell count possibly as high as 30,000 cells/mm³ ($30 \times 10^9/L$) or more, may be normal during the first 24 hours. An apical heart rate of 132 bpm is normal. Warm, moist skin is not a typical sign of infection in neonates. Typically, temperature instability is common. The neonate's temperature is low, and the skin is cool and dry.

CN: Health promotion and maintenance; CL: Analyze

93. 3. The parents of a neonate with an infection should be allowed to participate in daily care as long as they use good handwashing technique. This includes touching and holding the neonate. It is not necessary for parents to wearing protective gear new the isolette. Restricting parental visits has not been shown to have any effect on the infection rate and may have detrimental effects on the neonate's psychological development. Normally, the neonate does not need to be isolated. The baby will not spread sepsis via respiratory droplets to parents so is not necessary for the parents to wear a mask.

CN: Safety and infection control; CL: Apply

94. 3. On the initial visit, the parents may be shocked, fearful, and anxious. Nursing care should include spending time with the parents to allow them to express their emotions. The nurse should initially emphasize the neonate's normal characteristics. After the parents have had sufficient time to adjust to the neonate's special needs, surgical interventions can be discussed. Telling the parents that this is not a life-threatening defect or that everything will be all right after the surgery is not helpful. Doing so discounts their feelings. Reassuring the parents about the success rate of the surgery can be done once the parents have had time to adjust to the neonate and express their emotions.

CN: Psychosocial integrity; CL: Synthesize

95. 1. It is not necessary to clean the mouth of an infant with an unrepaired cleft palate after each feeding. The neonate needs to be fed in an upright position to prevent aspiration. The neonate with a cleft lip and palate commonly swallows large amounts of air during feeding. Therefore, the neonate needs to be burped frequently to help eliminate the air and decrease the risk for regurgitation. The neonate with a cleft lip and palate should be fed with a special soft nipple that fills the cleft and facilitates sucking.

CN: Reduction of risk potential; CL: Evaluate

96. 4. The long-term prognosis for neonates with FAS is poor. Symptoms of withdrawal include tremors, sleeplessness, seizures, abdominal distention, hyperactivity, and inconsolable crying. Symptoms of withdrawal commonly occur within 6 to 12 hours or, at the latest, within the first 3 days of life. The neonate with FAS is usually growth deficient at birth. Most neonates with FAS are mildly to severely mentally handicapped. The facial deformities, such as short palpebral fissures, epicanthal folds, broad nasal bridge, flattened midface, and short, upturned nose, are not easily corrected with plastic surgery.

CN: Reduction of risk potential; CL: Create

97. 3. Central nervous system disorders are common in neonates with FAS. Speech and language disorders and hyperactivity are common manifestations of central nervous system dysfunction. Mild-to-severe mental retardation and feeding problems also are common. Delayed growth and development is expected. These neonates feed poorly and commonly have

persistent vomiting until age 6 to 7 months. These neonates do not have a 70% mortality rate, and there is no treatment for FAS.

CN: Reduction of risk potential; CL: Apply

98. 4. Changes seen in the facial features of newborns with fetal alcohol syndrome remain that way. These include epicanthal folds, whorls, irregular hair, cleft lip or palate, small teeth, and lack of philtrum. Newborns with fetal alcohol syndrome are usually difficult to calm and frequently cry for long periods of time. Parents do need assistance with caring for themselves and their infants, particularly with continued alcohol use. A supportive family or support systems are essential. The problems seen with this newborn do not go away and remain with the infant throughout life and are compounded when the child begins to develop mentally.

CN: Health promotion and maintenance; CL: Evaluate

99. 1. The parents need to know that the neonate will be kept on NPO status and will receive intravenous therapy before surgery. After surgery, feeding will depend on the neonate's condition. Total parenteral nutrition may be prescribed after surgery, but not before. Breast-feeding may be started after surgery if the neonate's condition is stable. The mother can pump the breasts until that time.

CN: Reduction of risk potential; CL: Apply

100. 1,2,4. The major goals for the neonate include preventing hypothermia, maintaining fluid and electrolyte balance, and preventing infection. Pain medication will be needed after surgery but is not typically needed before the procedure. In many cases, surgery is done very soon after birth. So while developmental care is important, it should be addressed after the closure of the abdominal wall defect.

CN: Reduction of risk potential; CL: Create

101. 2. The physical appearance of the anomaly and the life-threatening nature of the disorder may result in shock to the parents. The parents may hesitate to form a bond with the neonate because of the guarded prognosis. Denial would be evidenced if the parents acted as if nothing were wrong. Bargaining would be evidenced by parental statements involving "if-then"

phrasing, such as, “If the surgery is successful, I will go to church every Sunday.” Anger would be evidenced if the parents attempted to blame someone, such as healthcare personnel, for the neonate’s condition.

CN: Psychosocial integrity; CL: Analyze

102. 1. To prevent eye damage from phototherapy, the eyes must remain covered at all times while under the lights. The eye patches can be removed when the neonate is held out of the lights by the parents for feeding. Instead of a regular diaper, a “string” diaper or disposable face mask may be used to help contain loose stools, while allowing maximum skin exposure. Feeding formula or breast milk every 2 to 3 hours is recommended to prevent hypoglycemia and to encourage gastrointestinal motility. Because the phototherapy lights can overheat the neonate, the temperature should be checked by the axillary route every 2 to 4 hours.

CN: Reduction of risk potential; CL: Apply

103. 4. An absent Moro reflex, lethargy, opisthotonos, and seizures are symptoms of bilirubin encephalopathy, which, although rare, can be life-threatening. Bronze discoloration of the skin and maculopapular chest rash are normal and are caused by the phototherapy. They will disappear once the phototherapy is discontinued. A urine specific gravity of 1.001 to 1.020 is normal in term neonates.

CN: Reduction of risk potential; CL: Analyze

104. 2. Marked visible peristaltic waves in the abdomen and projectile vomiting are signs of pyloric stenosis. If the condition progresses without surgical intervention, the neonate will become dehydrated and develop metabolic alkalosis. Signs of esophageal atresia include coughing and regurgitation with feedings. Diaphragmatic hernia, a life-threatening event in which the abdominal contents herniate into the thoracic cavity, may be evidenced by breath sounds being heard over the abdomen and significant respiratory distress with cyanosis. Signs of hiatal hernia include vomiting, failure to thrive, and short periods of apnea.

CN: Reduction of risk potential; CL: Analyze

105. 3. With a patent ductus arteriosus, a cardiac defect marked by a

failure of the patent ductus arteriosus to close completely at birth, blood from the aorta flows into the pulmonary arteries to be reoxygenated in the lungs and returned to the left atrium and ventricle. The effect of this altered circulation includes increased workload on the left side of the heart and increased pulmonary vascular congestion. Term infants are commonly asymptomatic, but a loud, machinery-like murmur may be heard throughout systole and diastole. This murmur may be accompanied by a suprasternal thrill, and the heart may be enlarged. Decreased cardiac output with faint peripheral pulses, poor peripheral perfusion, feeding difficulties, and severe congestive heart failure are symptoms associated with severe aortic stenosis. With this defect, the aortic valve is thickened and rigid, leading to decreased cardiac output and reduced myocardial blood flow. Profound cyanosis over most of the body, fatigue on exertion, feeding difficulties, and chronic hypoxemia are associated with tetralogy of Fallot. With this defect, malalignment of the ventricular system results in nonrestricted ventral septal defects, pulmonic stenosis, overriding of the aorta, and hypertrophy of the left ventricle. The heart appears boot shaped. A harsh systolic murmur with a palpable thrill is associated with truncus arteriosus. It is marked by incomplete division of the great vessel. This is caused by a ventral septal defect. Bounding pulses and a widening pulse pressure may also be present.

CN: Reduction of risk potential; CL: Analyze

106. 1. Coarctation of the aorta accounts for 5% to 7% of congenital heart disease. There is localized constriction of the aorta, at or near the insertion site of the ductus arteriosus, that increases afterload and decreases cardiac output. The infant with coarctation of the aorta presents with symptoms of poor lower body perfusion, weak lower extremity pulses, and congestive heart failure, including respiratory distress. The child with a partial atrioventricular septal defect may be asymptomatic at birth. The symptoms in a child with a complete defect depend on the pulmonary artery pressure. The child with pulmonary atresia has profound (complete) cyanosis. Transposition of the great arteries is associated with complete cyanosis during the first few hours of life.

CN: Reduction of risk potential; CL: Analyze

107. 4. The normal pulse rate in a neonate is 120 to 160 bpm. Therefore, a

femoral pulse rate of 90 bpm is too low. Diminished peripheral pulses, coolness and mottling of the extremities, delayed capillary refill, hypotension, and decreased urine output are indicative of low cardiac output and poor perfusion. The neonate may be experiencing a complication of the surgery, such as blood loss or leaking of fluid into the interstitial space. The surgeon should be notified immediately to correct the diminished pulse, through either medications or transfusions. An oxygen saturation between 85% and 100% is considered normal. The surgeon does not need to be notified unless the oxygen saturation falls below 85%. Pale pink extremities are considered a normal finding. If mottling or cyanosis develops, the surgeon should be notified immediately. Warm, dry skin is also a normal finding. If the skin becomes cool or appears cyanotic, the surgeon should be notified.

CN: Reduction of risk potential; CL: Synthesize

108. 3. The neonate is experiencing quiet tachypnea with central cyanosis, which is a sign of possible congenital heart disease, so notifying the **HCP**  is the correct answer. The baby is showing no signs of increased work of breathing, except increased respiratory rate. Breath sounds are clear; therefore, suctioning is not necessary and may cause further distress due to trauma to the nasal passage. Changing the neonate's position would have no impact on the cyanosis. Encouraging the baby to cry would increase the distress by decreasing oxygen consumption.

CN: Physiological adaptation; CL: Analyze

109. 4. The next nursing action in this situation would be to assess the blood pressure in all four extremities and compare the findings. A difference of 15 mm Hg in the systolic blood pressure between the arms and legs is an indication of a narrowed aorta. This could be an emergency, and the **HCP**  needs to be notified as soon as the blood pressure data have been collected. Generally, prescribing an HCP consult is not a nursing function. Placing the neonate in reverse Trendelenburg will only decrease the perfusion to the lower extremities.

CN: Physiological adaptation; CL: Analyze

110. 4. Further assessment for signs of distress is necessary. At 4 hours of

age, a transient murmur may be heard as the fetal shunts are closing. This is a normal finding. If no other distress is noted, the **HCP** 📖 does not need to be called. Result can be noted on the **medical record**. Further assessment is needed to know if continuing routine care and feeding are appropriate and safe for the neonate.

🔑 CN: Physiological adaptation; CL: Analyze

111.

Subcostal retractions are noted under the rib cage. Intercostal retractions are noted between the ribs. Suprasternal retractions are found above the sternum, and the substernal retractions are found below the sternum.

🔑 CN: Physiological adaptation; CL: Apply

112. 2. Parents who have experienced perinatal loss have described statements such as “I am sorry for your loss” as helpful. All other statements are not helpful. A nurse can empathize, but may not know what clients are feeling unless they have been given an opportunity to express their emotions. Stating that time heals is a cliché. Suggesting the client can have another child makes a false assumption that one child can replace another. Also the

client may not have the ability to have another child.

 CN: Psychosocial integrity; CL: Apply

Managing Care, Quality, and Safety of Neonatal Clients

113. 1. The preterm infant is at greatest risk for developing RDS as the lungs are immature and unable to produce adequate surfactant to reduce the surface tension in the lungs and promote the stability of the alveoli. The neonate born at 42 weeks' gestation is at greater risk of having meconium-stained amniotic fluid and developing meconium aspiration syndrome. The neonate born by cesarean section is at greater risk of fluid retention in the lungs as the lungs are not compressed during the birth process as they are in a vaginal birth. Generally, these infants are able to overcome this situation with adequate crying. Apneic episodes in infants may be related to several conditions, including hypothermia, sepsis, and hypoglycemia, or a result of a rapid increase in the infant's temperature.

 CN: Management of care; CL: Analyze

114. 3. The nurse should make rounds and first assess the neonate with the respiratory rate of 62. The respiratory rate is out of the normal range and needs reevaluation. The nurse should next assess the newborn with a borderline low temperature to determine if his body temperature is increasing. The newborn who is LGA still has 15 minutes before being due for the feeding, and much can be accomplished by the nurse in that time. A 36-week newborn weighing 5 lb (2,270 g) will need to be fed on time to maintain the blood glucose level.

 CN: Management of care; CL: Synthesize

115. 3. A temperature of 96.6°F (35.9°C) and jitteriness are signs of hypoglycemia in the newborn. The nurse must first obtain a heel stick blood sample for blood glucose. Breast-feeding, preferably skin-to-skin, should be initiated immediately following the heel stick puncture to treat the suspected hypoglycemia. The **HCP**  can be notified once the blood glucose value is known and the baby is successfully breast-feeding. Normal newborn temperature ranges from 97.7°F (36.5°C) to 99.1°F (37.3°C). A temperature of 96.6°F (35.9°C) is low, another sign of hypoglycemia; however, breast-

feeding takes precedence over the radiant heater. Also, breast-feeding via skin-to-skin contact has been found as the most effective way to maintain a newborn's temperature.

CN: Management of care; CL: Synthesize

116. 2. The mother demonstrates signs of full bladder and vaginal bleeding and requires assistance with bladder emptying and uterine massage to assess the origination of the bleeding. The newborn requires further assessment because turning dusky when quiet and respiration rate of 70 breaths/min indicate the beginning signs of respiratory distress and requires prompt intervention. All other mothers are recovering normally. While bilateral crackles in a newborn could indicate excessive fluid, a pink color indicates the infant is maintaining oxygenation. Normal respiration is 30 to 60 breaths/min. While a respiratory rate of 67 is slightly elevated, the baby is not demonstrating any other signs of respiratory distress. The newborn with acrocyanosis (bluish hands and feet) is a normal newborn finding and shows the ability to maintain oxygenation. Respirations of 70 breaths/min and intermittent expiratory grunt would indicate close observation but does not require immediate intervention if the infant is pink. The last newborn is maintaining oxygenation, with respirations just slightly above normal. Periodic breathing, featuring pauses in breathing of less than 15 seconds, is a normal newborn finding.

CN: Management of care; CL: Synthesize

117. 2,3,4,5. A hospital-specific security system is the standard of care to prevent neonatal abduction. The bulb syringe should be visible and easily accessible to both the mother and the nurse in case of choking. Someone should remain in the room who is able to safely care for the infant. This may be the mother or a family member if the mother is physically not able to care for the infant. The infant should be lying on the back or side, rather than the abdomen to prevent sudden infant death syndrome (“back to sleep”). Infant falls from a mother's bed are a serious safety problem. The infant should be in the mother's arms or in the crib rather than lying on a bed, even with the side rails up, as an infant can slip through the rails. A sleeping mother is not aware of the status of the infant who can easily fall out of her arms; the infant can be in the mother's arms only if she is awake.

CN: Safety and infection control; CL: Evaluate

118. 2. The blood glucose of 25 (1.38 mmol/L) is the most critical. Glucose is the only fuel that the brain can use. It is important to protect the central nervous system, and levels less than 30 (1.7 mmol/L) in the first 6 hours of life of a neonate indicate hypoglycemia. Occasional grunting at ½ hour of age may be normal transitioning to extrauterine life. A temperature of 97.4°F (36.4°C) is only slightly low for a neonate at this age. Ninety-five percent of all neonates will void at least once in the first 24 hours. This is not unusual at this age.

CN: Management of care; CL: Analyze

119. 4,1,3,2. Based on the report given by the preceding nurse, the nurse should plan to prioritize all clients and first make rounds on the client needing the highest level of nursing care. The nurse can then make rounds on all other clients. The nurse can then check for new prescriptions and, finally, inspect the room in which the next client will be admitted to be sure all of the equipment is available.

CN: Management of care; CL: Synthesize

120. 2,4,5. The role of the **UAP** allows this member of the healthcare team to take vital signs on clients, record feedings, and voids and stools of infants according to hospital guidelines. The newborn assessment is completed by a licensed care provider as is the tube feeding. Bathing of the newborn is within the scope of practice for the UAP, but the initial assessment of patency of the gastrointestinal tract, which is initiated by the first feeding, is within the scope of licensed care providers. If there is a trachea esophageal fistula, this is the time when it may become evident.

CN: Management of care; CL: Apply

- Health Promotion of the Adolescent and Family
- Common Childhood and Adolescent Health Problems
- Managing Care, Quality, and Safety of Children
- Answers, Rationales, and Test-Taking Strategies

Health Promotion of the Infant and Family

1. After reading the vaccine information sheets, the parent of a 2-month-old infant is hesitant to consent to the recommended vaccinations. The nurse should **first** ask the parent:

- ☐ **1.** “Did you know that vaccinations are required by law for school entry?”
- ☐ **2.** “What concerns do you have about vaccinations?”
- ☐ **3.** “Would you prefer that fewer vaccines are given at a time?”
- ☐ **4.** “Can you please sign this vaccine waiver form?”

2. Which is appropriate language development for an 8-month-old? The child should be:

- ☐ 1. saying “dada” and “mama” specifically (“dada” to father and “mama” to mother).
- ☐ 2. saying three other words besides “mama” and “dada.”
- ☐ 3. saying “dada” and “mama” nonspecifically.
- ☐ 4. saying “ball” when parents point to a ball.

3. The nurse should refer the parents of an 8-month-old child to a healthcare provider (HCP) if the child is unable to:

- ☐ 1. stand momentarily without holding onto furniture.
- ☐ 2. stand unsupported well for long periods of time.
- ☐ 3. stoop to recover an object.
- ☐ 4. sit without support for long periods of time.

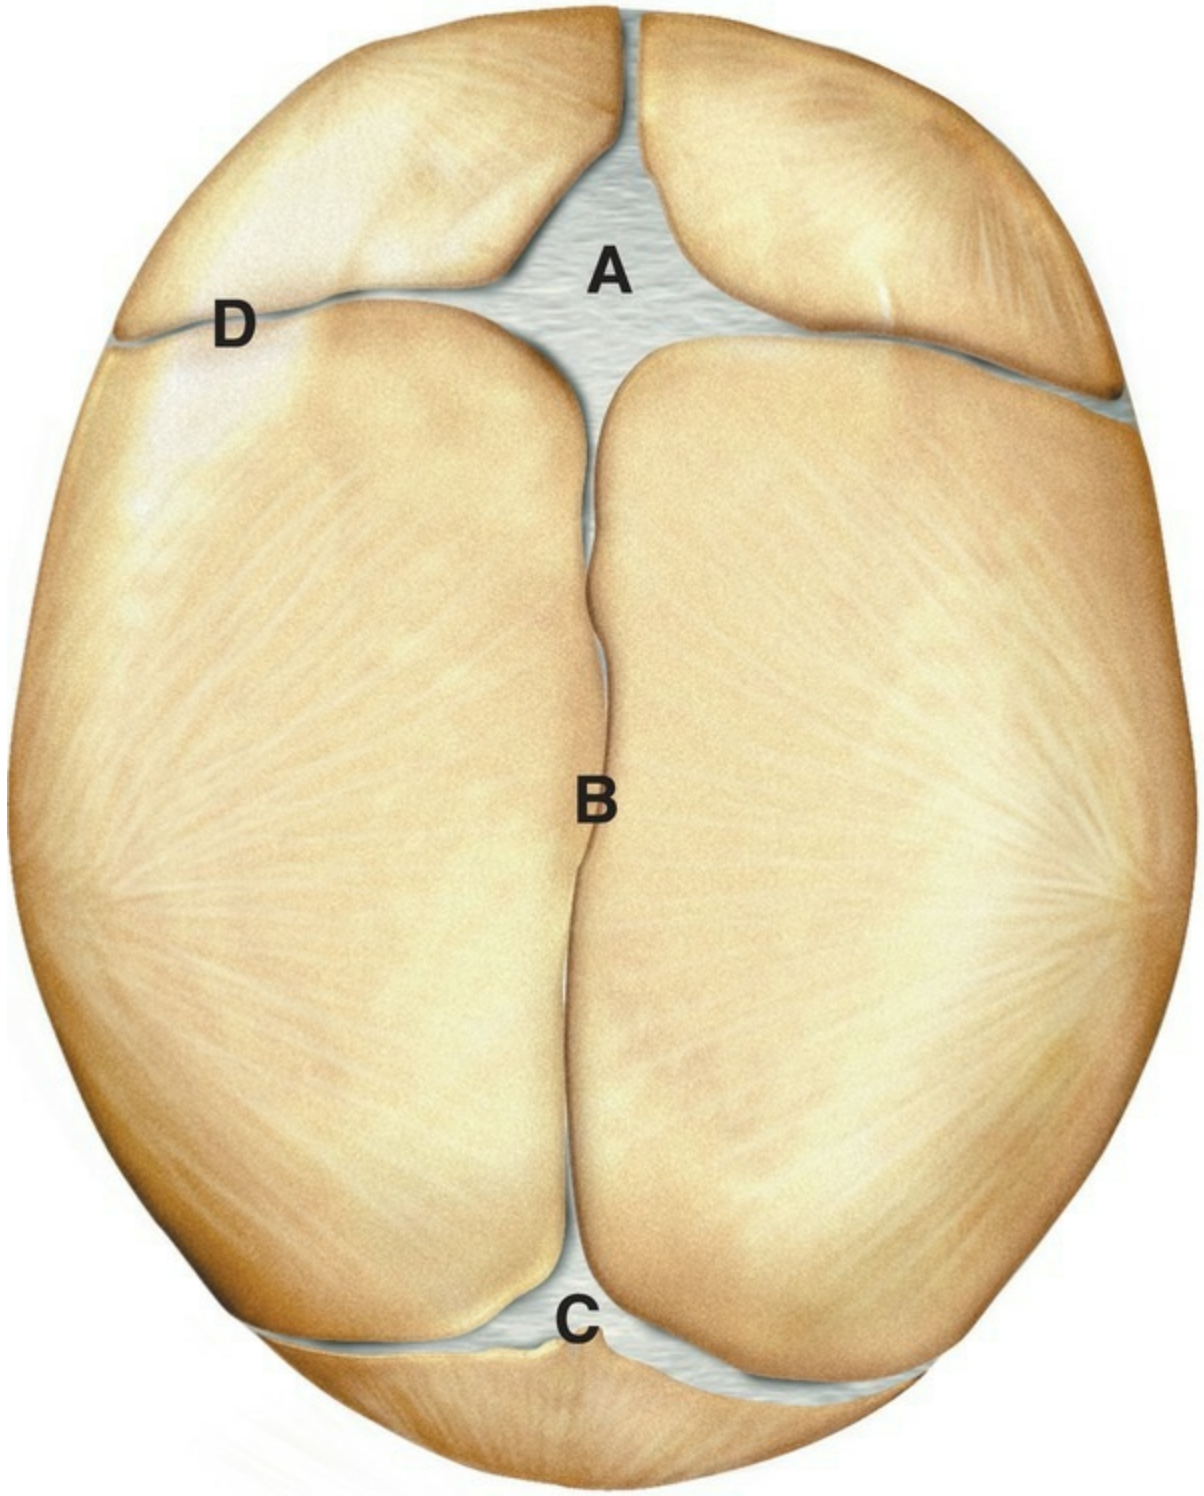

4. The nurse is teaching the parents of an 8-month-old about what the child should eat. The nurse should include which information points in the teaching plan?

- ☐ 1. Vegetables should be introduced before fruits.
- ☐ 2. Solid foods should not be introduced until the infant is 10 months old.
- ☐ 3. Iron-fortified cereals should not be introduced until the infant is 8 months old.
- ☐ 4. The infant’s diet can be changed from formula to whole milk when the infant is 12 months old.

5. A 10-month-old looks for objects that have been removed from his view. The nurse should instruct the parents that:

- ☐ 1. neuromuscular development enables the child to reach out and grasp objects.
- ☐ 2. the child’s curiosity has increased.
- ☐ 3. the child understands the permanence of objects even though the child cannot see them.
- ☐ 4. the child is now able to transfer objects from hand to hand.

6. Which structure should be closed by the time the child is 2 months old?

- ☐ 1. A
- ☐ 2. B
- ☐ 3. C
- ☐ 4. D

7. Which statement by a parent reflects the need for further teaching regarding car seat safety?

- ☐ 1. "My baby should stay in a rear-facing car seat until he is 1 year old."
- ☐ 2. "I should check my old car seat's expiration date before using it for this baby."
- ☐ 3. "My older child will need to stay in a booster seat until he is 4 feet 9 inches (144.8 cm)."
- ☐ 4. "My children should ride in the back seat until they are 13 years old."

8. The parents of a 3-week-old healthy newborn ask the nurse why their child is intermittently cross-eyed. The nurse's **best** response is:

- ☐ 1. "An eye patch may be necessary for 6 weeks to correct your child's vision."
- ☐ 2. "Your child will likely need an ophthalmology consult."
- ☐ 3. "It is normal to have eye-crossing in the newborn period."
- ☐ 4. "Surgery may be necessary to correct your child's vision."

9. A parent brings a 4-month-old to the clinic for a regular well visit and expresses concern that the infant is not developing appropriately. Which finding in the infant would indicate the need for further developmental screening?

- ☐ 1. has no interest in peekaboo games
- ☐ 2. does not turn front to back
- ☐ 3. does not babble
- ☐ 4. sits unsupported

10. The nurse assesses a 6-month-old for vaccination readiness. Which finding would **most** likely indicate the need to delay administering the diphtheria, tetanus, and acellular pertussis (DTaP) vaccine?

- ☐ 1. a family history of sudden infant death syndrome (SIDS)
- ☐ 2. a fever of 38.5°C (101.3°F) following the 4-month vaccinations
- ☐ 3. an acute bilateral ear infection
- ☐ 4. living with a family member who is immunosuppressed

11. The parents of a 9-month-old bring the infant to the clinic for a regular checkup. The infant has received no immunizations. Which vaccine if

prescribed would the nurse question?

- ☐ 1. diphtheria, tetanus, and acellular pertussis (DTaP)
- ☐ 2. Haemophilus influenzae type B (Hib)
- ☐ 3. measles, mumps, and rubella (MMR)
- ☐ 4. inactivated influenza (Flu)

12. To assess the development of a 1-month-old, the nurse asks the parent if the infant is able to:

- ☐ 1. smile and laugh out loud.
- ☐ 2. roll from back to side.
- ☐ 3. hold a rattle briefly.
- ☐ 4. lift head from prone position.

13. The parent of a 6-month-old reports starting 2% milk. The nurse should **first** ask the parent:

- ☐ 1. “Do you think your baby will be fine with this milk?”
- ☐ 2. “Is it possible for you to switch your baby to whole milk?”
- ☐ 3. “Can you tell me more about the reason you switched your baby to 2% milk?”
- ☐ 4. “You cannot switch to 2% milk right now. Did your pediatrician tell you to do this?”

14. The nurse notes that an infant stares at an object placed in his hand and takes it to his mouth, coos and gurgles when talked to, and sustains part of his own weight when held in a standing position. The nurse correctly interprets these findings as characteristic of an infant at which age?

- ☐ 1. 2 months
- ☐ 2. 4 months
- ☐ 3. 7 months
- ☐ 4. 9 months

15. An 8-month-old infant is seen in the well-child clinic for a routine checkup. The nurse should expect the infant to be able to do which tasks? Select all that apply.

- ☐ 1. say “mama” and “dada” with specific meaning

- ☐ 2. feed self with a spoon
- ☐ 3. play peekaboo
- ☐ 4. walk independently
- ☐ 5. stack two blocks
- ☐ 6. transfer object from hand to hand

16. The parent of a 9-month-old infant is concerned that the infant's front soft spot is still open. The nurse should tell the parent:

- ☐ 1. "I will measure your baby's head to see if it is a normal size."
- ☐ 2. "Your infant will need to be referred for more testing."
- ☐ 3. "You should contact your healthcare provider immediately."
- ☐ 4. "This is normal because this soft spot usually closes between 12 and 18 months."

17. The parent of a 9-month-old expressed concern that the baby "is developing slowly." The nurse is concerned about a developmental delay when finding the baby is unable to accomplish which skill?

- ☐ 1. vocalizing single syllables
- ☐ 2. standing alone
- ☐ 3. building a tower of two cubes
- ☐ 4. drinking from a cup with little spilling

18. Which infant **most** needs a developmental referral for a gross motor delay?

- ☐ 1. the 2-month-old who does not roll over
- ☐ 2. the 4-month-old who does not sit without support
- ☐ 3. the 6-month-old who does not crawl
- ☐ 4. the 9-month-old who does not stand holding on

19. Which intervention should the nurse employ to reduce trauma caused by vaccine administration to an infant?

- ☐ 1. Use a 5/8-inch (1.6-cm) needle.
- ☐ 2. Simultaneously administer vaccines at separate sites with a second nurse.
- ☐ 3. Aspirate to verify needle placement.

- ☐ 4. Breast-feed right before administering the vaccines.

Health Promotion of the Toddler and Family

20. An uncle is shopping for a toy to give his niece. He has no children of his own and asks his neighbor, a nurse, what would be the **most** appropriate toy to give a 15-month-old child. Which toy should the nurse recommend to facilitate learning and development?

- ☐ 1. a stuffed animal
- ☐ 2. a music box
- ☐ 3. a push-pull toy
- ☐ 4. a nursery mobile

21. A 2-year-old tells his parent he is afraid to go to sleep because “the monsters will get him.” The nurse should tell his parent to:

- ☐ 1. allow him to sleep with his parents in their bed whenever he is afraid.
- ☐ 2. increase his activity before he goes to bed so he eventually falls asleep from being tired.
- ☐ 3. read a story to him before bedtime, and allow him to have a cuddly animal or a blanket.
- ☐ 4. allow him to stay up an hour later with the family until he falls asleep.

22. A 2-year-old always puts his teddy bear at the head of his bed before he goes to sleep. The parents ask the nurse if this behavior is normal. The nurse should explain to the parents that toddlers use ritualistic patterns to:

- ☐ 1. establish a sense of identity.
- ☐ 2. establish control over adults in their environment.
- ☐ 3. establish sequenced patterns of learning behavior.
- ☐ 4. establish a sense of security.

23. Which development is necessary for toilet training readiness for a 2-year-old? Select all that apply.

- ☐ 1. adequate neuromuscular development for sphincter control
- ☐ 2. appropriate chronological age
- ☐ 3. ability to communicate the need to use the toilet
- ☐ 4. desire to please the parents

☐ 5. ability to play with other 2-year-olds

24. A parent of a toilet-trained 3-year-old expresses concern over her child's bed-wetting while hospitalized. The nurse should tell the parent:

- ☐ 1. "Your child was too immature to be toilet trained. In a few months your child should be old enough."
- ☐ 2. "Children are afraid in the hospital and frequently wet their bed."
- ☐ 3. "It is very common for children to regress when they are in the hospital."
- ☐ 4. "This is normal. Your child probably received too much fluid the night before."

25. The nurse is to obtain a urine specimen from a toddler hospitalized with a urinary tract infection. In what order should the nurse perform the following steps? Place in order from first to last. All options must be used.

1. Cleanse the genital area.

2. Apply gloves.

3. Offer fluids.

4. Apply collection bag.

26. A parent brings in an 18-month-old to the clinic because the child "eats ashes, crayons, and paper." Which information about the toddler should

the nurse assess **first**?

- ☐ 1. evidence of eruption of large teeth
- ☐ 2. amount of attention from the parent
- ☐ 3. any changes in the home environment
- ☐ 4. intake of a soft, low-roughage diet

27. When assessing a 2-year-old child at the clinic for a routine checkup, which skill should the nurse expect the child to be able to perform?

- ☐ 1. ride a tricycle
- ☐ 2. tie his or her shoelaces
- ☐ 3. kick a ball forward
- ☐ 4. use blunt scissors

28. A 2-year-old child brought to the clinic by her parents is uncooperative when the nurse tries to look in her ears. What should the nurse try **first**?

- ☐ 1. Ask another nurse to assist.
- ☐ 2. Allow a parent to assist.
- ☐ 3. Wait until the child calms down.
- ☐ 4. Restrain the child's arms.

29. When observing the parent instilling prescribed ear drops prescribed twice a day for a 2-year-old, the nurse decides that the teaching about positioning of the pinna for instillation of the drops is effective when the parent pulls the toddler's pinna in which direction?

- ☐ 1. up and forward
- ☐ 2. up and backward
- ☐ 3. down and forward
- ☐ 4. down and backward

30. The mother asks the nurse for advice about discipline for her 18-month-old. Which discipline strategy should the nurse suggest that the mother use?

- ☐ 1. reprimand
- ☐ 2. spanking
- ☐ 3. reasoning

- ☐ 4. time-out

31. When assessing for pain in a toddler, which method should be the **most** appropriate?

- ☐ 1. Ask the child about the pain.
- ☐ 2. Observe the child for restlessness.
- ☐ 3. Use a numeric rating pain scale.
- ☐ 4. Assess for changes in vital signs.

32. Which amount of daily milk intake should the nurse include in the plan of care for a 15-month-old?

- ☐ 1. $\frac{1}{2}$ to 1 cup (125 to 250 mL)
- ☐ 2. 2 to 3 cups (500 to 750 mL)
- ☐ 3. 3 to 4 cups (750 to 1,000 mL)
- ☐ 4. 4 to 5 cups (1,000 to 1,250 mL)

Health Promotion of the Preschooler and Family

33. The nurse teaches the parents of a 4-year-old diagnosed with iron deficiency anemia about potential side effects of taking an iron supplement. The nurse knows more teaching is required when the parents state a side effect of taking an iron supplement is:

- ☐ 1. teeth staining.
- ☐ 2. black stools.
- ☐ 3. anorexia.
- ☐ 4. dark urine.

34. The parent of a 4-year-old expresses concern that the child may be hyperactive. The parent describes the child as always in motion, constantly dropping and spilling things. Which action would be appropriate at this time?

- ☐ 1. Determine whether there have been any changes at home.
- ☐ 2. Explain that this is not unusual behavior.
- ☐ 3. Explore the possibility that the child is being abused.
- ☐ 4. Suggest that the child be seen by a pediatric neurologist.

35. The parent of a preschooler reports that the child creates a scene every

night at bedtime. What is the **best** course of action?

- ☐ 1. Allow the child to stay up later one or two nights a week.
- ☐ 2. Establish a set bedtime and follow a routine.
- ☐ 3. Encourage active play before bedtime.
- ☐ 4. Give the child a cookie if bedtime is pleasant.

36. The parents of a preschooler ask the nurse how to handle their child's temper tantrums. Which technique should the nurse include in the teaching plan? Select all that apply.

- ☐ 1. putting the child in "time-out"
- ☐ 2. ignoring the child
- ☐ 3. putting the child to bed
- ☐ 4. spanking the child
- ☐ 5. trying to reason with the child

37. After teaching a group of parents of preschoolers attending a well-child clinic about oral hygiene and tooth brushing, the nurse determines that the teaching has been successful when the parents state that children can begin to brush their teeth without help at which age?

- ☐ 1. 3 years
- ☐ 2. 5 years
- ☐ 3. 7 years
- ☐ 4. 9 years

38. After having a blood sample drawn, a 5-year-old child insists that the site be covered with a bandage. When the parent tries to remove the bandage before leaving the office, the child screams that all the blood will come out. The nurse encourages the parent to leave the bandage in place and tells the parent that the child:

- ☐ 1. fears another procedure.
- ☐ 2. does not understand body integrity.
- ☐ 3. is expressing pain.
- ☐ 4. is attempting to regain control.

39. The family of a 5-year-old, only child has just moved to a rural setting. At the well-child visit, the father expresses concern that his child seems prone

to minor accidents such as skinning his elbow and knees or falling off his scooter. The nurse tells the father:

- ☐ 1. "Only children use accidents as a way to seek parental attention."
- ☐ 2. "Children who live in the suburbs typically have more accidents."
- ☐ 3. "Children frequently have more accidents when families experience change."
- ☐ 4. "We see a relationship between accidents and parental education."

40. When developing the teaching plan about illness for the parent of a preschooler, which information should the nurse include about how a preschooler perceives illness?

- ☐ 1. a necessary part of life
- ☐ 2. a test of self-worth
- ☐ 3. a punishment for wrongdoing
- ☐ 4. the will of God

Health Promotion of the School-Age Child and Family

41. To interpret the results of blood pressure screenings in children over 3 years of age, the nurse compares the results to percentiles for systolic and diastolic blood pressure based on what factors? Select all that apply.

- ☐ 1. age
- ☐ 2. body mass index (BMI)
- ☐ 3. gender
- ☐ 4. height
- ☐ 5. occipital frontal circumference (OFC)
- ☐ 6. weight

42. A nurse is assessing the growth and development of a 10-year-old. What is the expected behavior of this child?

- ☐ 1. enjoys physical demonstrations of affection
- ☐ 2. is selfish and insensitive to the welfare of others
- ☐ 3. is uncooperative in play and school
- ☐ 4. has a strong sense of justice and fair play

43. To assess a 9-year-old's social development, the nurse asks the parent if the child:

- ☐ 1. thinks independently.
- ☐ 2. is able to organize and plan.
- ☐ 3. has a best friend.
- ☐ 4. enjoys active play.

44. A 10-year-old child proudly tells the nurse that brushing and flossing her teeth is her responsibility. How does the nurse interpret the statement?

- ☐ 1. She is too young to be given this responsibility.
- ☐ 2. She is most likely capable of this responsibility.
- ☐ 3. She should have assumed this responsibility much sooner.
- ☐ 4. She is probably just exaggerating the responsibility.

45. The parent tells the nurse that an 8-year-old child is continually telling jokes and riddles to the point of driving the other family members crazy. The nurse should explain this behavior is a sign of:

- ☐ 1. inadequate parental attention.
- ☐ 2. mastery of language ambiguities.
- ☐ 3. inappropriate peer influence.
- ☐ 4. excessive television watching.

46. The parent asks the nurse about a 9-year-old child's apparent need for between-meal snacks, especially after school. When developing a sound nutritional plan for the child with the mother, the nurse should advise the parent that:

- ☐ 1. the child does not need to eat between-meal snacks.
- ☐ 2. the child should eat the snacks the mother thinks are appropriate.
- ☐ 3. the child should help with preparing his or her own snacks.
- ☐ 4. the child will instinctively select nutritional snacks.

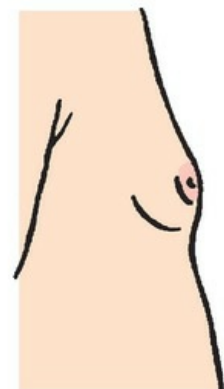

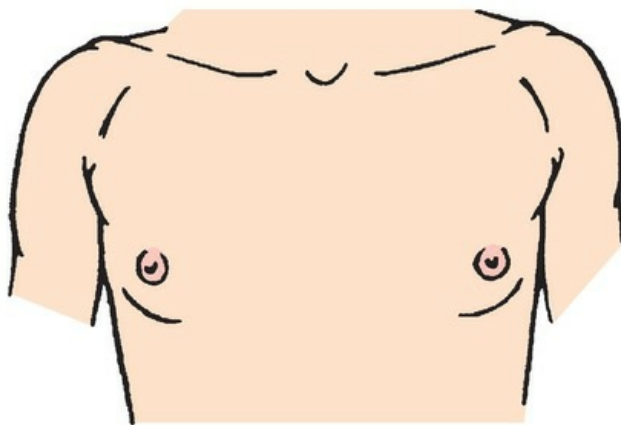

47. A nurse compares a child's height and weight with standard growth charts and finds the child to be in the 50th percentile for height and in the 25th percentile for weight. The nurse interprets these findings as indicating that the child is:

- ☐ 1. typical height and weight.
- ☐ 2. overweight for height.
- ☐ 3. underweight for height.
- ☐ 4. abnormal in height.

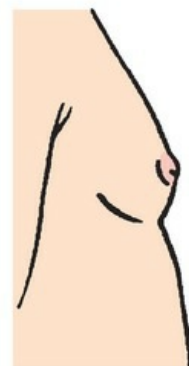

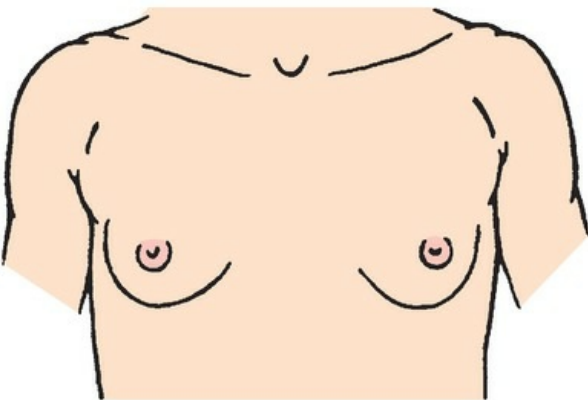

Health Promotion of the Adolescent and Family

48. The nurse is assessing an 11-year-old female, using the Tanner staging of puberty. Which finding indicates preadolescent development of the breasts?

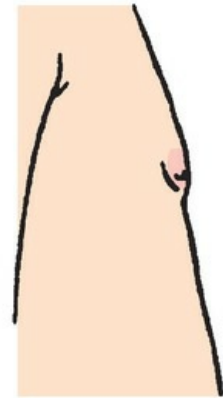

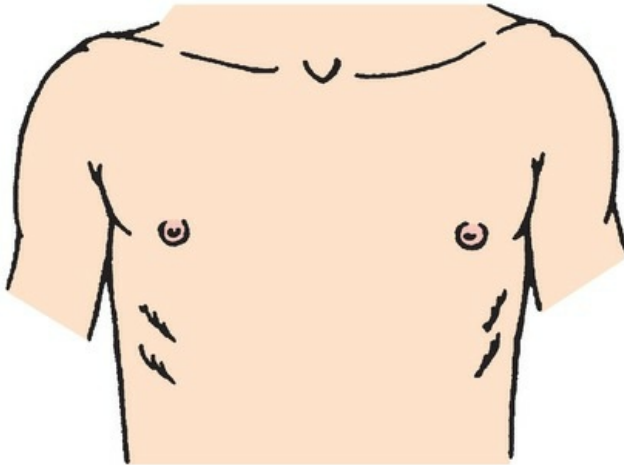

- ☐ 1.

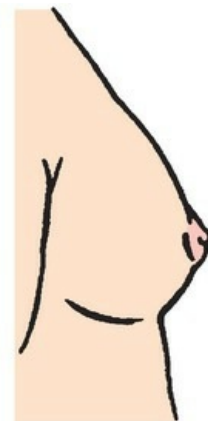

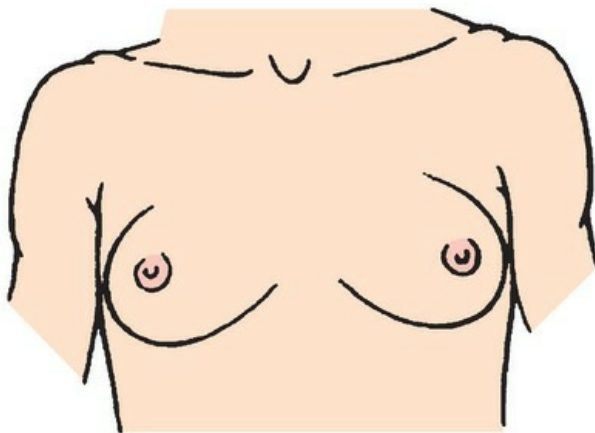

- ☐ 2.

- ☐ 3.

☐ 4.

49. The parents of a 12-year-old girl ask why their daughter, who is not sexually active, should receive the human papillomavirus (HPV) vaccine. The nurse should tell the parents:

- ☐ 1. "The vaccine is most effective against cervical cancer if given before becoming sexually active."
- ☐ 2. "Parents are never sure when their child might become sexually active."
- ☐ 3. "HPV is most common in teens and women in their late 20s."
- ☐ 4. "If your daughter is sexually assaulted, she may be exposed to HPV."

50. The nurse is teaching an adolescent with asthma how to use an inhaler. In which order should the nurse instruct the client to follow the steps from first to last? All options must be used.

1. Put the inhaler in your mouth.

2. Breathe out.

3. Depress the top of the inhaler.

4. Begin to slowly breath in.

5. Hold the breath 5 to 10 seconds.

6. Shake the inhaler.

51. A 16-year-old client and who has been confined to a wheelchair since early childhood has lately been acting rebellious and rude. Her parents ask the nurse, “Are all adolescents like this?” The nurse should respond with which statement?

- ☐ 1. “Yes, although your daughter’s behaviors are more like those of an adolescent boy.”
- ☐ 2. “No. Your daughter must need some help in dealing with her feelings.”
- ☐ 3. “Your daughter’s behavior seems to be typical adolescent behavior. Let

us talk more about it.”

☐ 4. “Your daughter’s behavior results from feelings about her disability: ignore them.”

52. The parents of an adolescent boy are concerned their son seems to need 9 hours of sleep a night. The nurse should advise the parents:

☐ 1. “As long as he seems otherwise well, this sounds like a typical teenager.”

☐ 2. “Adolescents need only 8 hours of sleep a night; anything over this is excessive.”

☐ 3. “Your son is probably engaged in too many activities and is wearing himself out.”

☐ 4. “The side effect of many drugs is sleepiness.”

53. An adolescent tells the nurse that she would like to use tampons during her period. The nurse should **first**:

☐ 1. assess her usual menstrual flow pattern.

☐ 2. determine whether she is sexually active.

☐ 3. provide information about preventing toxic shock syndrome.

☐ 4. refer her to a specialist in adolescent gynecology.

54. Several high-school seniors are referred to the nurse because of suspected alcohol misuse. When the nurse assesses the situation, what would be **most** important to determine?

☐ 1. what they know about the legal implications of drinking

☐ 2. the type of alcohol they usually drink

☐ 3. the reasons they choose to use alcohol

☐ 4. when and with whom they use alcohol

Common Childhood and Adolescent Health Problems

55. Which action initiated by the parents of an 8-month-old indicates they need further teaching about preventing childhood accidents?

☐ 1. placing a fire screen in front of the fireplace

☐ 2. placing a car seat in a front-seat, front-facing position

☐ 3. inspecting toys for loose parts

- ☐ 4. placing toxic substances out of reach or in a locked cabinet

56. A nurse is assessing the growth and development of a 14-year-old boy. He reports that his 13-year-old sister is 2 inches (5 cm) taller than he is. The nurse should advise the boy that the growth spurt in adolescent boys, compared with the growth spurt of adolescent girls:

- ☐ 1. occurs about at the same time.
- ☐ 2. occurs about 2 years earlier.
- ☐ 3. occurs about 2 years later.
- ☐ 4. occurs about 1 year earlier.

57. Parents of a 15-year-old state that their child is moody and rude. The nurse should advise the parents to:

- ☐ 1. restrict their child's activities.
- ☐ 2. discuss their feelings with their child.
- ☐ 3. obtain family counseling.
- ☐ 4. talk to other parents of adolescents.

58. Which statement by a parent whose child was just diagnosed with pediculosis capitis (head lice) demonstrates an understanding of the safety and efficacy of the common medications used to treat the infection?

- ☐ 1. "I am going to request a prescription for lindane since it works the best."
- ☐ 2. "After I shampoo, I will use the special comb to get the nits out."
- ☐ 3. "Most OTC lice treatments are 100% effective at killing all the eggs."
- ☐ 4. "I like the OTC lice treatments because you can give a second treatment the next day if any lice remain."

59. A parent asks, "Can I get head lice too?" The nurse indicates that adults can also be infested with head lice but that pediculosis is more common among school-age children, primarily for what reason?

- ☐ 1. An immunity to pediculosis usually is established by adulthood.
- ☐ 2. School-age children tend to be more neglectful of frequent handwashing.
- ☐ 3. Pediculosis usually is spread by close contact with infested children.
- ☐ 4. The skin of adults is more capable of resisting the invasion of lice.

60. After teaching the parents about the cause of ringworm of the scalp (tinea capitis), which statement by the parent indicates successful teaching?

- ☐ 1. "It results from overexposure to the sun."
- ☐ 2. "It is caused by infestation with a mite."
- ☐ 3. "It is a fungal infection of the scalp."
- ☐ 4. "It is an allergic reaction."

61. Griseofulvin was prescribed to treat a child's ringworm of the scalp. The nurse instructs the parents to use the medication for several weeks for which reason?

- ☐ 1. A sensitivity to the drug is less likely if it is used over a period of time.
- ☐ 2. Fewer side effects occur as the body slowly adjusts to a new substance over time.
- ☐ 3. Fewer allergic reactions occur if the drug is maintained at the same level long-term.
- ☐ 4. The growth of the causative organism into new cells is prevented with long-term use.

62. A parent asks the nurse, "How did my children get pinworms?" The nurse explains that pinworms are **most** commonly spread by which route?

- ☐ 1. food
- ☐ 2. hands
- ☐ 3. animals
- ☐ 4. toilet seats

63. A parent asks the nurse how to care for a child with chickenpox. What should the nurse include in the plan of care? Select all that apply.

- ☐ 1. Use OTC aspirin for fever.
- ☐ 2. Encourage oatmeal baths.
- ☐ 3. Keep fingernails short.
- ☐ 4. Avoid overheating.
- ☐ 5. Do not return to school until all lesions have crusted over.

64. A mother states that a healthcare provider (HCP) described her daughter as having 20/60 vision, and she asks the nurse what this means. The

nurse responds based on the interpretation that the child is experiencing which condition?

- ☐ 1. a loss of approximately one-third of her visual acuity
- ☐ 2. ability to see at 60 feet what she should see at 20 feet
- ☐ 3. ability to see at 20 feet what she should see at 60 feet
- ☐ 4. visual acuity three times better than average

65. The nurse discusses the eating habits of school-age children with their parents, explaining that these habits are **most** influenced by:

- ☐ 1. food preferences of their peers.
- ☐ 2. smell and appearance of foods offered.
- ☐ 3. examples provided by parents at mealtimes.
- ☐ 4. parental encouragement to eat nutritious foods.

66. When discussing the onset of adolescence with parents, the nurse explains that it occurs at what time?

- ☐ 1. same age for both boys and girls
- ☐ 2. 1 to 2 years earlier in boys than in girls
- ☐ 3. 1 to 2 years earlier in girls than in boys
- ☐ 4. 3 to 4 years later in boys than in girls

67. A mother has heard that several children have been diagnosed with mononucleosis. She asks the nurse what precautions should be taken to prevent this from occurring in her child. The nurse should instruct the mother to:

- ☐ 1. take no particular precautionary measures.
- ☐ 2. sterilize the child's eating utensils before they are reused.
- ☐ 3. wash the child's linens separately in hot, soapy water.
- ☐ 4. have the child vaccinated.

68. A father asks the nurse how he would know if his child had developed mononucleosis. The nurse explains that in addition to fatigue, which symptom would be **most** common?

- ☐ 1. liver tenderness
- ☐ 2. enlarged lymph glands

- ☐ 3. persistent nonproductive cough
- ☐ 4. a blush-like generalized skin rash

Managing Care, Quality, and Safety of Children

69. A 17-year-old high school senior calls the clinic because she thinks she might have gonorrhea. She wants to be seen but wants assurances that no one will know. Which is the **most** appropriate response by the nurse?

- ☐ 1. “Because you are underage, we will need your parent’s consent to treat you.”
- ☐ 2. “We can treat you without your parents’ consent, but they have the right to review your medical record.”
- ☐ 3. “We can see you without your parents’ consent but have to report any positive results to the public health department.”
- ☐ 4. “We can see you and will not share your results with anyone.”

70. A parent brings a 5-year-old child to a weekend vaccination clinic to prepare for school entry. The nurse notes that the child has not had any vaccinations since 4 months of age. What is the **best** way for the nurse to determine how to catch up the child’s vaccinations?

- ☐ 1. Ask the child’s healthcare provider (HCP).
- ☐ 2. Check nationally published immunization guidelines.
- ☐ 3. Read each vaccine’s manufacturer’s insert.
- ☐ 4. Contact the pharmacist.

71. A 13-month-old has a febrile seizure 3 weeks after the administration of the chickenpox vaccine. The nurse should:

- ☐ 1. recognize that the events are unrelated.
- ☐ 2. report the event through an immunization surveillance system.
- ☐ 3. explain to the parents that this is a rare but acceptable risk.
- ☐ 4. refer the child to a neurologist.

72. The nurse is invited to attend a meeting with several parents who express frustration with the amount of time their adolescents spend in front of the mirror and the length of time it takes them to get dressed. The nurse explains that this behavior indicates:

- ☐ 1. an abnormal narcissism.
- ☐ 2. a method of procrastination.
- ☐ 3. a way of testing the parents' limit-setting.
- ☐ 4. a result of developing self-concept.

73. A child who is 18 months of age is brought to the emergency department by her babysitter. The babysitter states, "She fell from the sofa an hour ago and has not been herself since." On questioning, the babysitter appears to be unsure of time and other facts about the incident. Which question below would be **most** effective in obtaining more information about the child's injuries?

- ☐ 1. "Why did you leave the child alone on the couch?"
- ☐ 2. "Have you taken a course in safe babysitting?"
- ☐ 3. "Tell me what was happening before she fell."
- ☐ 4. "Where are her parents? Do they know this happened?"

Answers, Rationales, and Test-Taking Strategies

*The answers and rationales for each question follow below, along with keys () to the client need (CN) and cognitive level (CL) for each question. In addition, you will also see a glossary icon () highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 12–23 and pages 35–36 in Part 1 of this book.*

Health Promotion of the Infant and Family

1. 2. By trying to determine the source of parents' concerns, the nurse is able to acknowledge their feelings and provide the most appropriate information. This approach increases the likelihood parents will listen to the **healthcare provider's (HCP's)** views. Exemptions for vaccines vary by state, province, or territory, and many parents feel legal requirements for

vaccinations take away parental rights. The number of vaccinations given at one time may not be the issue. Waivers are used only if clients refuse vaccination after a discussion of risks and benefits.

CN: Health promotion and maintenance; CL: Synthesize

2. 3. It is important for the nurse to assist parents in assessing speech development in their child so that developmental delays can be identified early. According to the Denver Developmental Screening Examination, at 8 months of age, the child should say “mama” and “dada” nonspecifically and imitate speech sounds. Children cannot say “dada” or “mama” specifically or use more than three words until they are about 12 months of age. A child cannot respond to specific commands or point to objects when requested until about 17 months of age.

CN: Health promotion and maintenance; CL: Apply

3. 4. According to the Denver Developmental Screening Examination, a child of 8 months should sit without support for long periods of time. An 8-month-old child does not have the ability to stand without hanging onto a stationary object for support. His or her muscles are not developed enough to support all his weight without assistance. His or her balance has not developed to the point that he or she can stand and stoop over to reach an object.

CN: Health promotion and maintenance; CL: Synthesize

4. 4. Infants should be kept on formula or breast milk until 1 year of age. The protein in cow’s milk is harder to digest than is that found in formula. It does not matter in what order fruits and vegetables are introduced as long as the foods are introduced slowly. Solids are introduced into the infant’s diet around 4 to 6 months, after the extrusion reflex has diminished and when the child will accept new textures. Iron deficiency develops in term infants between 4 to 6 months when the prenatal iron stores are depleted. Fortified cereals can be added to the infant’s diet at 4 to 6 months to prevent iron deficiency anemia.

CN: Health promotion and maintenance; CL: Create

5. 3. Understanding object permanence means that the child is aware of the

existence of objects that are covered or displaced. Neuromuscular development, curiosity, and the ability to transfer objects are not associated with the principle of object permanence. Although, at 10 months, neuromuscular development is sufficient to grasp objects and a child's curiosity has increased, neither are related to the thought process involved in object permanence.

CN: Health promotion and maintenance; CL: Apply

6. 3. The posterior fontanelle should be closed by age 2 months. The anterior fontanelle and sagittal and frontal sutures should be closed by age 18 months.

CN Health promotion and maintenance; CL: Apply

7. 1. New guidelines recommend that parents keep their toddlers in a rear-facing car seat until 2 years of age or they reach maximum height and weight for the seat. Car seats are marked with an expiration date because the integrity of the plastic may deteriorate with age. Booster seats are recommended for older children until they are 4 feet 9 inches (144.8 cm). This typically occurs between the ages 8 and 12 years. Children should ride in the back seat until they are 13 years of age to minimize injury should airbags be deployed.

CN: Health promotion and maintenance; CL: Evaluate

8. 3. During the first few months of life, an infant's eyes may wander and appear to be crossing. As the eye muscles mature, between 2 and 3 months of age, both eyes will focus on the same thing. No intervention is necessary, as crossing of the eyes is normal in the first few months of life.

CN: Health promotion and maintenance; CL: Apply

9. 3. By the end of 3 months, infants should babble. Lack of babbling suggests a language delay and warrants further investigation. Infants typically would begin playing peekaboo around 7 months. The ability to roll front to back typically occurs at 5 months. Sitting unsupported is expected at 6 months.

CN: Health promotion and maintenance; CL: Analyze

10. 3. Vaccination in the presence of a moderate-to-severe infection, with or without fever, increases the risk of injury and decreases the chance of mounting good immunity. There is currently no evidence to suggest vaccines raise the risk of SIDS. A mild temperature may be expected with the DTaP. A fever of $>40.5^{\circ}\text{C}$ (105°F) within 48 hours of vaccination would warrant caution. The DTaP is not a live vaccine. No special precautions are needed regarding immunosuppressed family members.

CN: Reduction of risk potential; CL: Synthesize

11. 3. The MMR is a live vaccine. Neither the American Academy of Pediatrics nor the Public Health Agency of Canada recommends routine vaccination with the MMR (either alone or combined with the varicella vaccine) to children younger than 12 months. The DTaP, Hib, and influenza are all indicated.

CN: Health promotion and maintenance; CL: Synthesize

12. 4. A 1-month-old infant is usually able to lift the head from a prone position. The full-term infant with no complications has probably been able to do this since birth. Smiling and laughing is expected behavior at 2 to 3 months. Rolling from back to side and holding a rattle are characteristics of a 4-month-old.

CN: Health promotion and maintenance; CL: Analyze

13. 3. The American Academy of Pediatrics and Canadian Pediatric Society recommend that infants remain on iron-fortified formula or breast milk until 1 year of age. The nurse needs to first assess if the parent switched the baby prematurely due to lack of information or lack of resources. Then appropriate teaching or referrals may be determined. At 1 year of age, the infant may be switched to whole milk, which has a higher fat content than 2%. The higher fat content is needed for brain growth. Demanding clients change behaviors without addressing the cause is unlikely to produce desired results.

CN: Health promotion and maintenance; CL: Analyze

14. 2. Holding the head erect when sitting, staring at an object placed in the hand, taking the object to the mouth, cooing and gurgling, and sustaining

part of his body weight when in a standing position are behaviors characteristic of a 4-month-old infant. A 2-month-old typically vocalizes, follows objects to the midline, and smiles. A 7-month-old typically is able to sit without support, turns toward the voice, and transfers objects from hand to hand. Usually, a 9-month-old can crawl, stand while holding on, and initiate speech sounds.

CN: Health promotion and maintenance; CL: Analyze

15. 3,6. Typical abilities demonstrated by 8-month-old infants include playing peekaboo and transferring objects from one hand to another. The ability to say “dada” and “mama” is more typical of 10-month-old infants. Infants usually are at least 12 months old when they achieve the ability to walk independently. Infants who are 15 months old commonly can feed themselves with a spoon and stack two blocks.

CN: Health promotion and maintenance; CL: Analyze

16. 4. The anterior fontanelle, commonly known as the soft spot, closes between 12 to 18 months in most infants. The nurse normally measures an infant’s occipital frontal circumference at each well-child visit. This action alone does not relieve the parent’s concerns. Referrals would be indicated for premature or delayed closures of the fontanelle especially if there were other abnormal findings. Closure of the anterior fontanelle by 12 months can only be expected to occur in approximately a third of all infants.

CN: Health promotion and maintenance; CL: Synthesize

17. 1. Typically, a 9-month-old infant should have been voicing single syllables since 6 months of age. Absence of this finding would be a cause for concern. An infant usually is able to stand alone at about 10 months of age. An infant usually is able to build a tower of two cubes at about 15 months of age. An infant usually is able to drink from a cup with little spilling at about 15 months of age.

CN: Health promotion and maintenance; CL: Analyze

18. 4. More than 90% of 9-month-olds are able to stand holding onto objects. Rolling over is expected at 4 to 6 months, and sitting without support is expected at 6 months. Crawling is expected at 9 months.

 CN: Health promotion and maintenance; CL: Analyze

19. 2. Simultaneous injection reduces the anxiety from anticipation of the next injection. Needle length must be long enough to deposit the vaccine into the muscle. A 5/8-inch (1.6-cm) needle is appropriate for newborns but is not long enough for infants older than 1 month or other children. Aspirating for blood return does not confirm needle placement. Breast-feeding during vaccinations, not before, has been found to reduce pain.

 CN: Basic care and comfort; CL: Apply

Health Promotion of the Toddler and Family

20. 3. A push-pull toy will aid in development of gross motor skills and muscle development. A stuffed animal is age appropriate for a toddler but is not the toy to promote development. A music box and nursery mobile are most appropriate to stimulate development for an infant.

 CN: Health promotion and maintenance; CL: Apply

21. 3. Behavior problems related to sleep and rest are common in young children. Consistent rituals around bedtime help to create an easier transition from waking to sleep. Allowing a child to sleep with his parents commonly creates more problems for the family and child and does not alleviate the problem or foster autonomy. Increasing activity before bedtime does not alleviate the separation anxiety in the toddler and causes further anxiety. Allowing him to stay up later than his normal time for bed will increase his anxiety, make it more difficult for him to fall asleep, and do nothing to lessen his fear.

 CN: Psychosocial integrity; CL: Synthesize

22. 4. Toddlers establish ritualistic patterns to feel secure, despite inconsistencies in their environment. Establishing a sense of identity is the developmental task of the adolescent. The toddler's developmental task is to use rituals and routines to help in making autonomy easier to accomplish. Ritualistic patterns do involve patterns of behavior, but they are not utilized to develop learning behaviors.

 CN: Psychosocial integrity; CL: Apply

23. 1,3,4. Readiness for toilet training is based on neurological, psychological, and physical developmental readiness. The nurse can introduce concepts of readiness for toilet training and encourage parents to look for adaptive and psychomotor signs such as the ability to walk well, balance, climb, sit in a chair, dress oneself, please the parent, and communicate awareness of the need to urinate or defecate. Chronological age is not an indicator for toilet training. Two-year-olds engage in parallel play, which is not an indicator of readiness for toilet training.

CN: Health promotion and maintenance; CL: Apply

24. 3. A child will regress to a behavior used in an earlier stage of development in order to cope with a perceived threatening situation. Readiness for toilet training should be based on neurological, physical, and psychological development, not the age of the child. Children are afraid of hospitalization, but the bed-wetting is a compensatory mechanism done to regress to a previous stage of development that is more comfortable and secure for the child. Telling the mother that bed-wetting is related to fluid intake does not provide an adequate explanation for the underlying regression to an earlier stage of development.

CN: Psychosocial integrity; CL: Synthesize

25. 3,2,1,4. When obtaining a urine specimen from an infant, the nurse assists the client to drink fluids 30 to 60 minutes prior to specimen collection so the client voids as soon as possible after the collection bag is applied. Next, the nurse applies gloves and then cleanses the genital area with sterile water to prevent contamination of the urine. Finally, the nurse applies the collection bag and then removes the bag when the specimen is obtained.

CN: Safety and infection control; CL: apply

26. 3. A craving to eat nonfood substances is known as pica. Toddlers use oral gratification as a means to cope with anxiety. Therefore, the nurse should first assess whether the child is experiencing any change in the home environment that could cause anxiety. Teething or the eruption of large teeth and the amount of attention from the mother are unlikely causes of pica. Nutritional deficiencies, especially iron deficiency, were once thought to cause pica, but research has not substantiated this theory. A soft, low-

roughage diet is an unlikely cause.

CN: Physiological adaptation; CL: Analyze

27. 3. A 2-year-old child usually can kick a ball forward. Riding a tricycle is characteristic of a 3-year-old child. Tying shoelaces is a behavior to be expected of a 5-year-old child. Using blunt scissors is characteristic of a 3-year-old child.

CN: Health promotion and maintenance; CL: Analyze

28. 2. Parents can be asked to assist when their child becomes uncooperative during a procedure. Most commonly, the child's difficulty in cooperating is caused by fear. In most situations, the child will feel more secure with a parent present. Other methods, such as asking another nurse to assist or waiting until the child calms down, may be necessary, but obtaining a parent's assistance is the recommended first action. Restraints should be used only as a last resort, after all other attempts have been made to encourage cooperation.

CN: Health promotion and maintenance; CL: Synthesize

29. 4. In a child younger than 3 years of age, the pinna is pulled back and down because the auditory canals are almost straight in children. In children over 3 through adulthood, the pinna is pulled up and backward because the auditory canals are directed inward, forward, and down.

CN: Pharmacological and parenteral therapies; CL: Evaluate

30. 4. Time-out is the most appropriate discipline for toddlers. It helps to remove them from the situation and allows them to regain control. Structuring interactions with 3-year-olds helps minimize unacceptable behavior. This approach involves setting clear and reasonable rules and calling attention to unacceptable behavior as soon as it occurs. Reprimanding a young child can reinforce undesirable behavior over time because it provides attention. Physical punishment, such as spanking, has limited effectiveness and serious negative effects. Reasoning is more appropriate for older children, such as preschoolers and those older, especially when moral issues are involved. Unfortunately, reasoning combined with scolding often takes the form of shame or criticism, and children take such remarks

seriously, believing that they are “bad.”

CN: Health promotion and maintenance; CL: Synthesize

31. 2. Toddlers usually express pain through such behaviors as restlessness, facial grimaces, irritability, and crying. It is not particularly helpful to ask toddlers about pain. In most instances, they would be unable to understand or describe the nature and location of their pain because of their lack of verbal and cognitive skills. However, preschool and older children have the verbal and cognitive skills to be able to respond appropriately. While the FACES pain scale can be used in young children, numeric rating pain scales are more appropriate for children who are of school age or older. Changes in vital signs do occur as a result of pain, but behavioral changes usually are noticed first.

CN: Physiological adaptation; CL: Analyze

32. 2. Toddlers around the age of 15 months need 2 to 3 cups (500 to 750 mL) of milk per day to supply necessary nutrients such as calcium. A daily intake of more than 3 cups (750 mL) of milk may interfere with the ingestion of other necessary nutrients.

CN: Health promotion and maintenance; CL: Apply

Health Promotion of the Preschooler and Family

33. 4. Dark urine is not a potential side effect of taking an iron supplement. Families need education about the possible side effects, including placing liquid iron behind the teeth to avoid teeth staining. Stools may become dark in color, even turn black, and some clients may experience anorexia.

CN: Pharmacological and parenteral therapies; CL: Evaluate

34. 2. Preschool-age children have been described as powerhouses of gross motor activity who seem to have endless energy. A limitation of their motor ability is that in moving as quickly as they do, they are not always able to judge distances, nor are they able to estimate the amount of strength and balance needed for activities. As a result, they have frequent mishaps. This level of activity typically is not associated with changes at home. However, if

the behavior intensifies, a referral to a pediatric neurologist would be appropriate. Children who have been abused usually demonstrate withdrawn behaviors, not endless energy.

CN: Health promotion and maintenance; CL: Synthesize

35. 2. Bedtime is often a problem with preschoolers. Recommendations for reducing conflicts at bedtime include establishing a set bedtime, having a dependable routine, such as story reading, and conveying the expectation that the child will comply. Allowing the child to stay up late one or two nights interferes with establishing the needed bedtime rituals. Excitement, such as active play, just before bedtime should be avoided because it stimulates the child, making it difficult for the child to calm down and prepare for sleep. Using food such as a cookie as a reward if bedtime is pleasant should be avoided because it places too much importance on food. Other rewards, such as stickers, could be used as an alternative.

CN: Health promotion and maintenance; CL: Synthesize

36. 1,2. Some parents find that putting the child in time-out until control is regained is very effective. Others find that ignoring the behaviors works just as well with their child. Both suggestions are appropriate to include in the teaching plan. Spanking the child is never an option. Attempting to reason with a child having a temper tantrum does not work because the child is out of control. A more appropriate time to discuss it with the child is when the child regains control.

CN: Health promotion and maintenance; CL: Create

37. 3. Children younger than 7 years of age do not have the manual dexterity needed for tooth brushing. Therefore, parents need to help with this task until that time.

CN: Health promotion and maintenance; CL: Evaluate

38. 2. The preschool-age child does not have an accurate concept of skin integrity and can view medical and surgical treatments as hostile invasions that can destroy or damage the body. The child does not understand that exsanguinations will not occur from the injection site. Here, the child is verbalizing a fear consistent with the developmental age. The child would

most likely verbalize concerns of not wanting another procedure or exhibit other symptoms associated with pain if those were the underlying issues. If control was the main issue, the child would try to control more than just the bandage removal.

CN: Psychosocial integrity; CL: Analyze

39. 3. Family changes and stresses (e.g., moving, having company, taking a vacation, adding a new member) can distract parents and contribute to accidents. Only children typically receive more attention than those with siblings. Thus, the risk would be less. Families who live in the suburbs frequently are more affluent and, therefore, better able to maintain a home less conducive to accidents. A parent's formal education is unrelated to accidents.

CN: Health promotion and maintenance; CL: Synthesize

40. 3. Preschool-age children may view illness as punishment for their fantasies. At this age, children do not have the cognitive ability to separate fantasies from reality and may expect to be punished for their "evil thoughts." Viewing illness as a necessary part of life requires a higher level of cognition than preschoolers possess. This view is seen in children of middle school age and older. Perceiving illness as a test of self-worth or as the will of God is more characteristic of adults.

CN: Health promotion and maintenance; CL: Apply

Health Promotion of the School-Age Child and Family

41. 1,3,4. Blood pressures percentiles for children are referenced by the age, sex, and height. Measurements at or above the 95th percentile are considered indicative of hypertension. Weight and elevated BMI contribute to hypertension but are not used to define it. The OFC is not routinely measured in children over 2 years of age and is not used to reference blood pressure readings.

CN: Health promotion and maintenance; CL: Analyze

42. 4. School-age children are concerned about justice and fair play. They become upset when they think someone is not playing fair. Physical affection

makes them embarrassed and uncomfortable. They are concerned about others and are cooperative in play and school.

CN: Health promotion and maintenance; CL: Analyze

43. 3. During the school-age years, children learn to socialize with children of the same age. The “best friend” stage, which occurs around 9 or 10 years of age, is important in providing a foundation for self-esteem and later relationships. Thinking independently, organizing, and planning are cognitive skills. Active play relates to motor skills.

CN: Health promotion and maintenance; CL: Analyze

44. 2. Children are capable of mastering the skills required for flossing when they reach 9 years of age. At this age, many children are able to assume responsibility for personal hygiene. She is not too young to assume this responsibility, and she should not have been expected to assume this responsibility much earlier. It is not likely that she is exaggerating; this is an expected behavior at this age.

CN: Health promotion and maintenance; CL: Analyze

45. 2. School-age children delight in riddles and jokes. Mastery of the ambiguities of language and of sentence structure allows the school-age child to manipulate words, and telling riddles and jokes is a way of practicing this skill. Children who suffer from inadequate attention from parents tend to demonstrate abnormal behavior. Peer influence is less important to school-age children, and while the child may learn the joke from a friend, he or she is telling the joke to master language. Watching television does not influence the extent of joke telling.

CN: Health promotion and maintenance; CL: Analyze

46. 3. Snacks are necessary for school-age children because of their high energy level. School-age children are in a stage of cognitive development in which they can learn to categorize or classify and can also learn cause and effect. By preparing their own snacks, children can learn the basics of nutrition (such as what carbohydrates are and what happens when they are eaten). The mother and child should make the decision about appropriate foods together. School-age children learn to make decisions based on

information, not instinct. Some knowledge of nutrition is needed to make appropriate choices.

CN: Health promotion and maintenance; CL: Synthesize

47. 1. The values of height and weight percentiles are usually similar for an individual child. Measurements between the 5th and 95th percentiles are considered normal. Marked discrepancies identify overweight or underweight children.

CN: Health promotion and maintenance; CL: Analyze

Health Promotion of the Adolescent and Family

48. 3. This figure indicates elevation of the papilla, without breast buds, considered stage 1 and typical of a preadolescent. Figure 1 shows stage 2, breast bud enlargement; there is elevation of the breast and the diameter of the areola has increased. Figure 2 shows stage 3, enlargement of the breast and areola. Figure 4 shows stage 4, in which there is projection of areola and papilla to form a secondary mound above the level of the breast.

CN: Physiological adaptation; CL: Analyze

49. 1. Vaccines are preventative in nature and ideally given before exposure. Focusing on the benefits of cancer prevention is most appropriate, as opposed to discussing with parents the potential that their child may become sexually active without their knowledge. It is true HPV is most common in adolescents and women in their late twenties, but parents still may not perceive that their child is at risk. Discussing the possibility of exposure through assault raises fears and does not focus on prevention.

CN: Health promotion and maintenance; CL: Apply

50. 6,2,1,4,3,5. When dispensing medication from an inhaler, the client should first shake the inhaler and then breathe out through the mouth before putting the inhaler in the mouth. Next, the client inhales slowly and then presses the canister to dispense the medication while continuing to inhale. The client should hold the breath for 5 to 10 seconds before exhaling.

CN: Pharmacological and parenteral therapies; CL: Apply

51. 3. It is normal behavior for adolescents to assert independence and begin to separate from their parents; the behavior is not changed by their daughter's disability, nor is it unique to a girl. The nurse offers reassurance to the parents and then opens the conversation for additional discussion.

 CN: Health promotion; CL: Analyze

52. 1. Many teenagers feel fatigued from a combination of fast-food diets, many activities, and a rapid growth spurt; this is normal behavior, and the nurse should explain possible reasons for the sleep pattern. Adolescents typically need 8.5 to 9.5 hours of sleep. There are no data to suggest that activities are tiring this teenager. It is not appropriate to suggest the child is taking drugs based on the question the parents are asking the nurse.

 CN: Health Promotion; CL: Analyze

53. 3. The nurse should provide the adolescent with information about toxic shock syndrome because of the identified relationship between tampon use and the syndrome's development. Additionally, about 95% of cases of toxic shock syndrome occur during menses. Most adolescent females can use tampons safely if they change them frequently. Using tampons is not related to menstrual flow or sexual activity. There is no need to refer the girl to a gynecologist; a nurse can provide health teaching about tampon use.

 CN: Reduction of risk potential; CL: Synthesize

54. 3. Information about why adolescents choose to use alcohol or other drugs can be used to determine whether they are becoming responsible users or problem users. The senior students likely know the legal implications of drinking, and the nurse will establish a more effective relationship with the students by understanding motivations for use. The type of alcohol and when and with whom they are using it are not the first data to obtain when assessing the situation.

 CN: Health promotion and maintenance; CL: Analyze

Common Childhood and Adolescent Health Problems

55. 2. It is recommended that children up to 2 years of age ride in a rear-facing car seat. The middle of the back seat is considered the safest area of

the car. Burns are a major cause of childhood accidents, and using fire screens in front of fireplaces can help prevent children from getting too close to a fire in a fireplace. Toys that contain loose parts or plastic eyes that can be swallowed or aspirated by small children should be avoided. Parents should inspect all toys for these parts before giving one to a child. Poisonings are most commonly caused by improper storage of a toxic substance. Keeping toxic substances in a childproof container in a locked cabinet and continually observing the child's activities can prevent most poisonings.

CN: Safety and infection control; CL: Evaluate

56. 3. Adolescent boys lag about 2 years behind adolescent girls in growth. Most girls are 1 to 2 inches (3 to 5 cm) taller than boys at the beginning of adolescence but tend to stop growing approximately 2 to 3 years after menarche with the closure of the epiphyseal lines of the long bones.

CN: Health promotion and maintenance; CL: Apply

57. 2. Parents need to discuss with their adolescent how they perceive his or her behavior and how they feel about it. Moodiness is characteristic of adolescents. The adolescent may have a reason for or not be aware of his behavior. Restricting the adolescent's activities will not change his or her mood or the way he or she responds to others. It may increase his or her unacceptable responses. Counseling may not be needed at this time if the parents are open to communicating and listening to the adolescent. Talking to other parents may be of some help, but what is helpful to others may not be helpful to their child.

CN: Health promotion and maintenance; CL: Synthesize

58. 2. The makers of many of the pediculicides recommend manual removal of the nits following treatment with an extra-fine-tooth comb. None of the pediculicides are 100% effective in killing all the eggs. The FDA has issued a warning regarding the use of lindane because of the potential for neurotoxicity. Clients are treated with lindane only when the benefits outweigh the risks. Lice treatments may be repeated in 7 to 10 days; the next day is too soon.

CN: Health promotion; CL: synthesize

59. 3. Lice are spread by close personal contact and by contact with infested clothing, bed and bathroom linens, and combs and brushes. Lice are more common in school-age children than in adults because of the close contact in school or at sleepovers and the common practice of sharing possessions. Lice are not commonly spread by hand contact. There is no immunity conferred by having head lice. Adults can have head lice, particularly if they come in close contact with their children's infested clothing or linens.

CN: Physiological adaptation; CL: Apply

60. 3. Ringworm of the scalp is caused by a fungus of the dermatophyte group of the species. Overexposure to the sun would result in sunburn. Mites, such as chiggers or ticks, produce bites on the skin, resulting in inflammation. An allergic reaction commonly is manifested by hives, rash, or anaphylaxis.

CN: Physiological adaptation; CL: Evaluate

61. 4. Griseofulvin is an antifungal agent that acts by binding to the keratin that is deposited in the skin, hair, and nails as they grow. This keratin is then resistant to the fungus. But as the keratin is normally shed, the fungus enters new, uninfected cells unless drug therapy continues. Long-term administration of griseofulvin does not prevent sensitivity or allergic reactions. As the body adjusts to a new substance over time, side effects are variable and do not necessarily decrease.

CN: Pharmacological and parenteral therapies; CL: Apply

62. 2. The adult pinworm emerges from the rectum and colon at night onto the perianal area to lay its eggs. Itching and scratching introduces the eggs to the hands, from where they can easily reinfect the child or infect others. Nightclothes and bed linens can be sources of infection. The eggs can also be transmitted by dust in the home. Although transmission through contaminated food and water supplies is possible, it is rare. Contaminated animals can spread histoplasmosis and salmonella. The spread of infections by toilet seats has not been supported by research.

CN: Physiological adaptation; CL: Apply

63. 2,3,4,5. The care of a child with chickenpox focuses keeping the child

comfortable and preventing infection in the lesions. Oatmeal baths may ease severe itching. Keeping fingernails short reduces trauma from scratching and helps prevent skin infections. Overheating can make itching worse. Children may return to school once all lesions have crusted over. The use of aspirin in children with chickenpox is contraindicated because it has been linked to Reye syndrome.

CN: Basic care and comfort; CL: Synthesize

64. 3. A child with 20/60 vision sees at 20 feet what those with 20/20 vision see at 60 feet. A visual acuity of 20/200 is considered to be the boundary of legal blindness.

CN: Physiological adaptation; CL: Analyze

65. 3. Although children may be influenced by their peers and smell and appearance of foods may be important, children are most likely to be influenced by the example and atmosphere provided by their parents. Coaxing and badgering a child to eat most likely will aggravate poor eating habits.

CN: Health promotion and maintenance; CL: Apply

66. 3. Girls experience the onset of adolescence about 1 to 2 years earlier than do boys. The reason for this is not understood.

CN: Health promotion and maintenance; CL: Apply

67. 1. The cause of infectious mononucleosis is thought to be the Epstein-Barr virus. The virus is believed to be spread only by direct intimate contact. No precautionary measures for the general public are recommended to prevent mononucleosis. However, it is recommended that sharing food items and kissing be avoided with persons known to have mononucleosis. There currently is no vaccine for the disease.

CN: Physiological adaptation; CL: Synthesize

68. 2. Mononucleosis usually has an insidious onset, with fatigue and the inability to maintain usual activity levels as the most common symptoms. The lymph nodes are typically enlarged, and the spleen also may be enlarged. Fever and a sore throat often accompany mononucleosis. A persistent

nonproductive cough can follow an upper respiratory tract infection. A blush-like generalized skin rash is more characteristic of rubella.

CN: Physiological adaptation; CL: Analyze

Managing Care, Quality, and Safety of Children

69. 3. While some areas may specify a minimum age for treatment (usually 12 to 14 years), generally adolescents have the right to seek treatment for sexually transmitted infections without their parents' permission. These **medical records**  are not shared with parents without the client's permission. However, adolescents must be made aware that certain infections, including gonorrhea, must be reported by law to public health agencies. Partner notification will also take place, but methods vary.

CN: Management of care; CL: Apply

70. 2. National advisory committees on immunization practices review vaccination evidence and update recommendations yearly. Current vaccination catch-up schedules are readily available on their Web sites. The lack of vaccinations is a strong indicator that the child probably does not have an **HCP** . Even if the client had a provider, however, that person might be difficult to reach on a weekend during the time frame of a vaccination clinic. If consulted, the pharmacist would most likely have to review the latest guidelines that are equally available to the nurse. Reading each of manufacturer's inserts for multiple vaccines would be time consuming, and synthesis of the information could possibly lead to errors.

CN: Management of care; CL: Apply

71. 2. Any unusual event that occurs after the administration of a vaccination should be reported through an immunization surveillance system, especially if it happens within 1 month of the vaccine administration. In the United States, it is the Vaccine Adverse Event Reporting System (VAERS). In Canada, it is Canadian Adverse Events Following Immunization Surveillance System (CAEFISS). A high fever, with or without a seizure, that occurs within 6 weeks of vaccination may have been caused by the vaccine. A febrile seizure is considered a moderate reaction that warrants caution with future chickenpox vaccination. A single febrile seizure does not require

referral to a neurologist.

CN: Safety and infection control; CL: Synthesize

72. 4. An adolescent's body is undergoing rapid changes. Adolescence is a time of integrating these rapidly occurring physical changes into the self-concept to achieve the developmental task of a positive self-identity. Thus, most adolescents spend much time worrying about their personal appearance. This behavior is not abnormal narcissism, a method of procrastination, or a way of testing the parents' limits.

CN: Health promotion and maintenance; CL: Analyze

73. 3. An open-ended question is apt to supply more information when a person is under stress and easily susceptible to being influenced by the question. The other questions are direct and only require an answer with limited information.

CN Management of care; CL: Analyze

TEST

2

The Child with Respiratory Health Problems

- The Client with Tonsillitis
- The Client with Otitis Media
- The Client with Foreign Body Aspiration
- The Client with Asthma
- The Client with Cystic Fibrosis and Bronchopneumonia
- The Client with Sudden Infant Death Syndrome
- The Client Who Requires Immediate Care and Cardiopulmonary Resuscitation
- The Client with Croup
- The Client with Bronchiolitis or Pharyngitis
- Managing Care, Quality, and Safety of Children with Respiratory Health Problems
- Answers, Rationales, and Test-Taking Strategies

The Client with Tonsillitis

- 1.** The nurse is inspecting the child's throat (see figure). The nurse should:

- ☐ 1. remove the tongue blade from the child's hands after he has experienced what it feels like in his mouth.
- ☐ 2. ask the child to hold the tongue blade with both hands in his lap while the nurse uses another tongue blade.
- ☐ 3. have the parent hold the child with arms restrained.
- ☐ 4. guide the tongue blade while the child is holding it to depress the tongue to visualize the throat.

2. The nurse has identified a problem of anxiety for a 4-year-old preparing for a tonsillectomy. The nurse should tell the child:

- ☐ 1. "You will not have so many sore throats after your tonsils are removed."
- ☐ 2. "The doctor will put you to sleep so you do not feel anything."
- ☐ 3. "Show me how to give the doll an IV."
- ☐ 4. "When it is done, you will get to see your mommy and get an ice pop."

3. After a tonsillectomy and adenoidectomy, which finding should alert the nurse to suspect early hemorrhage in a 5-year-old child?

- ☐ 1. drooling of bright red secretions
- ☐ 2. pulse rate of 95 bpm
- ☐ 3. vomiting of 25 mL of dark brown emesis
- ☐ 4. blood pressure of 95/56 mm Hg

4. The nurse is offering nutritional instruction to the parents of a preschooler who has undergone a tonsillectomy and adenoidectomy. What food choice by the parents would indicate successful teaching?

- ☐ 1. meat loaf and uncooked carrots
- ☐ 2. pork and noodle casserole
- ☐ 3. cream of chicken soup and orange sherbet
- ☐ 4. hot dog and potato chips

5. A nurse is teaching the parents of a preschooler about the possibility of postoperative hemorrhage after a tonsillectomy and adenoidectomy. When should the nurse explain that the risk of bleeding is the **greatest**?

- ☐ 1. 1 to 3 days after surgery
- ☐ 2. 4 to 6 days after surgery
- ☐ 3. 7 to 10 days after surgery
- ☐ 4. 11 to 14 days after surgery

The Client with Otitis Media

6. An adolescent female is prescribed amoxicillin for an ear infection. The nurse should teach the adolescent about the risks associated with her concurrent use of:

- ☐ 1. OTC antihistamines.
- ☐ 2. oral contraceptives.
- ☐ 3. multiple vitamins.
- ☐ 4. ibuprofen.

7. A toddler is scheduled to have tympanostomy tubes inserted. When approaching the toddler for the first time, which should the nurse do?

- ☐ 1. Talk to the mother first so that the toddler can get used to the new person.
- ☐ 2. Hold the toddler so that the toddler becomes more comfortable.
- ☐ 3. Walk over and pick the toddler up right away so that the mother can relax.
- ☐ 4. Pick up the toddler and take the child to the play area so that the mother can rest.

8. After insertion of bilateral tympanostomy tubes in a toddler, which instructions should the nurse include in the child's discharge plan for the parents?

- ☐ 1. Insert ear plugs into the canals when the child bathes.
- ☐ 2. Gently clean the ear canal with cotton swabs.
- ☐ 3. Administer the prescribed antibiotic while the tubes are in place.
- ☐ 4. Disregard any drainage from the ear after 1 week.

9. The nurse caring for a 3-year-old with otitis media notes that the client has an allergy to amoxicillin that causes wheezing. Which prescription should the nurse question?

- ☐ 1. azithromycin
- ☐ 2. cephalexin
- ☐ 3. trimethoprim-sulfamethoxazole
- ☐ 4. cefdinir

The Client with Foreign Body Aspiration

10. After teaching the parents of a toddler about commonly aspirated foods, which food, if identified by the parents as easily aspirated, would indicate the need for additional teaching?

- ☐ 1. popcorn
- ☐ 2. raw vegetables
- ☐ 3. round candy
- ☐ 4. crackers

11. A toddler who has been treated for a foreign body aspiration begins to fuss and cry when the parents attempt to leave the hospital for an hour. As the

nurse tries to take the child out of the crib, the child pushes the nurse away. The nurse interprets this behavior as indicating which stage of separation anxiety?

- ☐ 1. protest
- ☐ 2. despair
- ☐ 3. regression
- ☐ 4. detachment

12. The nurse teaches the three cardinal signs of choking to the parents of a toddler who was treated for a foreign body obstruction. When asked to repeat the signs, the parents identify “turn blue” and “cannot speak.” What third sign would the parents identify if teaching was successful?

- ☐ 1. vomits
- ☐ 2. gasps
- ☐ 3. gags
- ☐ 4. collapses

13. The father of a 2-year-old phones the emergency department on a Sunday evening and informs the nurse that his son put a bead in his nose. What is the **most** appropriate recommendation made by the nurse?

- ☐ 1. “Try to remove the bead at home as soon as possible; you might try using a pair of tweezers.”
- ☐ 2. “Be sure to take your child to the pediatrician in the morning so the pediatrician can remove the bead in the office.”
- ☐ 3. “You should bring your child to the emergency department tonight so the bead can be removed as soon as possible.”
- ☐ 4. “Ask your child to blow his nose several times; this should dislodge the bead.”

The Client with Asthma

14. An 11-year-old is admitted for treatment of an asthma attack. Which finding indicates immediate intervention is needed?

- ☐ 1. thin, copious mucous secretions
- ☐ 2. productive cough

- ☐ 3. intercostal retractions
- ☐ 4. respiratory rate of 20 breaths/min

15. A 12-year-old with asthma wants to exercise. Which activity should the nurse suggest to improve breathing?

- ☐ 1. soccer
- ☐ 2. swimming
- ☐ 3. track
- ☐ 4. gymnastics

16. When preparing the teaching plan for the mother of a child with asthma, what information should the nurse include as a sign to alert the mother that her child is having an asthma attack?

- ☐ 1. secretion of thin, copious mucus
- ☐ 2. tight, productive cough
- ☐ 3. wheezing on expiration
- ☐ 4. temperature of 99.4°F (37.4°C)

17. Which assessment findings should lead the nurse to suspect that a toddler is experiencing respiratory distress? Select all that apply.

- ☐ 1. coughing
- ☐ 2. respiratory rate of 35 breaths/min
- ☐ 3. heart rate of 95 beats/min
- ☐ 4. restlessness
- ☐ 5. malaise
- ☐ 6. diaphoresis

18. A child, who uses an inhaled bronchodilator only when needed for asthma, has a best peak expiratory flow rate of 270 L/min. The child's current peak flow reading is 180 L/min. How does the nurse interpret this reading?

- ☐ 1. The child's asthma is under good control, so the routine treatment plan should continue.
- ☐ 2. The child needs to use short-acting, inhaled beta₂-agonist medication.
- ☐ 3. This is a medical emergency requiring a trip to the emergency department for treatment.

- ☐ 4. The child needs to use inhaled cromolyn sodium.

19. An adolescent with chest pain goes to the nurse. The nurse determines that the teenager has a history of asthma but has had no problems for years. What should the nurse do **next**?

- ☐ 1. Call the adolescent's parent.
- ☐ 2. Have the adolescent lie down for 30 minutes.
- ☐ 3. Obtain a peak flow reading.
- ☐ 4. Have the teen take two puffs of his or her short-acting bronchodilator.

20. A 7-year-old child with a history of asthma controlled without medications is referred to the school nurse by the teacher because of persistent coughing. What should the nurse do **first**?

- ☐ 1. Obtain the child's heart rate.
- ☐ 2. Give the child a nebulizer treatment.
- ☐ 3. Call a parent to obtain more information.
- ☐ 4. Have a parent come and pick up the child.

21. When developing a teaching plan for the parent of an asthmatic child concerning measures to reduce allergic triggers, which suggestion should the nurse include?

- ☐ 1. Keep the humidity in the home between 50% and 60%.
- ☐ 2. Have the child sleep in the bottom bunk bed.
- ☐ 3. Use a scented room deodorizer to keep the room fresh.
- ☐ 4. Vacuum the carpet once or twice a week.

22. After discussing asthma as a chronic condition, which statement by the parent of a child with asthma **best** reflects the family's positive adjustment to this aspect of the child's disease?

- ☐ 1. "We try to keep him happy at all costs; otherwise, he has an asthma attack."
- ☐ 2. "We keep our child away from other children to help cut down on infections."
- ☐ 3. "Although our child's disease is serious, we try not to let it be the focus of our family."
- ☐ 4. "I'm afraid that when my child gets older, he will not be able to care

for himself like I do.”

23. A child with asthma states, “I want to play some sports like my friends. What can I do?” The nurse responds to the child based on the understanding of which information?

- ☐ **1.** Physical activities are inappropriate for children with asthma.
- ☐ **2.** Children with asthma must be excluded from team sports.
- ☐ **3.** Vigorous physical exercise frequently precipitates an asthmatic episode.
- ☐ **4.** Most children with asthma can participate in sports if the asthma is controlled.

The Client with Cystic Fibrosis and Bronchopneumonia

24. A child with cystic fibrosis does not like taking a pancreatic enzyme supplement with meals and snacks. The parent does not like to force the child to take the supplement. The **most** important reason for the child to take the pancreatic enzyme supplement with meals and snacks is:

- ☐ **1.** the child will become dehydrated if the supplement is not taken with meals and snacks.
- ☐ **2.** the child needs these pancreatic enzymes to help the digestive system absorb fats, carbohydrates, and proteins.
- ☐ **3.** the child needs the pancreatic enzymes to aid in liquefying mucus to keep the lungs clear.
- ☐ **4.** the child will experience severe diarrhea if the supplement is not taken as prescribed.

25. An adolescent with cystic fibrosis has been hospitalized several times. On the latest admission, the client has labored respirations, fatigue, malnutrition, and failure to thrive. Which initial nursing actions are **most** important?

- ☐ **1.** placing the client on bed rest and obtaining a prescription for a blood gas analysis
- ☐ **2.** implementing a high-calorie, high-protein, low-fat, vitamin-enriched diet and pancreatic granules
- ☐ **3.** applying an oximeter and initiating respiratory therapy

- ☐ 4. inserting an IV line and initiating antibiotic therapy

26. A child with cystic fibrosis is receiving gentamicin. Which nursing action is **most** important?

- ☐ 1. monitoring intake and output
- ☐ 2. obtaining daily weights
- ☐ 3. monitoring the client for indications of constipation
- ☐ 4. obtaining stool samples for hemocult testing

27. When developing the plan of care for a child with cystic fibrosis (CF) who is scheduled to receive postural drainage, the nurse should anticipate performing postural drainage at which times?

- ☐ 1. after meals
- ☐ 2. before meals
- ☐ 3. after rest periods
- ☐ 4. before inhalation treatments

28. What type of diet should the nurse teach the parents to give an older infant with cystic fibrosis (CF)?

- ☐ 1. low-protein diet
- ☐ 2. high-fat diet
- ☐ 3. low-carbohydrate diet
- ☐ 4. high-calorie diet

29. At a follow-up appointment after being hospitalized, an adolescent with a history of cystic fibrosis (CF) describes his stools to the nurse. Which description should the nurse interpret as indicative of continued problems with malabsorption?

- ☐ 1. soft with little odor
- ☐ 2. large and foul-smelling
- ☐ 3. loose with bits of food
- ☐ 4. hard with streaks of blood

30. What toy should the nurse include as part of a recreational therapy plan of care for a 3-year-old child hospitalized with pneumonia and cystic fibrosis?

- ☐ 1. 100-piece jigsaw puzzle
- ☐ 2. child's favorite doll
- ☐ 3. fuzzy stuffed animal
- ☐ 4. scissors, paper, and paste

31. Which factor, if described by the parents of a child with cystic fibrosis (CF), indicates understanding the underlying problem of the disease?

- ☐ 1. an abnormality in the body's mucus-secreting glands
- ☐ 2. formation of fibrous cysts in various body organs
- ☐ 3. failure of the pancreatic ducts to develop properly
- ☐ 4. reaction to the formation of antibodies against streptococcus

32. Which outcome criterion would the nurse develop for a child with cystic fibrosis who has ineffective airway clearance related to increased pulmonary secretions and inability to expectorate?

- ☐ 1. respiratory rate and rhythm within expected range
- ☐ 2. absence of chills and fever
- ☐ 3. ability to engage in age-related activities
- ☐ 4. ability to tolerate usual diet without vomiting

33. A school-age child with cystic fibrosis asks the nurse what sports she can become involved in as she becomes older. Which activity would be appropriate for the nurse to suggest?

- ☐ 1. swimming
- ☐ 2. track
- ☐ 3. baseball
- ☐ 4. soccer

The Client with Sudden Infant Death Syndrome

34. When explaining to parents how to reduce the risk of sudden infant death syndrome (SIDS), the nurse should teach about which measures? Select all that apply.

- ☐ 1. Maintain a smoke-free environment.
- ☐ 2. Use a wedge for side-lying positions.

- ☐ 3. Breast-feed the baby.
- ☐ 4. Place the baby on his or her back to sleep.
- ☐ 5. Use bumper pads over the bed rails.
- ☐ 6. Have the baby sleep in the parent's bed.

35. Which child is **most** at risk for sudden infant death syndrome (SIDS)?

- ☐ 1. infant who is 3 months old
- ☐ 2. 2-year-old who has apnea lasting up to 5 seconds
- ☐ 3. firstborn child whose parents are in their early forties
- ☐ 4. 6-month-old who has had two bouts of pneumonia

36. Parents bring their infant to the emergency department because the child has stopped breathing. A nurse obtains a brief history of events occurring before and after the parents found the infant not breathing. Which question should the nurse ask the parents **first**?

- ☐ 1. "Was the infant sleeping while wrapped in a blanket?"
- ☐ 2. "Was the infant lying on his stomach?"
- ☐ 3. "What did the infant look like when you found him?"
- ☐ 4. "When had you last checked on the infant?"

37. When planning a visit to the parents of an infant who died of sudden infant death syndrome (SIDS) at home, the nurse should visit the parents at which time?

- ☐ 1. a few days after the funeral
- ☐ 2. 2 weeks after the funeral
- ☐ 3. as soon as the parents are ready to talk
- ☐ 4. as soon after the infant's death as possible

The Client Who Requires Immediate Care and Cardiopulmonary Resuscitation

38. A child has just ingested about 10 adult-strength acetaminophen tablets an hour ago. The mother brings the child to the emergency department. What should the nurse do? Place the interventions in the order of priority from first to last. All options must be used.

1. Administer activated charcoal.

2. Assess the airway.

3. Check serum acetaminophen levels.

4. Administer acetylcysteine.

39. On finding a child who is not breathing, the nurse has someone activate the emergency medical system and then does what **first**?

- ☐ 1. Clear the airway.
- ☐ 2. Begin mouth-to-mouth resuscitation.
- ☐ 3. Initiate oxygen therapy.
- ☐ 4. Start chest compressions.

40. Which breathing rates should the nurse use when performing rescue breathing during cardiopulmonary resuscitation for a 5-year-old?

- ☐ 1. 10 breaths/min
- ☐ 2. 12 breaths/min
- ☐ 3. 15 breaths/min
- ☐ 4. 20 breaths/min

41. The nurse begins CPR on a 5-year-old unresponsive client. When the emergency response team arrives, the child continues to have no respiratory effort but has a heart rate of 50 with cyanotic legs. What should the team do **next**?

- ☐ 1. Discontinue compressions, but continue administering breaths with a bag-mask device.
- ☐ 2. Establish an intravenous line with a large bore needle while preparing the defibrillator.
- ☐ 3. Begin 2-person CPR at a ratio of 2 breaths to 15 compressions.
- ☐ 4. Begin 2-person CPR at a ratio of 2 breaths to 30 compressions.

42. As part of a health education program, the nurse teaches a group of parents CPR. The nurse determines that the teaching had been effective when a parent states:

- ☐ 1. "If I am by myself, I should call for help before starting CPR."
- ☐ 2. "I should compress a child's chest using 2 to 3 fingers."
- ☐ 3. "I should deliver chest compression at a rate of 100 per minute."
- ☐ 4. "If I cannot get the breaths to make the chest rise, I should administer abdominal thrusts."

43. When performing cardiopulmonary resuscitation (CPR), which finding indicates that external chest compressions are effective?

- ☐ 1. mottling of the skin
- ☐ 2. pupillary dilation
- ☐ 3. palpable pulse
- ☐ 4. cool, dry skin

44. A nurse walks into the room just as a 10-month-old infant places an object in his mouth and starts to choke. After opening the infant's mouth, which should the nurse do **next** to clear the airway?

- ☐ 1. Use blind finger sweeps.
- ☐ 2. Deliver back slaps and chest thrusts.
- ☐ 3. Apply four subdiaphragmatic abdominal thrusts.
- ☐ 4. Attempt to visualize the object.

45. A young child has had a cardiac arrest, and the rapid response team has been paged. The nurse arrives in the client's room and observes a licensed practical/vocational nurse (LPN/VN) administering CPR to an infant (see figure). To assist the LPN/VN with CPR, the nurse should:

- ☐ 1. take over rescue breaths with a rate of 1 breath per 5 compressions using a bag-mask device while the LPN/VN continues compressions.
- ☐ 2. take over compressions using one hand while the LPN/VN uses a mask device to administer rescue breaths.
- ☐ 3. take over rescue breaths using a rate of 2 breaths per 15 compressions using a bag-mask device while the LPN/VN delivers compressions.
- ☐ 4. take over compressions at 80 compressions a minute while the LPN/VN uses a bag-mask device to administer rescue breaths.

46. When teaching the parents of an infant how to perform back slaps to dislodge a foreign body, what should the nurse tell the parents to use to deliver the blows?

- ☐ 1. palm of the hand
- ☐ 2. heel of the hand
- ☐ 3. fingertips
- ☐ 4. entire hand

47. While the nurse is delivering abdominal thrusts to a 6-year-old who is choking on a foreign body, the child begins to cry. What should the nurse do

next?

- ☐ 1. Tap or gently shake the shoulders.
- ☐ 2. Deliver back slaps.
- ☐ 3. Perform a blind finger sweep of the mouth.
- ☐ 4. Observe the child closely.

The Client with Croup

48. A 3-year-old is brought into the emergency department in her parent's arms. The child's mouth is open, and she is drooling and lethargic. The parent states that the child became ill suddenly within the past 2 hours. What should the nurse do **first**?

- ☐ 1. Draw blood cultures for complete blood count.
- ☐ 2. Start an intravenous line.
- ☐ 3. Inspect the child's throat with a tongue blade.
- ☐ 4. Maintain the child in an undisturbed, upright position.

49. The parent of a 16-month-old child calls the clinic because the child has a low-grade fever, cold symptoms, and a hoarse cough. What should the nurse suggest that the parent do?

- ☐ 1. Offer extra fluids frequently.
- ☐ 2. Bring the child to the clinic immediately.
- ☐ 3. Count the child's respiratory rate.
- ☐ 4. Use a hot air vaporizer.

50. A 21-month-old child admitted with the diagnosis of croup now has a respiratory rate of 48 breaths/min, a heart rate of 120 bpm, and a temperature of 100.8°F (38.2°C) rectally. The nurse is having difficulty calming the child. What should the nurse do **next**?

- ☐ 1. Administer acetaminophen.
- ☐ 2. Notify the healthcare provider (HCP) immediately.
- ☐ 3. Allow the toddler to continue to cry.
- ☐ 4. Offer clear fluids every few minutes.

The Client with Bronchiolitis or Pharyngitis

51. A child has viral pharyngitis. What should the nurse advise the parents to do? Select all that apply.

- ☐ 1. Use a cool mist vaporizer.
- ☐ 2. Offer a soft-to-liquid diet.
- ☐ 3. Administer amoxicillin.
- ☐ 4. Administer acetaminophen.
- ☐ 5. Place the child on secretion precautions.

52. A parent brings a 3-month-old infant to the clinic, reporting that the infant has a cold, is having trouble breathing, and “just does not seem to be acting right.” Which action should the nurse take **first**?

- ☐ 1. Check the infant’s heart rate.
- ☐ 2. Weigh the infant.
- ☐ 3. Assess the infant’s oxygen saturation.
- ☐ 4. Obtain more information from the parent.

53. A nurse’s assessment of a 6-month-old infant reveals a respiratory rate of 52 breaths/min, retractions, and wheezing. The mother states that her infant was doing fine until yesterday. Which action would be **most** appropriate?

- ☐ 1. Administer a nebulizer treatment.
- ☐ 2. Send the infant for a chest radiograph.
- ☐ 3. Refer the infant to the emergency department.
- ☐ 4. Provide teaching about cold care to the mother.

54. An infant is being treated at home for bronchiolitis. What should the nurse teach the parent about home care? Select all that apply.

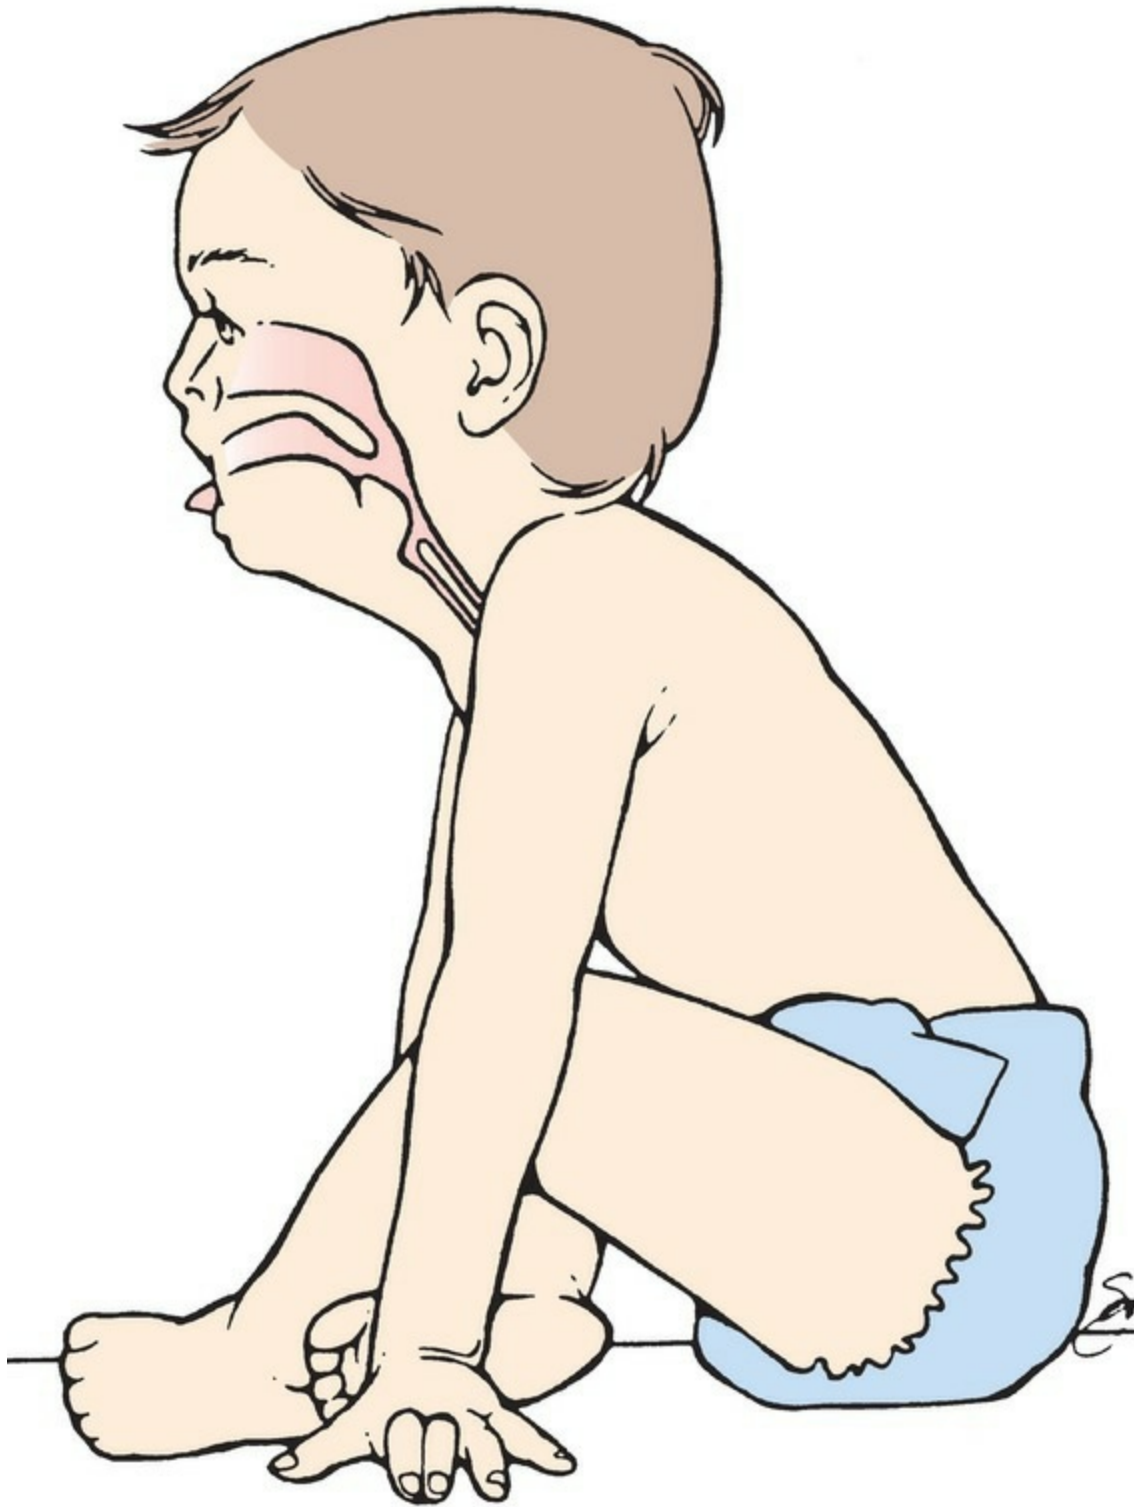

- ☐ 1. offering small amounts of fluids frequently
- ☐ 2. allowing the infant to sleep prone
- ☐ 3. calling the clinic if the infant vomits
- ☐ 4. writing down how much the infant drinks
- ☐ 5. performing chest physiotherapy every 4 hours
- ☐ 6. watching for difficulty breathing

55. In preparation for discharge, the nurse teaches the mother of an infant

diagnosed with bronchiolitis about the condition and its treatment. Which statement by the mother indicates successful teaching?

- ☐ 1. "I need to be sure to take my child's temperature every day."
- ☐ 2. "I hope I do not get a cold from my child."
- ☐ 3. "Next time my child gets a cold I need to listen to the chest."
- ☐ 4. "I need to wash my hands more often."

56. The nurse observes an 18-month-old who has been admitted with a respiratory tract infection who is drooling (see figure). The nurse should **first**:

- ☐ 1. position the child supine.
- ☐ 2. call the rapid response team.
- ☐ 3. suction the airway.

- ☐ 4. administer oxygen.

57. A teaching care plan to prevent the transmission of respiratory syncytial virus (RSV) should include what information? Select all that apply.

- ☐ 1. The virus can be spread by direct contact.
- ☐ 2. The virus can be spread by indirect contact.
- ☐ 3. Palivizumab is recommended to prevent RSV for all toddlers in day care.
- ☐ 4. The virus is typically contagious for 3 weeks.
- ☐ 5. Older children seldom spread RSV.
- ☐ 6. Frequent handwashing helps reduce the spread of RSV.

Managing Care, Quality, and Safety of Children with Respiratory Health Problems

58. A charge nurse is making assignments for a group of children on a pediatric unit. The nurse should **most** avoid assigning the same nurse to care for a 2-year-old with respiratory syncytial virus (RSV) and:

- ☐ 1. an 18-month-old with RSV.
- ☐ 2. a 9-year-old 8 hours postappendectomy.
- ☐ 3. a 1-year-old with a heart defect.
- ☐ 4. a 6-year-old with sickle cell crisis.

59. The nurse is preparing to administer the last dose of ceftriaxone before discharge to a 1-year-old but finds the IV has occluded. The nurse should:

- ☐ 1. restart the IV.
- ☐ 2. administer the medication intramuscularly.
- ☐ 3. document that the last dose was withheld.
- ☐ 4. contact the prescriber to request a prescription change.

60. A nurse administers cefazolin instead of ceftriaxone to an 8-year-old with pneumonia. The client has suffered no adverse effects. The nurse tells the charge nurse of the incident but fears disciplinary action from reporting the error. The charge nurse should tell the nurse:

- ☐ 1. "If you do not report the error, I will have to."

- ☐ 2. “Reporting the error helps to identify system problems to improve client safety.”
- ☐ 3. “Notify the client’s healthcare provider to see if she wants this reported.”
- ☐ 4. “This is not a serious mistake, so reporting it will not affect your position.”

61. A 12-year-old with cystic fibrosis is being treated in the hospital for pneumonia. The healthcare provider (HCP) is calling in a telephone prescription for ampicillin. The nurse should take which actions? Select all that apply.

- ☐ 1. Ask the unit clerk to listen on the speakerphone with the nurse and write down the prescription.
- ☐ 2. Ask the HCP to come to the hospital and write the prescription on the medical record.
- ☐ 3. Repeat the prescription to the HCP.
- ☐ 4. Ask the HCP to confirm that the prescription is correct as understood by the nurse.
- ☐ 5. Ask the nursing supervisor to cosign the telephone prescription as transcribed by the nurse.

62. The triage nurse in the emergency department must prioritize the children waiting to be seen. Which child is in the **greatest** need of emergency medical treatment?

- ☐ 1. a 6-year-old with a fever of 104°F (40°C), a muffled voice, no spontaneous cough, and drooling
- ☐ 2. a 3-year-old with a fever of 100°F (37.8°C), a barky cough, and mild intercostal retractions
- ☐ 3. a 4-year-old with a fever of 101°F (38.3°C), a hoarse cough, inspiratory stridor, and restlessness
- ☐ 4. a 13-year-old with a fever of 104°F (40°C), chills, and a cough with thick yellow secretions

63. A 6-month-old on the pediatric floor has a respiratory rate of 68, mild intercostal retractions, and oxygen saturation of 89%. The infant has not been feeding well for the last 24 hours and is restless. Using the situation,

background, assessment, and recommendation (SBAR) technique for communication, the nurse calls the healthcare provider (HCP) with the recommendation for:

- ☐ 1. starting oxygen.
- ☐ 2. providing sedation.
- ☐ 3. transferring to pediatric intensive care.
- ☐ 4. prescribing a chest CT scan.

64. A child with cystic fibrosis has been admitted to the pediatric unit. What type of diet should the nurse request for the client?

- ☐ 1. high-fat, high-carbohydrate
- ☐ 2. high-calorie, high-protein
- ☐ 3. high-calorie, high-carbohydrate
- ☐ 4. high-carbohydrate, high-protein

Answers, Rationales, and Test-Taking Strategies

*The answers and rationales for each question follow below, along with keys () to the client need (CN) and cognitive level (CL) for each question. In addition, you will also see a glossary icon () highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 12–23 and pages 35–36 in Part 1 of this book.*

The Client with Tonsillitis

1. 4. If the child does not stick out his tongue so the nurse can visualize the throat, it is appropriate to use a tongue blade. Having the child participate by holding the tongue blade while the nurse guides it to facilitate visualization of the throat is appropriate technique. It is not useful to remove the tongue blade or have the child hold it because the nurse will need to use the tongue blade to depress the tongue. It is preferable to engage the child's cooperation before

asking the parent to restrain the child.

CN: Health promotion and maintenance; CL: Apply

2. 4. When preparing a child for a procedure the nurse should use neutral words, focus on sensory experiences, and emphasize the positive aspects at the end. Being reunited with parents and having an ice pop would be considered pleasurable events. Children this age fear bodily harm. To reduce anxiety, the nurse should use the word “fixed” instead of “removed” to describe what is being done to the tonsils. Using the terms “put to sleep” and “IV” may be threatening. Additionally, directing a play experience to focus on IV insertion may be counterproductive as the child may have little recollection of this aspect of the procedure.

CN: Psychosocial integrity; CL: Synthesize

3. 1. After a tonsillectomy and adenoidectomy, drooling bright red blood is considered an early sign of hemorrhage. Often, because of discomfort in the throat, children tend to avoid swallowing; instead, they drool. Frequent swallowing would also be an indication of hemorrhage because the child attempts to clear the airway of blood by swallowing. Secretions may be slightly blood-tinged because of a small amount of oozing after surgery. However, bright red secretions indicate bleeding. A pulse rate of 95 bpm is within the normal range for a 5-year-old child, as is a blood pressure of 95/56 mm Hg. A small amount of blood that is partially digested, and therefore dark brown, is often present in postoperative emesis.

CN: Reduction of risk potential; CL: Analyze

4. 3. For the first few days after a tonsillectomy and adenoidectomy, liquids and soft foods are best tolerated by the child while the throat is sore. Children typically do not chew their food thoroughly, and solid foods are to be avoided because they are difficult to swallow. Although meat loaf would be considered a soft food, uncooked carrots would not be. Pork is frequently difficult to chew. Foods that have sharp edges, such as potato chips, are contraindicated because they are hard to chew and may cause more throat discomfort.

CN: Basic care and comfort; CL: Evaluate

5. 3. The risk of hemorrhage from a tonsillectomy is greatest when the tissue begins sloughing and the scabs fall off. This typically happens 7 to 10 days after a tonsillectomy.

CN: Safety and infection control; CL: Apply

The Client with Otitis Media

6. 2. When a person is taking amoxicillin as well as an oral contraceptive, it renders the contraceptive less effective. Because pregnancy can occur in such a situation, the nurse should advise the client to use additional means of birth control during the time she is taking the antibiotic. There are no risks associated with the concurrent use of amoxicillin and OTC antihistamines, vitamins, or ibuprofen.

CN: Psychosocial integrity; CL: Apply

7. 1. Toddlers should be approached slowly because they are wary of strangers and need time to get used to someone they do not know. The best approach is to ignore them initially and to focus on talking to the parents. The child will likely resist being held by a stranger, so the nurse should not pick up or hold the child until the child indicates a readiness to be approached or the mother indicates that it is okay.

CN: Health promotion and maintenance; CL: Synthesize

8. 1. Placing ear plugs in the ears will prevent contaminated bathwater from entering the middle ear through the tympanostomy tube and causing an infection. Inserting cotton swabs into the ear canal is not recommended. It is not necessary to administer antibiotics continuously to a child with a tympanostomy tube. Antibiotics are appropriate only when an ear infection is present. Drainage from the ear may be a sign of middle ear infection and should be reported to the **healthcare provider (HCP)** 📖.

CN: Reduction of risk potential; CL: Create

9. 2. Cephalexin is a first-generation cephalosporin. Because clients with a history of anaphylaxis to penicillin, or related antibiotics, have an increased risk of having a cross-reaction to first-generation cephalosporin, the nurse should question a prescription for cephalexin. Azithromycin is not usually

considered to be a first-line antibiotic for ear infections in pediatric clients but is effective in pediatric clients with an allergy to amoxicillin. Trimethoprim-sulfamethoxazole is effective against middle ear infections and can be used effectively in pediatric clients with an allergy to amoxicillin. Second- and third-generation cephalosporins, like cefdinir, do not have the same rates of cross-sensitivities to penicillins as first-generation cephalosporin and may be prescribed for pediatric clients with an allergy to amoxicillin.

CN: Management of care; CL: Synthesize

The Client with Foreign Body Aspiration

10. 4. Crackers, because they crumble and easily dissolve, are not commonly aspirated. Because children commonly eat popcorn hulls or pieces that have not popped, popcorn can be easily aspirated. Toddlers frequently do not chew their food well, making raw vegetables a commonly aspirated food. Round candy is often difficult to chew and comes in large pieces, making it easily aspirated.

CN: Health promotion and maintenance; CL: Evaluate

11. 1. Young children have specific reactions to separation and hospitalization. In the protest stage, the toddler physically and verbally attacks anyone who attempts to provide care. Here, the child is fussing and crying and visibly pushes the nurse away. In the despair stage, the toddler becomes withdrawn and obviously depressed (e.g., not engaging in play activities and sleeping more than usual). Regression is a return to a developmentally earlier phase because of stress or crisis (e.g., a toddler who could feed himself before this event is not doing so now). Denial or detachment occurs if the toddler's stay in the hospital without the parent is prolonged because the toddler settles in to the hospital life and denies the parents' existence (e.g., not reacting when the parents come to visit).

CN: Psychosocial integrity; CL: Analyze

12. 4. The three cardinal signs indicating that a child is truly choking and requires immediate lifesaving interventions include inability to speak, blue color (cyanosis), and collapse. Vomiting does not occur while a child is unable to breathe. Once the object is dislodged, however, vomiting may

occur. Gasping, a sudden intake of air, indicates that the child is still able to inhale. When a child is choking, air is not being exchanged, so gagging will not occur.

CN: Reduction of risk potential; CL: Evaluate

13. 3. The bead should be removed by a healthcare professional as soon as possible to prevent the risk of aspiration and tissue necrosis. Unskilled individuals should not attempt to remove an object from the nose as they may push the object further increasing the risk for aspiration. Two-year-old children are not skilled at blowing their nose and may breathe in, further increasing the risk of aspiration.

CN: Management of care; CL: Analyze

The Client with Asthma

14. 3. Intercostal retractions indicate an increase in respiratory effort, which is a sign of respiratory distress. During an asthma attack, secretions are thick, the cough is tight, and respiration is difficult (and shortness of breath may occur). If mucous secretions are copious but thin, the client can expectorate them, which indicates an improvement in the condition. If the cough is productive, it means the bronchospasms and the inflammation have been resolved to the extent that the mucus can be expectorated. A respiratory rate of 20 breaths/min would be considered normal and no intervention would be needed.

CN: Physiological adaptation; CL: Analyze

15. 2. Swimming is appropriate for this child because it requires controlled breathing, assists in maintaining cardiac health, enhances skeletal muscle strength, and promotes ventilation and perfusion. Stop-and-start activities, such as soccer, track, and gymnastics, commonly trigger symptoms in asthmatic clients.

CN: Health promotion and maintenance; CL: Synthesize

16. 3. The child who is experiencing an asthma attack typically demonstrates wheezing on expiration initially. This results from air moving through narrowed airways secondary to bronchoconstriction. The child's

expiratory phase is normally longer than the inspiratory phase. Expiration is passive as the diaphragm relaxes. During an asthma attack, secretions are thick and are not usually expelled until the bronchioles are more relaxed. At the beginning of an asthma attack, the cough will be tight but not productive. Fever is not always present unless there is an infection that may have triggered the attack.

CN: Physiological adaptation; CL: Analyze

17. 1,2,4,6. Coughing, especially at night and in the absence of an infection, is a common symptom of asthma. Early signs of respiratory distress include restlessness, tachypnea, tachycardia, and diaphoresis. Other signs also include hypertension, nasal flaring, grunting, wheezing, and intercostal retractions. A heart rate of 95 bpm is normal for a toddler. Malaise typically does not indicate respiratory distress.

CN: Physiological adaptation; CL: Analyze

18. 2. The peak flow of 180 L/min is in the yellow zone, or 50% to 80% of the child's personal best. This means that the child's asthma is not well controlled, thereby necessitating the use of a short-acting beta₂-agonist medication to relieve the bronchospasm. A peak flow reading greater than 80% of the child's personal best (in this case, 220 L/min or better) would indicate that the child's asthma is in the green zone or under good control. A peak flow reading in the red zone, or less than 50% of the child's personal best (135 L/min or less), would require notification of the **healthcare provider (HCP)**  or a trip to the emergency department. Cromolyn sodium is not used for short-term treatment of acute bronchospasm. It is used as part of a long-term therapy regimen to help desensitize mast cells and thereby help to prevent symptoms.

CN: Reduction of risk potential; CL: Evaluate

19. 3. Problems of chest pain in children and adolescents are rarely cardiac. With a history of asthma, the most likely cause of the chest pain is related to the asthma. Therefore, the nurse should check the adolescent's peak flow reading to evaluate the status of the airflow. Calling the adolescent's parent would be appropriate, but this would be done after the nurse obtains the peak flow reading and additional assessment data. Having the adolescent

lie down may be an option, but more data need to be collected to help establish a possible cause. Because the adolescent has not experienced any asthma problems for a long time, it would be inappropriate for the nurse to administer a short-acting bronchodilator at this time.

CN: Reduction of risk potential; CL: Synthesize

20. 3. Because persistent coughing may indicate an asthma attack and a 7-year-old child would be able to provide only minimal history information, it would be important to obtain information from the parent. Although determining the child's heart rate is an important part of the assessment, it would be done after the history is obtained. More information needs to be obtained before giving the child a nebulizer treatment. Although it may be necessary for the parent to come and pick up the child, a thorough assessment including history information should be obtained first.

CN: Reduction of risk potential; CL: Synthesize

21. 1. To help reduce allergic triggers in the home, the nurse should recommend that the humidity level be kept between 50% and 60%. Doing so keeps the air moist and comfortable for breathing. When air is dry, the risk for respiratory infections increases. Too high a level of humidity increases the risk for mold growth. Typically, the child with asthma should sleep in the top bunk bed to minimize the risk of exposure to dust mites. The risk of exposure to dust mites increases when the child sleeps in the bottom bunk bed because dust mites fall from the top bed, settling in the bottom bed. Scented sprays should be avoided because they may trigger an asthmatic episode. Ideally, carpeting should be avoided in the home if the child has asthma. However, if it is present, carpeting in the child's room should be vacuumed often, possibly daily, to remove dust mites and dust particles.

CN: Reduction of risk potential; CL: Create

22. 3. Positive adjustment to a chronic condition requires placing the child's illness in its proper perspective. Children with asthma need to be treated as normally as possible within the scope of the limitations imposed by the illness. They also need to learn how to manage exacerbations and then resume as normal a life as possible. Trying to keep the child happy at all costs is inappropriate and can lead to the child's never learning how to accept

responsibility for behavior and get along with others. Although minimizing the child's risk for exposure to infections is important, the child needs to be with his or her peers to ensure appropriate growth and development. Children with a chronic illness need to be involved in their care so that they can learn to manage it. Some parents tend to overprotect their child with a chronic illness. This overprotectiveness may cause a child to have an exaggerated feeling of importance or later, as an adolescent, to rebel against the overprotectiveness and the parents.

CN: Psychosocial integrity; CL: Evaluate

23. 4. Physical activities are beneficial to asthmatic children, physically and psychosocially. Most children with asthma can engage in school and sports activities that are geared to the child's condition and within the limits imposed by the disease. The coach and other team members need to be aware of the child's condition and know what to do in case an attack occurs. Those children who have exercise-induced asthma usually use a short-acting bronchodilator before exercising.

CN: Health promotion and maintenance; CL: Apply

The Client with Cystic Fibrosis and Bronchopneumonia

24. 2. The child must take the pancreatic enzyme supplement with meals and snacks to help absorb nutrients so he can grow and develop normally. In cystic fibrosis, the normally liquid mucus is tenacious and blocks three digestive enzymes from entering the duodenum and digesting essential nutrients. Without the supplemental pancreatic enzyme, the child will have voluminous, foul, fatty stools due to the undigested nutrients and may experience developmental delays due to malnutrition. Dehydration is not a problem related to cystic fibrosis. The pancreatic enzymes have no effect on the viscosity of the tenacious mucus. Diarrhea is not caused by failing to take the pancreatic enzyme supplement.

CN: Pharmacological and parenteral therapies; CL: Apply

25. 3. Clients with cystic fibrosis commonly die from respiratory problems. The mucus in the lungs is tenacious and difficult to expel, leading to lung infections and interference with oxygen and carbon dioxide exchange.

The client will likely need supplemental oxygen and respiratory treatments to maintain adequate gas exchange, as identified by the oximeter reading. The child will be on bed rest due to respiratory distress. However, although blood gases will probably be prescribed, the oximeter readings will be used to determine oxygen deficit and are, therefore, more of a priority. A diet high in calories, proteins, and vitamins with pancreatic granules added to all foods ingested will increase nutrient absorption and help the malnutrition; however, this intervention is not the priority at this time. Inserting an IV to administer antibiotics is important and can be done after ensuring adequate respiratory function.

CN: Physiological adaptation; CL: Synthesize

26. 1. Monitoring intake and output is the most important nursing action when administering an aminoglycoside, such as gentamicin, because a decrease in output is an early sign of renal damage. Daily weight monitoring is not indicated when the client is receiving an aminoglycoside. Constipation and bleeding are not adverse effects of aminoglycosides.

CN: Pharmacological and parenteral therapies; CL: Synthesize

27. 2. Postural drainage, which aids in mobilizing the thick, tenacious secretions commonly associated with CF, is usually performed before meals to avoid the possibility of vomiting or regurgitating food. Although the child with CF needs frequent rest periods, this is not an important factor in scheduling postural drainage. However, the nurse would not want to interrupt the child's rest period to perform the treatment. Inhalation treatments are usually given before postural drainage to help loosen secretions.

CN: Reduction of risk potential; CL: Apply

28. 4. CF affects the exocrine glands. Mucus is thick and tenacious, sticking to the walls of the pancreatic and bile ducts and eventually causing obstruction. Because of the difficulty with digestion and absorption, a high-calorie, high-protein, high-carbohydrate, moderate-fat diet is indicated.

CN: Physiological adaptation; CL: Apply

29. 2. In children with CF, poor digestion and absorption of foods, especially fats, results in frequent bowel movements that are bulky, large, and

foul-smelling. The stools also contain abnormally large quantities of fat, which is called *steatorrhea*. An adolescent experiencing good control of the disease would describe soft stools with little odor. Stool described as loose with bits of food indicates diarrhea. Stool described as hard with streaks of blood may indicate constipation.

CN: Physiological adaptation; CL: Analyze

30. 2. The child's favorite doll would be a good choice of toys. The doll provides support and is familiar to the child. Although a 3-year-old may enjoy puzzles, a 100-piece jigsaw puzzle is too complicated for an ill 3-year-old child. In view of the child's lung pathology, a fuzzy stuffed animal would not be advised because of its potential as a reservoir for dust and bacteria, possibly predisposing the child to additional respiratory problems. Scissors, paper, and paste are not appropriate for a 3-year-old unless the child is supervised closely.

CN: Health promotion and maintenance; CL: Create

31. 1. CF is characterized by a dysfunction in the body's mucus-producing exocrine glands. The mucus secretions are thick and sticky rather than thin and slippery. The mucus obstructs the bronchi, bronchioles, and pancreatic ducts. Mucus plugs in the pancreatic ducts can prevent pancreatic digestive enzymes from reaching the small intestine, resulting in poor digestion and poor absorption of various food nutrients. Fibrous cysts do not form in various organs. Cystic fibrosis is an autosomal recessive inherited disorder and does not involve any reaction to the formation of antibodies against streptococcus.

CN: Physiological adaptation; CL: Evaluate

32. 1. After treatment, the client outcome would be that respiratory status would be within normal limits, as evidenced by a respiratory rate and rhythm within expected range. Absence of chills and fever, although related to an underlying problem causing the respiratory problem (e.g., the infection), does not specifically relate to the respiratory problem of ineffective airway clearance. The child's ability to engage in age-related activities may provide some evidence of improved respiratory status. However, this outcome criterion is more directly related to activity intolerance. Although the child's

ability to tolerate his or her usual diet may indirectly relate to respiratory function, this outcome is more specifically related to an imbalanced nutrition that may or may not be related to the child's respiratory status.

CN: Physiological adaptation; CL: Evaluate

33. 1. Swimming would be the most appropriate suggestion because it coordinates breathing and movement of all muscle groups and can be done on an individual basis or as a team sport. Because track events, baseball, and soccer throwing usually are performed outdoors, the child would be breathing in large amounts of dust and dirt, which would be irritating to her mucous membranes and pulmonary system. The strenuous activity and increased energy expenditure associated with track events, in conjunction with the dust and possible heat, would play a role in placing the child at risk for an upper respiratory tract infection and compromising her respiratory function.

CN: Health promotion and maintenance; CL: Synthesize

The Client with Sudden Infant Death Syndrome

34. 1,3,4. Exposure to environmental tobacco increases the risk for SIDS. Sleeping on the back and breast-feeding both decrease the risk of SIDS. The side-lying position is not recommended for sleep. It is recommended that babies be dressed in sleepers and that cribs are free of blankets, pillows, bumper pads, and stuffed animals. Cobedding with parents is not recommended as parents may roll on the child.

CN: Safety and infection control; CL: Create

35. 1. The highest incidence of SIDS occurs in infants between ages 2 and 4 months. About 90% of SIDS occurs before the age of 6 months. Apnea lasting longer than 20 seconds has also been associated with a higher incidence of SIDS. SIDS occurs with higher frequency in families where a child in the family has already died of SIDS, but the age of the parents has not been shown to contribute to SIDS. A respiratory infection such as pneumonia has not been shown to cause a higher incidence of SIDS.

CN: Health promotion and maintenance; CL: Analyze

36. 3. Because this is an especially disturbing and upsetting time for the

parents, they must be approached in a sensitive manner. Asking what the infant looked like when found allows the parents to verbalize what they saw and felt, thereby helping to minimize their feelings of guilt without implying any blame, neglect, wrongdoing, or abuse. Asking if the child was wrapped in a blanket or lying on his stomach, or when the parents last checked on the infant, implies that the parents did something wrong or failed in their care of the infant, thus blaming them for the event.

CN: Physiological adaptation; CL: Analyze

37. 4. The community health nurse should visit as soon after the death as possible because the parents may need help to deal with the sudden, unexpected death of their infant. Parents often have a great deal of guilt in these situations and need to express their feelings to someone who can provide counseling.

CN: Psychosocial integrity; CL: Synthesize

The Client Who Requires Immediate Care and Cardiopulmonary Resuscitation

38. 2,1,3,4. Care of children with an acetaminophen overdose is based on time of ingestion. Immediate care of the child is to ensure airway, breathing, and circulation. If it has been less than 4 hours since ingestion, activated charcoal should be given. Acetaminophen levels should be drawn at 4 hours post ingestion. Depending on the findings, acetylcysteine may also be used as an antidote.

CN: Safety and infection control; CL: Synthesize

39. 4. The current CPR guidelines call for a CAB approach. When breathlessness is determined, the priority nursing action is checking a pulse and beginning compressions. After 30 compressions, the nurse opens the airway and gives 2 breaths. Oxygen therapy would not be initiated at this time because the child is not breathing. Also, administering oxygen therapy would interfere with providing mouth-to-mouth resuscitation.

CN: Physiological adaptation; CL: Synthesize

40. 1. Rescue breaths should be delivered slowly at a volume that makes

the chest rise and fall. For a 5-year-old child, the rate is 10 breaths per minute. If the nurse is also administering chest compressions, the rate is 2 breaths for every 30 compressions.

CN: Physiological adaptation; CL: Apply

41. 3. CPR is done on children for heart rate of less than 60 with signs of poor perfusion. Rescuers should use a 15:2 compression to ventilation ratio for 2-rescuer CPR for a child. Breaths without compressions are indicated only for respiratory arrests where the heart rate remains above 60. The AED/defibrillator should be used as soon as it is ready, but rescuers should not discontinue compressions until the device is ready for use. The ratio for 2-person CPR in adults is 30:2.

CN: Physiological adaptation; CL: Synthesize

42. 3. To maintain the best perfusion, it is recommended that compressions be given at a rate of 100 per minute in a ratio of 30 compressions to 2 breaths for 1-rescuer CPR. Children still are more likely to have had a respiratory arrest than a cardiac arrest and are more likely to respond to opening the airway and rescue breaths. Therefore, it is recommended that unless the collapse was witnessed, a sole rescuer should attempt 5 cycles of CPR before leaving to call for help. Using 2 to 3 fingers for chest compressions is recommended for infant CPR only. Abdominal thrusts are no longer recommended for unconscious victims.

CN: Physiological adaptation; CL: Evaluate

43. 3. With CPR, effectiveness of external chest compressions is indicated by palpable peripheral pulses, the disappearance of mottling and cyanosis, the return of pupils to normal size, and warm, dry skin. To determine whether the victim of cardiopulmonary arrest has resumed spontaneous breathing and circulation, chest compressions must be stopped for 5 seconds at the end of the first minute and every few minutes thereafter.

CN: Physiological adaptation; CL: Evaluate

44. 2. The nurse should use mechanical force—back slaps and chest thrusts—in an attempt to dislodge the object. Blind finger sweeps are not appropriate in infants and children because the foreign body may be pushed

back into the airway. Subdiaphragmatic abdominal thrusts are not used for infants aged 1 year or younger because of the risk of injury to abdominal organs. If the object is not visible when opening the mouth, time is wasted in looking for it. Action is required to dislodge the object as quickly as possible.

CN: Reduction of risk potential; CL: Apply

45. 3. The nurse should first obtain a bag-mask device and assist with CPR by giving breaths at 2 breaths/15 compressions. The **LPN/VN**  is using correct technique by using one hand on the chest to administer chest compressions. The heel of both hands is used for older children and adolescents. The compression rate is at least 100/min.

CN: Management of care; CL: Apply

46. 2. Back slaps are delivered rapidly and forcefully with the heel of the hand between the infant's shoulder blades. Slowly delivered back slaps are less likely to dislodge the object. Using the heel of the hand allows more force to be applied than when using the palm or the whole hand, increasing the likelihood of loosening the object. The fingertips would be used to deliver chest compressions to an infant younger than 1 year of age.

CN: Physiological adaptation; CL: Apply

47. 4. Crying indicates that the airway obstruction has been relieved. No additional thrusts are needed. However, the child needs to be observed closely for complications, including respiratory distress. Tapping or shaking the shoulders is used initially to determine unresponsiveness in someone who appears unconscious. Delivering chest or back slaps could jeopardize the child's now-patent airway. Because the obstruction has been relieved, there is no need to sweep the child's mouth. Additionally, blind finger sweeps are contraindicated because the object may be pushed further back, possibly causing a complete airway obstruction.

CN: Physiological adaptation; CL: Synthesize

The Client with Croup

48. 4. This child is in severe respiratory distress with the potential for complete airway obstruction. The nurse should refrain from disturbing the

child at this time to avoid irritating the epiglottis and causing it to completely obstruct the child's airway. The child may be intubated or undergo a tracheotomy. However, initially, the child should be kept as calm as possible with as little disruption as possible. Any attempt to restrain the child, draw blood, insert an IV, or examine her throat could result in total airway obstruction.

CN: Physiological adaptation; CL: Synthesize

49. 1. The toddler is exhibiting cold symptoms. A hoarse cough may be part of the upper respiratory tract infection. The best suggestion is to have the father offer the child additional fluids at frequent intervals to help keep secretions loose and membranes moist. There is no evidence presented to suggest that the child needs to be brought to the clinic immediately. Although having the father count the child's respiratory rate may provide some additional information, it may lead the father to suspect that something is seriously wrong, possibly leading to undue anxiety. A hot air vaporizer is not recommended. However, a cool mist vaporizer would cause vasoconstriction of the respiratory passages, making it easier for the child to breathe and loosening secretions.

CN: Physiological adaptation; CL: Synthesize

50. 2. The nurse may be having difficulty calming the child because the child is experiencing increasing respiratory distress. The normal respiratory rate for a 21-month-old is 25 to 30 breaths/min. The child's respiratory rate is 48 breaths/min. Therefore, the **HCP**  needs to be notified immediately. Typically, acetaminophen is not given to a child unless the temperature is 101°F (38.6°C) or higher. Letting the toddler cry is inappropriate with croup because crying increases respiratory distress. Offering fluids every few minutes to a toddler experiencing increasing respiratory distress would do little, if anything, to calm the child. Also, the child would have difficulty coordinating breathing and swallowing, possibly increasing the risk of aspiration.

CN: Physiological adaptation; CL: Synthesize

The Client with Bronchiolitis or Pharyngitis

51. 1,2,4. Viral pharyngitis is treated with symptomatic, supportive therapy. Treatment includes use of a cool mist vaporizer, feeding a soft or liquid diet, and administration of acetaminophen for comfort. Viral infections do not respond to antibiotic administration. The child does not need to be on secretion precautions because viral pharyngitis is not contagious.

CN: Psychosocial integrity; CL: Synthesize

52. 3. In an infant with these symptoms, the first action by the nurse would be to obtain an oxygen saturation reading to determine how well the infant is oxygenating. Because the parent probably can provide no other information, checking the heart rate would be the second action done by the nurse. Then the nurse would obtain the infant's weight.

CN: Reduction of risk potential; CL: Synthesize

53. 3. Based on the assessment findings of increased respiratory rate, retractions, and wheezing, this infant needs further evaluation, which could be obtained in an emergency department. Without a definitive diagnosis, administering a nebulizer treatment would be outside the nurse's scope of practice unless there was a prescription for such a treatment. Sending the infant for a radiograph may not be in the nurse's scope of practice. The findings need to be reported to an **HCP**  who can then determine whether or not a chest radiograph is warranted. The infant is exhibiting signs and symptoms of respiratory distress and is too ill to send out with just instructions on cold care for the mother.

CN: Physiological adaptation; CL: Synthesize

54. 1,6. An infant with bronchiolitis will have increased respirations and will tire more quickly, so it is best and easiest for the infant to take fluids more often in smaller amounts. The parents also would be instructed to watch for signs of increased difficulty breathing, which signal possible complications. Healthy infants and even those with bronchiolitis should sleep in the supine position. Calling the clinic for an episode of vomiting would not be necessary. However, the parents would be instructed to call if the infant cannot keep down any fluids for a period of more than 4 hours. Parents would not need to record how much the infant drinks. Chest physiotherapy is not indicated because it does not help and further irritates the infant.

CN: Basic care and comfort; CL: Create

55. 4. Handwashing is the best way to prevent respiratory illnesses and the spread of disease. Bronchiolitis, a viral infection primarily affecting the bronchioles, causes swelling and mucus accumulation of the lumina and subsequent hyperinflation of the lung with air trapping. It is transmitted primarily by direct contact with respiratory secretions as a result of eye-to-hand or nose-to-hand contact or from contaminated fomites. Therefore, handwashing minimizes the risk for transmission. Taking the child's temperature is not appropriate in most cases. As long as the child is getting better, taking the temperature will not be helpful. The mother's statement that she hopes she does not get a cold from her child does not indicate understanding of what to do after discharge. For most parents, listening to the child's chest would not be helpful because the parents would not know what they were listening for. Rather, watching for an increased respiratory rate, fever, or evidence of poor eating or drinking would be more helpful in alerting the parent to potential illness.

CN: Physiological adaptation; CL: Evaluate

56. 2. The nurse should suspect epiglottitis in any young child with a respiratory infection who sits leaning forward with an open mouth and protruding tongue and is drooling. Epiglottitis is a medical emergency. The **rapid response team** 📖 should be notified to secure the airway. While waiting for the team, the child should remain sitting upright to facilitate breathing; complete obstruction may occur if the child is placed prone or becomes agitated. Therefore, it is important to avoid any procedures that upset the child such as suctioning or applying oxygen.

CN: Reduction of risk potential; CL: Synthesize

57. 1,2,6. RSV can be spread through direct contact such as kissing the face of an infected person, and it can be spread through indirect contact by touching surfaces covered with infected secretions. Handwashing is one of the best ways to reduce the risk of disease transmission. Palivizumab can prevent severe RSV infections but is only recommended for the most at-risk infants and children. RSV is typically contagious for 3 to 8 days. RSV frequently manifests in older children as cold-like symptoms. Infected

school-age children frequently spread the virus to other family members.

CN: Safety and infection control; CL: Create

Managing Care, Quality, and Safety of Children with Respiratory Health Problems

58. 3. RSV may be spread through both direct and indirect contact. While contact and standard precautions should be employed, a measure to further decrease the risk of nosocomial infections is to avoid assigning the same nurse caring for an RSV client to a client at risk for infection. A private room is preferred, but if this is not an option, the nurse should understand that children 2 years of age and younger are most at risk for RSV, especially if they have other chronic problems such as a heart defect. From an infection control perspective, pairing two clients with RSV is ideal. RSV infections are less likely to pose a serious problem in older children.

CN: Safety and infection control; CL: Synthesize

59. 4. Restarting an IV for one dose of a medication may not be in the infant's best interest when the medication can be given in an alternate form. The prescriber should be contacted to determine IM or PO options. Ceftriaxone may be given IM, but changing the route of a medication administration requires a prescription. While reasons for giving a medication late would be indicated, the failing to complete an entire course of antibiotics contributes to the emergence of antibiotic resistance, and withholding the medicine would rarely be the best option.

CN: Management of care; CL: Synthesize

60. 2. Client safety is enhanced when the emphasis on medication errors is to determine the root cause. All errors should be reported so systems can identify patterns that contribute to errors. Here, the similar names probably contributed to the error. The nurse who commits the error knows all the relevant information and is in the best position to report it. While the **healthcare provider (HCP)**  should be notified, it is a nursing - responsibility to report errors, not an HCP's choice. Relating mistakes to a nurse's position focuses on personal blame.

 CN: Safety and infection control; CL: Synthesize

61. 3,4. To ensure client safety in obtaining telephone prescriptions, the prescription must be received by a **registered nurse (RN)** . The nurse should write the prescription, read the prescription back to the **HCP** , and receive confirmation from the HCP that the prescription is correct. It is not necessary to ask the unit clerk to listen to the prescription, to require the HCP to come to the hospital to write the prescription on the **medical record** , or to have the nursing supervisor cosign the telephone prescription.

 CN: Safety and infection control; CL: Synthesize

62. 1. This child is exhibiting signs and symptoms of epiglottitis, which is a medical emergency due to the risk of complete airway obstruction. The 3- and 4-year-olds are exhibiting signs and symptoms of croup. Symptoms often diminish after the child has been taken out in the cool night air. If symptoms do not improve, the child may need a single dose of dexamethasone. Fever should also be treated with antipyretics. The 13-year-old is exhibiting signs and symptoms of bronchitis. Treatment includes rest, antipyretics, and hydration.

 CN: Management of care; CL: Analyze

63. 1. The infant is experiencing signs and symptoms of respiratory distress indicating the need for oxygen therapy. Sedation will not improve the infant's respiratory distress and would likely cause further respiratory depression. If the infant's respiratory status continues to decline, she may need to be transferred to the pediatric intensive care. Oxygen should be the priority as it may improve the infant's respiratory status. A chest CT is not indicated. However, a CXR would be another appropriate recommendation for this infant.

 CN: Safety and infection control; CL: Apply

64. 2. A high-calorie, high-protein diet is necessary to ensure adequate growth. Some children require up to two times the recommended daily allowance of calories (increased calorie diet includes foods high in fat and balanced carbohydrates). Pancreatic enzyme activity is lost, and malabsorption of fats, proteins, and carbohydrates occurs.

 CN: Management of care; CL: Apply

The Child with Cardiovascular and Hematologic Health Problems

- The Client Undergoing a Cardiac Catheterization
- The Client with a Congenital Heart Defect
- The Client with Rheumatic Fever
- The Client with Kawasaki Disease
- The Client with Sickle Cell Anemia
- The Client with Iron Deficiency Anemia
- The Client with Hemophilia
- The Client with Leukemia
- Managing Care, Quality, and Safety of Children with Cardiovascular and Hematologic Health Problems
- Answers, Rationales, and Test-Taking Strategies

The Client Undergoing a Cardiac Catheterization

1. The nurse caring for a 7-year-old child who has undergone a cardiac catheterization 2 hours ago finds the dressing and bed saturated with blood. The nurse should **first**:

- ☐ **1.** assess the vital signs.
- ☐ **2.** reinforce the dressing.
- ☐ **3.** apply pressure just above the catheter insertion site.
- ☐ **4.** notify the healthcare provider (HCP).

2. A 4-year-old has been scheduled for a cardiac catheterization. To help prepare the family, the nurse should:

- ☐ **1.** advise the family to bring the child to the hospital for a tour a week in

advance.

- ☐ 2. explain that the child will need a large bandage after the procedure.
- ☐ 3. discourage bringing favorite toys that might become associated with pain.
- ☐ 4. explain that the child may get up as soon as the vital signs are stable.

3. When teaching the parents of a child with a ventricular septal defect who is scheduled for a cardiac catheterization, the nurse explains that this procedure involves the use of which technique?

- ☐ 1. ultra-high-frequency sound waves
- ☐ 2. catheter placed in the right femoral vein
- ☐ 3. cutdown procedure to place a catheter
- ☐ 4. general anesthesia

4. When developing the discharge teaching plan for the parents of a child who has undergone a cardiac catheterization for ventricular septal defect, which information should the nurse expect to include?

- ☐ 1. restriction of the child's activities for the next 3 weeks
- ☐ 2. use of sponge baths until the stitches are removed
- ☐ 3. use of prophylactic antibiotics before receiving any dental work
- ☐ 4. maintenance of a pressure dressing until a return visit with the healthcare provider (HCP)

The Client with a Congenital Heart Defect

5. Discharge teaching for a 3-month-old infant with a cardiac defect who is to receive digoxin should include which information? Select all that apply.

- ☐ 1. Give the medication at regular intervals.
- ☐ 2. Mix the medication with a small volume of breast milk or formula.
- ☐ 3. Repeat the dose one time if the child vomits immediately after administration.
- ☐ 4. Notify the healthcare provider (HCP) of poor feeding or vomiting.
- ☐ 5. Make up any missed doses as soon as realized.
- ☐ 6. Notify the HCP if more than two consecutive doses are missed.

6. An 18-month-old with a congenital heart defect is to receive digoxin

twice a day. Which instructions should the nurse give the parents?

- ☐ 1. Digoxin enables the heart to pump more effectively with a slower and more regular rhythm.
- ☐ 2. Signs of toxicity include increased pulse and visual disturbances.
- ☐ 3. Digoxin is absorbed better if taken with meals.
- ☐ 4. If the child vomits within 15 minutes of administration, the dosage should be repeated.

7. Which signs and symptoms would lead the nurse to suspect a child has tetralogy of Fallot (TOF)? Select all that apply.

- ☐ 1. murmur
- ☐ 2. history of squatting
- ☐ 3. bounding pulses
- ☐ 4. cyanosis
- ☐ 5. faint pulse
- ☐ 6. tachypnea

8. The nurse is caring for a newborn with a large ventricular septal defect. The client has undergone pulmonary artery banding. Which assessment findings indicate that the pulmonary artery band is functioning effectively?

- ☐ 1. Capillary refill is less than 3 seconds.
- ☐ 2. Urine output is greater than 1 mL/kg/h.
- ☐ 3. Breath sounds are clear and equal bilaterally.
- ☐ 4. Radial pulses are bounding.

9. A child diagnosed with tetralogy of Fallot becomes upset, cries, and thrashes around when a blood specimen is obtained. The child becomes cyanotic, and the respiratory rate increases to 44 breaths/min. Which action should the nurse do **first**?

- ☐ 1. Obtain a prescription for sedation for the child.
- ☐ 2. Assess for an irregular heart rate and rhythm.
- ☐ 3. Explain to the child that it will only hurt for a short time.
- ☐ 4. Place the child in a knee-to-chest position.

10. When teaching a preschool-age child how to perform coughing and deep-breathing exercises before corrective surgery for tetralogy of Fallot,

which teaching and learning principles should the nurse address **first**?

- ☐ 1. organizing information to be taught in a logical sequence
- ☐ 2. arranging to use actual equipment for demonstrations
- ☐ 3. building the teaching on the child's current level of knowledge
- ☐ 4. presenting the information in order from simplest to most complex

11. When assessing a child after heart surgery to correct tetralogy of Fallot, which finding should alert the nurse to suspect a low cardiac output?

- ☐ 1. bounding pulses and mottled skin
- ☐ 2. altered level of consciousness and thready pulse
- ☐ 3. capillary refill of 2 seconds and blood pressure of 96/67 mm Hg
- ☐ 4. extremities warm to the touch and pale skin

12. Which intervention is the **greatest priority** for the therapeutic management of a child with congestive heart failure (CHF) caused by pulmonary stenosis?

- ☐ 1. educating the family about the signs and symptoms of infection
- ☐ 2. administering enoxaparin to improve left ventricular contractility
- ☐ 3. assessing heart rate and blood pressure every 2 hours
- ☐ 4. administering furosemide to decrease systemic venous congestion

13. An infant weighing 9 kg is in the pediatric intensive care unit following arterial switch surgery. In the past hour, the infant has had 16 mL of urine output. Which action should the nurse take?

- ☐ 1. Notify the healthcare provider (HCP) immediately.
- ☐ 2. Record the urine output in the medical record.
- ☐ 3. Administer a fluid bolus immediately.
- ☐ 4. Assess for other signs of hypervolemia.

14. A child has had open heart surgery to repair a tetralogy of Fallot with a patch. The nurse should instruct the parents to:

- ☐ 1. notify all healthcare providers (HCPs) before invasive procedures for the next 6 months.
- ☐ 2. maintain adequate hydration of at least 10 glasses of water a day.
- ☐ 3. provide for frequent rest periods and naps during the first 4 weeks.

- ☐ 4. restrict the ingestion of bananas and citrus fruit.

15. As part of the preoperative teaching for the family of a child undergoing a tetralogy of Fallot repair, the nurse tells the family upon returning to the pediatric floor that the child may:

- ☐ 1. be placed on a reduced sodium diet.
- ☐ 2. have an activity restriction for several days.
- ☐ 3. be assigned to an isolation room.
- ☐ 4. have visits limited to a select few.

16. After surgery to correct a tetralogy of Fallot, the child's parents express concern to the nurse that their 4-year-old child wants to be held more frequently than usual. The nurse recommends:

- ☐ 1. introducing a new skill.
- ☐ 2. play therapy.
- ☐ 3. encouraging the behavior.
- ☐ 4. having the volunteer hold the child.

17. The parent of a child hospitalized with tetralogy of Fallot tells the nurse that the child's 3-year-old sibling has become quiet and shy and demonstrates more than a usual amount of genital curiosity since this child's hospitalization. The nurse should tell the parent:

- ☐ 1. "This behavior is very typical for a 3-year-old."
- ☐ 2. "This may be how your child expresses feeling a need for attention."
- ☐ 3. "This may be an indication that your child may have been sexually abused."
- ☐ 4. "This may be a sign of depression in your child."

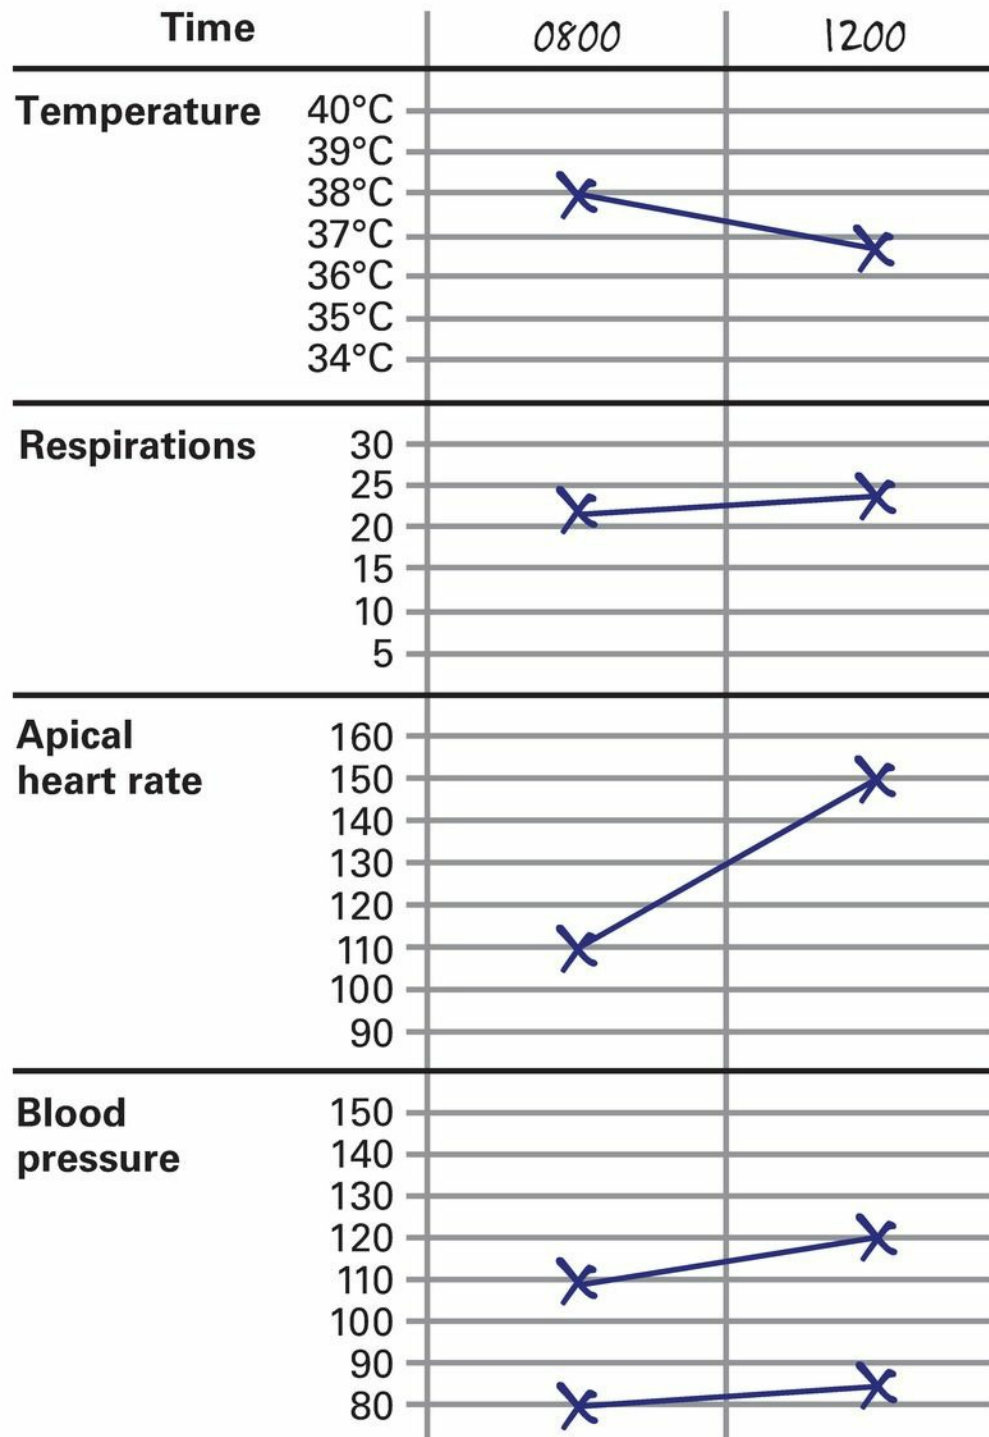

The Client with Rheumatic Fever

18. A 13-year-old has been admitted with a diagnosis of rheumatic fever and is on bed rest. He has a sore throat. His joints are painful and swollen. He has a red rash on his trunk and is experiencing aimless movements of his extremities. Use the chart below to determine what the nurse should do **first**.

- ☐ 1. Report the heart rate to the healthcare provider (HCP).
- ☐ 2. Apply lotion to the rash.

- ☐ 3. Splint the joints to relieve the pain.
- ☐ 4. Request a prescription for medication to treat the elevated temperature.

Vital Signs

19. A nurse is planning care for a 12-year-old with rheumatic fever. The nurse should teach the parents to:

- ☐ 1. observe the child closely.
- ☐ 2. allow the child to participate in activities that will not tire him.
- ☐ 3. provide for adequate periods of rest between activities.
- ☐ 4. encourage someone in the family to be with the child 24 hours a day.

20. A 12-year-old with rheumatic fever has a history of long-term aspirin use. Which client statement **most** indicates that the client is experiencing a serious adverse reaction to aspirin?

- ☐ 1. "I hear ringing in my ears."
- ☐ 2. "I put lotion on my itchy skin."
- ☐ 3. "My stomach hurts after I take that medicine."
- ☐ 4. "These pills make me cough."

21. Which outcome indicates that the activity restriction necessary for a 7-year-old child with rheumatic fever during the acute phase has been effective?

- ☐ 1. Joints demonstrate absence of permanent injury.
- ☐ 2. The resting heart rate is between 60 and 100 bpm.
- ☐ 3. The child exhibits a decrease in chorea movements.
- ☐ 4. The subcutaneous nodules over the joints are no longer palpable.

22. Which initial physical finding indicates the development of carditis in a child with rheumatic fever?

- ☐ 1. heart murmur
- ☐ 2. low blood pressure
- ☐ 3. irregular pulse
- ☐ 4. anterior chest wall pain

23. The healthcare provider (HCP) prescribes pulse assessments through the night for a 12-year-old child with rheumatic fever who has a daytime heart rate of 120 bpm. The nurse explains to the mother that this is to evaluate if the elevated heart rate is caused by:

- ☐ 1. the morning digitalis.

- ☐ 2. normal activity during waking hours.
- ☐ 3. a warmer daytime environment.
- ☐ 4. normal variations in day and evening hours.

24. Which action should the nurse perform to help alleviate a child's joint pain associated with rheumatic fever?

- ☐ 1. Maintain the joints in an extended position.
- ☐ 2. Apply gentle traction to the child's affected joints.
- ☐ 3. Support proper alignment with rolled pillows.
- ☐ 4. Use a bed cradle to avoid the weight of bed linens on joints.

The Client with Kawasaki Disease

25. When developing the plan of care for a newly admitted 2-year-old child with the diagnosis of Kawasaki disease (KD), which intervention should be the **priority**?

- ☐ 1. taking vital signs every 6 hours
- ☐ 2. monitoring intake and output every hour
- ☐ 3. minimizing skin discomfort
- ☐ 4. providing passive range-of-motion exercises

26. A child with Kawasaki disease is receiving low-dose aspirin. The mother calls the clinic and states that the child has been exposed to influenza. Which recommendations should the nurse make? Select all that apply.

- ☐ 1. Increase fluid intake.
- ☐ 2. Stop the aspirin.
- ☐ 3. Keep the child home from school.
- ☐ 4. Watch for fever.
- ☐ 5. Weigh the child daily.

27. A 16-month-old child diagnosed with Kawasaki disease (KD) is very irritable, refuses to eat, and exhibits peeling skin on the hands and feet. What should the nurse do **first**?

- ☐ 1. Apply lotion to the hands and feet.
- ☐ 2. Offer foods the toddler likes.

- ☐ 3. Place the toddler in a quiet environment.
- ☐ 4. Encourage the parents to get some rest.

28. Which information should the nurse include when completing discharge instructions for the parents of a 12-month-old child diagnosed with Kawasaki disease (KD) and being discharged home?

- ☐ 1. Offer the child extra fluids every 2 hours for 2 weeks.
- ☐ 2. Take the child's temperature daily for several days.
- ☐ 3. Check the child's blood pressure daily until the follow-up appointment.
- ☐ 4. Call the healthcare provider (HCP) if the irritability lasts for 2 more weeks.

The Client with Sickle Cell Anemia

29. The nurse is teaching the parents of a child with sickle cell disease. To instruct them on how to prevent sickle cell crisis, the nurse should include which instructions?

- ☐ 1. Exercise in cool temperatures.
- ☐ 2. Drink at least 2 quarts of fluids per day.
- ☐ 3. Avoid contact sports.
- ☐ 4. Take anti-inflammatory medications before exercising.

30. The nurse explains to the parents of a 1-year-old child admitted to the hospital in sickle cell crisis that the local tissue damage the child has on admission is caused by which factor?

- ☐ 1. autoimmune reaction complicated by hypoxia
- ☐ 2. lack of oxygen in the red blood cells
- ☐ 3. obstruction to circulation
- ☐ 4. elevated serum bilirubin concentration

31. The parents of a child with sickle cell disease ask the nurse why their child's hemoglobin was normal at birth but now the child has S hemoglobin. Which response by the nurse is appropriate?

- ☐ 1. "The placenta bars passage of the hemoglobin S from the mother to the fetus."
- ☐ 2. "The red bone marrow does not begin to produce hemoglobin S until

several months after birth.”

- ☐ 3. “Antibodies transmitted from you to the fetus provide the newborn with temporary immunity.”
- ☐ 4. “The newborn has a high concentration of fetal hemoglobin in the blood for some time after birth.”

The Client with Iron Deficiency Anemia

32. Which action indicates that the parents of a 12-month-old with iron deficiency anemia understand how to administer iron supplements? Select all that apply.

- ☐ 1. They administer iron supplements in combination with fruit juice.
- ☐ 2. They administer iron supplements with meals.
- ☐ 3. They report dark stools.
- ☐ 4. They brush the child’s teeth after administering the iron supplements.
- ☐ 5. They decrease dietary intake of foods fortified with iron.

33. A parent asks the nurse if a child’s iron deficiency anemia is related to the child’s frequent infections. The nurse responds based on an understanding of which principle?

- ☐ 1. Little is known about iron deficiency anemia and its relationship to infection in children.
- ☐ 2. Children with iron deficiency anemia are more susceptible to infection than are other children.
- ☐ 3. Children with iron deficiency anemia are less susceptible to infection than are other children.
- ☐ 4. Children with iron deficiency anemia are equally as susceptible to infection as are other children.

34. Which statements by the mother of a toddler should lead the nurse to suspect that the child is at risk for iron deficiency anemia? Select all that apply.

- ☐ 1. “He drinks over four glasses of milk per day.”
- ☐ 2. “I cannot keep enough apple juice in the house; he must drink over 10 oz (300 mL) per day.”

- ☐ 3. "He refuses to eat more than two different kinds of vegetables."
- ☐ 4. "He does not like meat, but he will eat small amounts of it."
- ☐ 5. "He sleeps 12 hours every night and takes a 2-hour nap."

35. Which foods should the nurse encourage a parent to offer to a child with iron deficiency anemia?

- ☐ 1. rice cereal, whole milk, and yellow vegetables
- ☐ 2. potato, peas, and chicken
- ☐ 3. macaroni, cheese, and ham
- ☐ 4. pudding, green vegetables, and rice

The Client with Hemophilia

36. What is the **most** appropriate method to use when drawing blood from a child with hemophilia?

- ☐ 1. Use finger punctures for lab draws.
- ☐ 2. Prepare to administer platelets.
- ☐ 3. Apply heat to the extremity before venipunctures.
- ☐ 4. Schedule all labs to be drawn at one time.

37. A diagnosis of hemophilia A is confirmed in an infant. Which instruction should the nurse provide the parents as the infant becomes more mobile and starts to crawl?

- ☐ 1. Administer one-half of a children's aspirin for a temperature higher than 101°F (38.3°C).
- ☐ 2. Sew thick padding into the elbows and knees of the child's clothing.
- ☐ 3. Check the color of the child's urine every day.
- ☐ 4. Expect the eruption of the primary teeth to produce moderate to severe bleeding.

38. A child with hemophilia presents with a burning sensation in the knee and reluctance to move the body part. The nurse collaborates with the care team to provide factor replacement and:

- ☐ 1. administer an aspirin-containing compound.
- ☐ 2. institute rest, ice, compression, and elevation (RICE).

- ☐ 3. begin physical therapy with active range of motion.
- ☐ 4. initiate skin traction.

39. Because of the risks associated with administration of antihemophilic factor (recombinant), the nurse should teach the child's family to recognize and immediately report which problem?

- ☐ 1. yellowing of the skin
- ☐ 2. constipation
- ☐ 3. abdominal distention
- ☐ 4. hives

40. The mother tells the nurse she will be afraid to allow her child with hemophilia to participate in sports because of the danger of injury and bleeding. After explaining that physical fitness is important for children with hemophilia, which activity should the nurse suggest as ideal?

- ☐ 1. snow skiing
- ☐ 2. swimming
- ☐ 3. basketball
- ☐ 4. gymnastics

The Client with Leukemia

41. A 15-year-old has been admitted to the hospital with the diagnosis of acute lymphocytic leukemia. Which signs and symptoms require the most immediate nursing intervention?

- ☐ 1. fatigue and anorexia
- ☐ 2. fever and petechiae
- ☐ 3. swollen neck lymph glands and lethargy
- ☐ 4. enlarged liver and spleen

42. A 12-year-old with leukemia is receiving cyclophosphamide. The nurse should assess for the adverse effect of:

- ☐ 1. photosensitivity
- ☐ 2. ataxia
- ☐ 3. cystitis

- ☐ 4. cardiac arrhythmias

43. After teaching the parents of a child newly diagnosed with leukemia about the disease, which description if given by the parent **best** indicates understanding the nature of leukemia?

- ☐ 1. “The disease is an infection resulting in increased white blood cell production.”
- ☐ 2. “The disease is a type of cancer characterized by an increase in immature white blood cells.”
- ☐ 3. “The disease is an inflammation associated with enlargement of the lymph nodes.”
- ☐ 4. “The disease is an allergic disorder involving increased circulating antibodies in the blood.”

44. Which problem is the highest risk for a child with leukemia whose lab values are as follows: WBC $6,500 \text{ mm}^3$ ($6.5 \times 10^9/\text{L}$), platelet count $40,000 \mu\text{L}$ ($40 \times 10^9/\text{L}$), and HCT 41.2% (0.412)?

- ☐ 1. activity intolerance
- ☐ 2. bleeding
- ☐ 3. impaired tissue perfusion
- ☐ 4. infection

45. Which statement should the nurse use to describe to the parents why their child with leukemia is at risk for infections?

- ☐ 1. “Abnormal platelets lead to bruising and bleeding.”
- ☐ 2. “There are an insufficient number of circulating white blood cells.”
- ☐ 3. “The number of red blood cells is inadequate for carrying oxygen.”
- ☐ 4. “Immature white blood cells are incapable of handling an infectious process.”

46. Which beverage should the nurse plan to give a child with leukemia to relieve nausea?

- ☐ 1. orange juice
- ☐ 2. weak tea
- ☐ 3. plain water
- ☐ 4. a carbonated beverage

47. Which medication prescription to help relieve pain in a child with leukemia should the nurse question?

- ☐ 1. hydromorphone
- ☐ 2. acetaminophen with codeine
- ☐ 3. ibuprofen
- ☐ 4. acetaminophen with hydrocodone

48. After teaching a child with leukemia about a scheduled bone marrow aspiration, the nurse determines that the teaching has been successful when the child identifies which place as the site for the aspiration?

- ☐ 1. right lateral side of the right wrist
- ☐ 2. middle of the chest
- ☐ 3. distal end of the thigh
- ☐ 4. back of the hipbone

49. The nurse and parents are planning for the discharge of a child with leukemia who is receiving dactinomycin and vincristine. The nurse should teach the parents to:

- ☐ 1. encourage increased fluid intake.
- ☐ 2. keep the child out of the sun.
- ☐ 3. monitor the child's heart rate.
- ☐ 4. observe the child for memory loss.

50. After doing well for a period of time, a child with leukemia develops an overwhelming infection. The child's death is imminent. Which statement offers the nurse the **best** guide in making plans to assist the parents in dealing with their child's imminent death?

- ☐ 1. Knowing that the prognosis is poor helps prepare relatives for the death of children.
- ☐ 2. Relatives are especially grieved when a child does well at first but then declines rapidly.
- ☐ 3. Trust in healthcare personnel is most often destroyed by a death that is considered untimely.
- ☐ 4. It is more difficult for relatives to accept the death of an older child than that of a toddler.

51. A 12-year-old with leukemia will be taking vincristine. The nurse should encourage the child to eat what kind of diet?

- ☐ 1. high-residue
- ☐ 2. low-residue
- ☐ 3. low-fat
- ☐ 4. high-calorie

52. A 10-year-old with leukemia is taking immunosuppressive drugs. To maintain health, the nurse should instruct the child and parents to:

- ☐ 1. continue with immunizations.
- ☐ 2. not receive any live attenuated vaccines.
- ☐ 3. receive vitamin and mineral supplements.
- ☐ 4. stay away from peers.

53. A nurse is teaching the family of an 8-year-old with acute lymphocytic leukemia about appropriate activities. Which recommendation should the nurse make?

- ☐ 1. home schooling
- ☐ 2. restriction from participating in athletic activities
- ☐ 3. avoiding trips to the shopping mall
- ☐ 4. being treated as “normal” as much as possible

54. Which signs and symptoms of leukemia would lead the nurse to suspect the client has thrombocytopenia? Select all that apply.

- ☐ 1. fever
- ☐ 2. petechiae
- ☐ 3. epistaxis
- ☐ 4. anorexia
- ☐ 5. bone pain
- ☐ 6. shortness of breath

Managing Care, Quality, and Safety of Children with Cardiovascular and Hematologic Health Problems

55. A transfusion of packed red blood cells has been prescribed for a 1-

year-old with a sickle cell anemia. The infant has a 25-gauge IV infusing - dextrose with sodium and potassium. Using the situation, background, assessment, and recommendation (SBAR) method of communication, the nurse contacts the healthcare provider (HCP) and recommends:

- ☐ 1. starting a second IV with a 22-gauge catheter to infuse normal saline with the blood.
- ☐ 2. using the existing IV, but changing the fluids to normal saline for the transfusion.
- ☐ 3. replacing the IV with a 22-gauge catheter to infuse the prescribed fluids.
- ☐ 4. starting a second IV with a 25-gauge catheter to infuse normal saline with the transfusion.

56. An infant has been transferred from the ICU to the pediatric floor after undergoing surgery to correct a heart defect. Which tasks can the nurse delegate to the licensed practical/vocational nurse (LPN/VN)? Select all that apply.

- ☐ 1. administering oral medications
- ☐ 2. administering IV morphine
- ☐ 3. obtaining vital signs
- ☐ 4. morning hygiene
- ☐ 5. circulation checks
- ☐ 6. discharge teaching

57. The nurse is assisting with conscious sedation for a 6-year-old undergoing a bone marrow biopsy. The nurse's **most** important responsibility during the procedure is to:

- ☐ 1. administer the topical anesthetic.
- ☐ 2. keep the parents informed.
- ☐ 3. monitor the client.
- ☐ 4. record the procedure.

58. The nurse is transferring a child who has had open heart surgery from the intensive care unit to the pediatric unit. The child's blood pressure has been fluctuating but has been stable during the last 2 hours. The nurse from the pediatric intensive care unit should include which information in the

report to the nurse on the pediatric unit? Select all that apply.

- ☐ 1. medications being used
- ☐ 2. current vital signs
- ☐ 3. potential for blood pressure to drop
- ☐ 4. drip rate for the intravenous infusion
- ☐ 5. time of the most recent dose of pain medication
- ☐ 6. medications given during surgery

59. The nurse is preparing to administer furosemide to a 3-year-old with a heart defect. The nurse verifies the child's identity by checking the arm band and:

- ☐ 1. asking the child to state her name.
- ☐ 2. checking the room number.
- ☐ 3. asking the child to tell her birth date.
- ☐ 4. asking the parent the child's name.

60. A 7-year-old with hemophilia A has fallen and badly bruised his knee. Which intervention should be done **first** when managing the client's hemarthrosis?

- ☐ 1. Use active range of motion to prevent immobility.
- ☐ 2. Apply cold packs to promote vasoconstriction.
- ☐ 3. Apply pressure and immobilize the joint.
- ☐ 4. Notify the healthcare provider (HCP) of the injury.

61. An 8-week-old infant with congenital heart disease is being discharged. What is the **most** important information for the nurse to convey regarding feeding?

- ☐ 1. Allow the infant 1 hour to complete each feeding.
- ☐ 2. Position the infant in an upright position after each feeding.
- ☐ 3. Give feedings per nasogastric tube to conserve energy.
- ☐ 4. Provide a higher calorie formula or fortified breast milk.

Answers, Rationales, and Test-Taking Strategies

The answers and rationales for each question follow below, along with keys (

) to the client need (CN) and cognitive level (CL) for each question. In addition, you will also see a glossary icon () highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 12–23 and pages 35–36 in Part 1 of this book.

The Client Undergoing a Cardiac Catheterization

1. 3. Direct pressure is the first measure that should be used to control bleeding. Taking the vital signs will not control the bleeding. This should be done while another person is being sent to notify the **HCP** . The dressing can be reinforced after the bleeding has been contained.

 CN: Reduction of risk potential; CL: Synthesize

2. 2. The catheter insertion site will be covered with a bandage. This is important for preschool children to know as they are very concerned about bodily harm. The best time to prepare a preschool child for an invasive procedure is the night before. Bringing a favorite toy to the hospital will help decrease the child's anxiety. To prevent bleeding, the child will be expected to keep the extremity straight for 4 to 6 hours after the procedure, either in bed or on the parent's lap.

 CN: Psychosocial integrity; CL: Synthesize

3. 2. In children, cardiac catheterization usually involves a right-sided approach because septal defects permit entry into the left side of the heart. The catheter is usually inserted into the femoral vein through a percutaneous puncture. A cutdown procedure is rarely used. Echocardiography involves the use of ultra-high-frequency sound waves. The catheterization is usually performed under local, not general, anesthesia with sedation.

 CN: Reduction of risk potential; CL: Apply

4. 3. Prophylactic antibiotics are suggested for children with heart defects before dental work is done to reduce the risk of bacterial infection. Typically,

activities are not restricted after a cardiac catheterization. A percutaneous approach is used to insert the catheter, so stitches are not necessary. Showering or bathing is allowed as usual. The pressure dressing will be removed before the child is discharged.

CN: Reduction of risk potential; CL: Create

The Client with a Congenital Heart Defect

5. 1,4,6. To achieve optimal therapeutic levels, digoxin should be given at regular intervals without variation, usually every 12 hours. Vomiting and poor feeding are signs of toxicity. If more than two consecutive doses are missed, interventions may be needed to assure therapeutic drug levels. The medication should not be mixed with any other fluid as refusal may result in inaccurate intake of the medication. Taking makeup doses, or taking the medication at times other than scheduled, may adversely affect serum levels.

CN: Pharmacological and parenteral therapies; CL: Create

6. 1. Digoxin's effect is to slow the rate of the electrical conduction through the heart and increase the strength of the heart's contraction. Signs of toxicity include anorexia and decreased heart rate, not visual changes or increases in heart rate. Digoxin should be taken 1 hour before meals or 2 hours after meals in order to obtain better absorption of the drug. If the child vomits within 15 minutes of administration, the dose should not be repeated because it is not known how much of the medication has been absorbed.

CN: Pharmacological and parenteral therapies; CL: Apply

7. 1,2,4,6. TOF is a heart condition with four defects: pulmonic stenosis, right ventricular hypertrophy, ventricular septal defect, and an overriding aorta. A systolic murmur, cyanosis, and tachypnea are all symptoms of TOF. Toddlers with uncorrected defects instinctively squat (knee-chest position) to decrease the return of systemic venous blood to the heart. Coarctation of the aorta is a narrowing in the descending aorta, obstructing the systemic blood outflow. Infants with severe constriction may present with faint pulse in lower extremities and bounding pulses in upper extremities.

CN: Physiological adaptation; CL: Analyze

8. 3. Pulmonary artery banding is a palliative treatment used in pediatric clients with congenital cardiac defects with increased pulmonary blood flow. The pulmonary artery band reduces excessive pulmonary blood flow and protects the lungs from irreversible damage. When the pulmonary artery band is functioning properly, the lungs should no longer be receiving an increased amount of blood flow, which would be reflected in clear and equal breath sounds. A capillary refill of less than 3 seconds and a urine output greater than 1 mL/kg/h reflect adequate peripheral perfusion. Bounding radial pulses suggest increased pulmonary blood flow.

CN: Physiological adaptation; CL: Evaluate

9. 4. The child is experiencing tet or hypoxic episode. Therefore, the nurse should place the child in a knee-to-chest position. Flexing the legs reduces venous flow of blood from the lower extremities and reduces the volume of blood being shunted through the interventricular septal defect and the overriding aorta in the child with tetralogy of Fallot. As a result, the blood then entering the systemic circulation has higher oxygen content, and dyspnea is reduced. Flexing the legs also increases vascular resistance and pressure in the left ventricle. An infant often assumes a knee-to-chest position in the crib, or the mother learns to put the infant over her shoulder while holding the child in a knee-to-chest position to relieve dyspnea. If this position is ineffective, then the child may need a sedative. Once the child is in the position, the nurse may assess for an irregular heart rate and rhythm. Explaining to the child that it will only hurt for a short time does nothing to alleviate the hypoxia.

CN: Physiological adaptation; CL: Synthesize

10. 3. Before developing any teaching program for a child, the nurse's first step is to assess the child to determine what is already known. Most older preschool children have some understanding of a condition present since birth. However, the child's interest will soon be lost if familiar material is repeated too often. The nurse can then organize the information in a sequence because there are several steps to be demonstrated. These exercises do not require the use of equipment. The nurse should judge the amount and complexity of the information to be provided, based on the child's current knowledge and response to teaching.

 CN: Psychosocial integrity; CL: Synthesize

11. 2. With a low cardiac output and subsequent poor tissue perfusion, signs and symptoms would include pale, cool extremities; cyanosis; weak, thready pulses; delayed capillary refill; and decrease in level of consciousness.

 CN: Physiological adaptation; CL: Analyze

12. 4. Pulmonary stenosis can cause right-sided CHF, resulting in venous congestion. Removing accumulated fluid is a primary goal of treatment in right-sided CHF. Furosemide is used to reduce venous congestion. It is important to educate the family about signs and symptoms of CHF, but treating the client's CHF is the priority. Enoxaparin is an anticoagulant and will not help improve left ventricular contractility. It is important to assess vital signs frequently in the child with CHF, but assessments do not treat the problem.

 CN: Physiological adaptation; CL: Apply

13. 2. Urine output for an infant weighing 9 kg should be 1 mL/kg/h. Sixteen milliliters of urine output is more than adequate for 1 hour, so the nurse should record the output in the **medical record** . There is no reason to notify the **HCP** regarding adequate urine output. The infant has adequate output, so there is no need for a fluid bolus. A fluid bolus could also cause the infant to become fluid overloaded, increasing the workload on the heart. There is no information in the question indicating that the child is hypervolemic.

 CN: Physiological adaptation; CL: Analyze

14. 1. Children who have undergone open heart surgery with a patch are at risk for infection, especially subacute bacterial endocarditis (SBE), for the first 6 months following surgery. The newest evidence-based guidelines suggest that once the patch has epithelialized, these precautions are no longer necessary. Therefore, parents are instructed about SBE precautions including the need to notify providers before invasive procedures so antibiotics can be prescribed for that time period. Having the child drink a very large amount of water may lead to fluid overload. Children gear their rest schedule to their

activities making it unnecessary to schedule frequent rest periods. Bananas and citrus fruit are high in potassium, but there is no evidence provided that the child has an elevated serum potassium requiring restriction.

CN: Physiological adaptation; CL: Synthesize

15. 1. Because of the hemodynamic changes that occur with open heart surgery repair, particularly with septal defects, transient congestive heart failure may develop. Therefore, the child's sodium intake typically is restricted to 2 to 3 g/day. Activity restrictions are inappropriate. Typically, the child is encouraged to walk the halls and unit. Risk for infection after the repair is the same as any postoperative client; therefore, isolation is not necessary. The child may be placed in a room with other children who are not contagious. Visitors are not restricted unless the pediatric unit has restrictive visiting policies.

CN: Physiological adaptation; CL: Synthesize

16. 2. The child is exhibiting regression. During periods of stress, children frequently revert to behaviors that were comforting in earlier developmental stages; play therapy is one way to help the child cope with the stress. Teaching a new skill most likely would add more stress. Parents should be instructed to praise positive behaviors and ignore regressive behaviors rather than calling attention to them through encouragement or discouragement. Having someone else hold the child does not encourage coping with the stress or promoting appropriate development.

CN: Psychosocial integrity; CL: Synthesize

17. 2. According to Erikson, the central psychosocial task of a preschooler is to develop a sense of initiative versus guilt. Any environmental situation may affect the child. In this situation, the sibling is probably feeling less attention from the mother and trying to resolve the conflict in an inappropriate way. Three-year-olds are usually active and outgoing. These behaviors represent a change. Data are not sufficient to suggest the child has been exposed to a sexual experience. Symptoms of depression would include withdrawal and fatigue.

CN: Psychosocial integrity; CL: Synthesize

The Client with Rheumatic Fever

18. 1. The child's heart rate of 150 bpm is significantly above its rate at the time of his admission. The nurse must notify the **HCP** . The increase in heart rate may indicate carditis, a possible complication of rheumatic fever that can cause serious and lifelong effects on the heart. The HCP will intervene with medication and cardiac monitoring. While lotion may provide comfort, the most important action for the nurse is to notify the HCP of the increased heart rate. Splinting will not help the inflammation that is causing the painful joints. The joint pain will migrate and subside with time. The temperature is not elevated at this time and does not require intervention.

 CN: Physiological adaptation; CL: Synthesize

19. 3. The nurse should teach the parents to provide for sufficient periods of rest to decrease the client's cardiac workload. The client's condition does not warrant close observation unless cardiac complications develop. The child's activity level will be based on the results of the sedimentation rate, c-reactive protein, heart rate, and cardiac function. The family does not need to be with the client 24 hours a day unless carditis develops and his condition deteriorates.

 CN: Basic care and comfort; CL: Synthesize

20. 1. Tinnitus is an adverse effect of prolonged aspirin therapy, and the child should be examined by a **healthcare provider (HCP)** for hearing loss. Itchy skin commonly accompanies the rash associated with rheumatic fever, and the nurse can encourage lotion use. The nurse teaches clients to take aspirin with food or milk to avoid abdominal discomfort. The nurse can also address the fact that coughing after ingesting aspirin can be caused by inadequate fluid intake during administration.

 CN: Pharmacological and parenteral therapies; CL: Analyze

21. 2. During the acute phase of rheumatic fever, the heart is inflamed and every effort is made to reduce the work of the heart. Bed rest with limited activity is necessary to prevent heart failure. Therefore, the most reliable indicator that activity restriction has been effective is a resting heart rate between 60 and 100 bpm, normal for a 7-year-old child. No permanent

damage to the joints occurs with rheumatic fever. The chorea movements associated with rheumatic fever are self-limited and usually disappear in 1 to 3 months. They are unrelated to activity restrictions. Subcutaneous nodules that occur over joint surfaces also resolve over time with no treatment. Therefore, they are not appropriate for evaluating the effectiveness of activity restrictions.

 CN: Physiological adaptation; CL: Evaluate

22. 1. In rheumatic fever, the connective tissue of the heart becomes inflamed, leading to carditis. The most common signs of carditis are heart murmurs, tachycardia during rest, cardiac enlargement, and changes in the electrical conductivity of the heart. Heart murmurs are present in about 75% of all clients during the first week of carditis and in 85% of clients by the third week. Signs of carditis do not include hypotension or chest pain. The client may have a rapid pulse, but it is usually not irregular.

 CN: Physiological adaptation; CL: Analyze

23. 2. An above-average pulse rate that is out of proportion to the degree of activity is an early sign of heart failure in a client with rheumatic fever. The sleeping pulse is used to determine whether the mild tachycardia persists during sleep (inactivity) or whether it is a result of daytime activities. The environmental temperature would need to be quite warmer before it could influence the heart rate. Digitalis lowers the heart rate, so the rate would be decreased during the daytime.

 CN: Reduction of risk potential; CL: Analyze

24. 4. For a child with arthritis associated with rheumatic fever, the joints are usually so tender that even the weight of bed linens can cause pain. Use of a bed cradle is recommended to help remove the weight of the linens on painful joints. Joints need to be maintained in good alignment, not positioned in extension, to ensure that they remain functional. Applying gentle traction to the joints is not recommended because traction is usually used to relieve muscle spasms, not typically associated with rheumatic fever. Supporting the body in good alignment and changing the client's position are recommended, but these measures are not likely to relieve pain.

 CN: Basic care and comfort; CL: Synthesize

The Client with Kawasaki Disease

25. 2. Cardiac status must be monitored carefully in the initial phase of KD because the child is at high risk for congestive heart failure (CHF). Therefore, the nurse needs to assess the child frequently for signs of CHF, which would include respiratory distress and decreased urine output. Vital signs would be obtained more often than every 6 hours because of the risk of CHF. Although minimizing skin discomfort would be important, it does not take priority over monitoring the child's hourly intake and output. Passive range-of-motion exercises would be done if the child develops arthritis.

CN: Physiological adaptation; CL: Create

26. 2,4. Aspirin needs to be stopped because of its possible link to Reye syndrome. Additionally, the parents need to watch for signs and symptoms of influenza. Children with influenza frequently present with fever, cold symptoms, and gastrointestinal symptoms. Increasing the child's fluid intake and weighing the child daily are not needed at this time because the child is not displaying signs of influenza. Keeping the child home from school is not necessary because the child is not symptomatic and has already been exposed.

CN: Reduction of risk potential; CL: Synthesize

27. 3. One of the characteristics of children with KD is irritability. They are often inconsolable. Placing the child in a quiet environment may help quiet the child and reduce the workload of the heart. Although peeling of the skin occurs with KD, the child's irritability takes priority over applying lotion to the hands and feet. Children with KD usually are not hungry and do not eat well regardless of what is served. There is no indication that the parents need rest. Additionally, in this situation, the child takes priority over the parents.

CN: Physiological adaptation; CL: Synthesize

28. 2. The child's temperature should be taken daily for several days after discharge because recurrent fever may develop. Offering the child fluids every 2 hours is not necessary. Doing so increases the child's risk for CHF. Checking the child's blood pressure at home usually is not included as part of the discharge instructions because by the time of discharge the child is

considered stable and the risk for cardiac problems is minimal. Most children with KD recover fully. Irritability may last for 2 months after discharge.

CN: Physiological adaptation; CL: Create

The Client with Sickle Cell Anemia

29. 2. Increasing fluid intake and being well hydrated will help prevent cell stasis in the small vessels. Restricting fluids causes stasis of red blood cells and promotes obstruction and increases the chance of sickling with hypoxia and pain to the part that is involved. Clients with sickle cell disease should avoid exercising in cool temperatures or swimming in cold water. While contact sports are not recommended because of bleeding risks, they do not cause sickle crisis. Taking an anti-inflammatory medication before exercising does not prevent sickle cell crisis.

CN: Health promotion and maintenance; CL: Synthesize

30. 3. Characteristic sickle cells tend to cause “log jams” in capillaries. This results in poor circulation to local tissues, leading to ischemia and necrosis. The basic defect in sickle cell disease is an abnormality in the structure of the red blood cells. The erythrocytes are sickle shaped, rough in texture, and rigid. Sickle cell disease is an inherited disease, not an autoimmune reaction. Elevated serum bilirubin concentrations are associated with jaundice, not sickle cell disease.

CN: Physiological adaptation; CL: Apply

31. 4. Sickle cell disease is an inherited disease that is present at birth. However, 60% to 80% of a newborn’s hemoglobin is fetal hemoglobin, which has a structure different from that of hemoglobin S or hemoglobin A. Sickle cell symptoms usually occur about 4 months after birth, when hemoglobin S begins to replace the fetal hemoglobin. The gene for sickle cell disease is transmitted at the time of conception, not passed through the placenta. Some hemoglobin S is produced by the fetus near term. The fetus produces all its own hemoglobin from the earliest production in the first trimester. Passive immunity conferred by maternal antibodies is not related to sickle cell disease, but this transmission of antibodies is important to protect the infant from various infections during early infancy.

 CN: Physiological adaptation; CL: Apply

The Client with Iron Deficiency Anemia

32. 1,4. Parent teaching concerning a child with iron deficiency anemia should include directions about giving iron combined with fruit juice, in divided doses, between meals, and with a dropper for a 12-month-old or through a straw for older toddlers. Iron stains teeth, so brushing the teeth and administering liquid iron through a dropper or straw are necessary to prevent staining the teeth. Iron should not be given with milk, antacids, or tea and should be administered on an empty stomach. Iron will cause the stool to become black or green, which is normal and does not need to be reported. However, light-colored stools indicate the iron is not being absorbed and should be reported.

 CN: Pharmacological and parenteral therapies; CL: Evaluate

33. 2. Children with iron deficiency anemia are more susceptible to infection because of marked decreases in bone marrow functioning with - microcytosis.

 CN: Physiological adaptation; CL: Apply

34. 1,2. Toddlers should have between two and three servings of milk per day and no more than 6 oz (180 mL) of juice per day. If they have more than that, then they are probably not eating enough other foods, including iron-rich foods that have the needed nutrients. Food preferences vary among children. It is acceptable for the child to refuse foods as long as the diet is balanced and contains adequate calories. The child is obtaining a normal amount of sleep.

 CN: Basic care and comfort; CL: Evaluate

35. 2. Potatoes, peas, chicken, green vegetables, and fortified cereal contain significant amounts of iron and therefore would be recommended. Milk and yellow vegetables are not good iron sources. Rice by itself also is not a good source of iron. Macaroni, cheese, and ham are not high in iron. While pudding (made with fortified milk) and green vegetables contain some iron, the better diet has protein and iron from the chicken and potato.

 CN: Basic care and comfort; CL: Apply

The Client with Hemophilia

36. 4. Coordinating labs to minimize sticks reduces trauma and the risk of bleeding. Fingersticks in general are more painful and associated with more bleeding than are venipunctures. In hemophilia, platelets are typically normal. Heat would increase vasodilatation and increase bleeding.

CN: Reduction of risk potential; CL: Apply

37. 2. As the hemophilic infant begins to acquire motor skills, falls and bumps increase that risk of bleeding. Such injuries can be minimized by padding vulnerable joints. Aspirin is contraindicated because of its antiplatelet properties, which increase the infant's risk for bleeding. Because genitourinary bleeding is not a typical problem in children with hemophilia, urine testing is not indicated. Although some bleeding may occur with tooth eruption, it does not normally cause moderate to severe bleeding episodes in children with hemophilia.

CN: Safety and infection control; CL: Synthesize

38. 2. The child is displaying symptoms of bleeding in the joint and factor replacement is indicated. The RICE method is used additionally as a supportive measure to help control the bleeding. Aspirin-containing compounds contribute to bleeding and should never be used to control pain. Physical therapy is instituted after the acute bleeding to prevent further damage. Orthopedic traction is considered in some rare cases during the rehabilitation phase, but not the acute phase.

CN: Physiological adaptation; CL: Synthesize

39. 4. Administration of antihemolytic factor (recombinant) is a biosynthetic preparation of factor VIII that carries the risk of severe allergic reaction. Signs include hives, difficulty breathing, tachycardia, chills, and fever. Originally, factor VIII preparations were derived from large pools of human plasma and carried the risk of hepatitis, but recombinant preparations do not. Antihemolytic factor (recombinant) is not associated with constipation or abdominal distention.

CN: Pharmacological and parenteral therapies; CL: Synthesize

40. 2. Swimming is an ideal activity for a child with hemophilia because it is a noncontact sport. Many noncontact sports and physical activities that do not place excessive strain on joints are also appropriate. Such activities strengthen the muscles surrounding joints and help control bleeding in these areas. Noncontact sports also enhance general mental and physical well-being. Falls and subsequent injury to the child may occur with snow skiing. Basketball is a contact sport and therefore increases the child's risk for injury. Gymnastics is a very strenuous sport. Gymnasts frequently have muscle and joint injuries that result in bleeding episodes.

CN: Health promotion and maintenance; CL: Apply

The Client with Leukemia

41. 2. Fever and petechiae associated with acute lymphocytic leukemia indicate a suppression of normal white blood cells and thrombocytes by the bone marrow and put the client at risk for other infections and bleeding. The nurse should initiate infection control and safety precautions to reduce these risks. Fatigue is a common symptom of leukemia due to red blood cell suppression. Although the client should be told about the need for rest and meal planning, such teaching is not the priority intervention. Swollen glands and lethargy may be uncomfortable, but they do not require immediate intervention. An enlarged liver and spleen do require safety precautions that prevent injury to the abdomen; however, these precautions are not the priority.

CN: Reduction of risk potential; CL: Analyze

42. 3. Cystitis is a potential adverse effect of cyclophosphamide. The client should be monitored for pain on urination. Photosensitivity, ataxia, and cardiac arrhythmias are not adverse effects associated with cyclophosphamide.

CN: Pharmacological and parenteral therapies; CL: Analyze

43. 2. Leukemia is a neoplastic, or cancerous, disorder of blood-forming tissues that is characterized by a proliferation of immature white blood cells. Leukemia is not an infection, inflammation, or allergic disorder.

 CN: Physiological adaptation; CL: Evaluate

44. 2. A normal platelet count is 150,000 to 400,000 μL (150 to $400 \times 10^9/\text{L}$). A platelet count of 40,000 μL ($40 \times 10^9/\text{L}$) is low and puts the child at risk for injury, bruising, and bleeding. Hematocrit of 41.2% (0.41) is normal; therefore, the child will have adequate oxygenation and tissue perfusion. The white blood cell count of 6,500 mm^3 ($6.5 \times 10^9/\text{L}$) is normal; therefore, the child has no increase in risk for infection.

 CN: Reduction of risk potential; CL: Analyze

45. 4. In leukemia, although there is an increased number of immature white blood cells, they are unable to combat infection. Lack of mature white blood cells puts a child with leukemia at risk for infection. The major morbidity and mortality factor associated with leukemia is infection resulting from the presence of granulocytopenia. Decreased red blood cells are not directly caused by infection. While platelets play a role in the body's response to infection, bleeding does not directly cause infections.

 CN: Reduction of risk potential; CL: Apply

46. 4. Carbonated beverages ordinarily are best tolerated when a child feels nauseated. Many children find cola drinks especially easy to tolerate, but noncola beverages are also recommended. Orange juice usually is not tolerated well because of its high acid content. Tea may also be too acidic, and many children do not like tea. Water does not relieve nausea.

 CN: Basic care and comfort; CL: Apply

47. 3. Ibuprofen prolongs bleeding time and is contraindicated in clients with leukemia. Nonnarcotic drugs other than ibuprofen or aspirin, such as acetaminophen, may be prescribed to control pain and may be used in combination with codeine or hydrocodone if pain is more severe. Hydromorphone may also be used for severe pain.

 CN: Pharmacological and parenteral therapies; CL: Synthesize

48. 4. Although bone marrow specimens may be obtained from various sites, the most commonly used site in children is the posterior iliac crest, the back of the hipbone. This area is close to the body's surface but removed

from vital organs. The area is large, so specimens can easily be obtained. For infants, the proximal tibia and the posterior iliac crest are used. The middle of the chest or sternum is the usual site for bone marrow aspiration in an adult. The wrist, chest, and thigh are not sites from which to obtain bone marrow specimens.

CN: Reduction of risk potential; CL: Evaluate

49. 1. Dactinomycin and vincristine both cause nausea and vomiting. Oral fluids are encouraged, and antiemetics are given to prevent dehydration. Avoiding sun exposure is not necessary because photosensitivity is not associated with these drugs. Heart rate changes and memory issues also are not associated with either of these two drugs.

CN: Pharmacological and parenteral therapies; CL: Synthesize

50. 2. It has been found that parents are more grieved when optimism is followed by defeat. The nurse should recognize this when planning various ways to help the parents of a dying child. It is not necessarily true that knowing about a poor prognosis for years helps prepare parents for a child's death. Death is still a shock when it occurs. Trust in healthcare personnel is not necessarily destroyed when a death is untimely if the family views the personnel as having done all that was possible. It is not more difficult for parents to accept the death of an older child than that of a younger child.

CN: Psychosocial integrity; CL: Synthesize

51. 1. Vincristine may cause constipation, so the client should be encouraged to eat a high-residue (fiber) diet. The other diets do not help with constipation that can occur while receiving vincristine.

CN: Pharmacological and parenteral therapies; CL: Apply

52. 2. Children who are immunosuppressed should not receive any live attenuated vaccines. Clients who are immunosuppressed and are given live attenuated vaccines such as measles, mumps, rubella, and oral polio vaccine can develop severe forms of the diseases for which they are being immunized, which can result in death. Inactivated vaccines may be given if necessary, but the client is not able to adequately produce needed antibodies, and it is recommended that immunizations be delayed for 3 months after the

immunosuppressive drugs have been discontinued. Vitamin and mineral supplements are not normally given in conjunction with immunosuppressive drugs. When the client is immunosuppressed, the client should avoid only persons who have an infection.

CN: Health promotion and maintenance; CL: Synthesize

53. 4. Any child with a chronic illness should be treated as normally as possible. Unless the child has severe bone marrow depression, he or she should be allowed to go to school with others and can go to the mall. If the child is in remission, athletic activities are allowed.

CN: Health promotion and maintenance; CL: Synthesize

54. 2,3. Children with acute lymphocytic leukemia have a reduced platelet count (thrombocytopenia), reduced red blood cell count (anemia), and reduced white blood cell count (neutropenia) because of unrestricted proliferation of immature white blood cell. Chemotherapy is used to treat leukemia and contributes to thrombocytopenia, neutropenia, and anemia. Clients with thrombocytopenia are at risk for bleeding. Petechiae (small red or purple spots on the skin) and epistaxis (nose bleeds) are both signs of bleeding. A fever is a result of a decreased white blood cell count. Anorexia and shortness of breath are a result of a decreased red blood cell count. Bone pain is a result of stress on the bone related to the unrestricted proliferation of the leukemic blast cells.

CN: Physiological adaptation; CL: Analyze

Managing Care, Quality, and Safety of Children with Cardiovascular and Hematologic Health Problems

55. 2. The best evidence indicates that a catheter as small as 27 gauge may safely be used for transfusion in children, but blood must be infused with normal saline, not dextrose. A 1-year-old should be able to maintain his or her blood glucose for the 2-hour duration of the infusion without the need for a second IV.

CN: Management of care; CL: Synthesize

56. 1,3,4. The RN's scope of practice includes assessment, planning,

implementing, and evaluation. Only aspects of care implementation may be delegated to the **LPN/VN**, and the exact skills that may be delegated vary by state and institution. In general, LPN/VNs have been trained to perform the tasks of administering oral medications, performing hygiene, and recording the intake and output. LPN/VNs may also take vital signs to gather data, but the nurse must interpret the data. Administering IV morphine requires assessment of the client's respiratory status before, during, and after the procedure. Circulation checks are assessments the RN should complete.

CN: Management of care; CL: Synthesize

57. 3. During conscious sedation, the client may lose protective reflexes, and adequate respiratory and cardiac function may be impaired. At every procedure, there must be one healthcare professional whose sole responsibility is to monitor the client. Topical agents must be given in advance of the procedure to be effective. During the procedure, the nurse would not leave the child to speak with parents. While the procedure would be documented according to the facility's protocols, proper monitoring of the client is the intervention most associated with reducing risks.

CN: Reduction of risk potential; CL: Apply

58. 1,2,3,4,5. The report made when nurses are “handing off” a client from one nursing unit to another must include information about the condition of the client, potential for changes in the client's condition, current medications, and care and services received. It is not necessary to know what medications were given in surgery to provide safe care at this point.

CN: Safety and infection control; CL: Synthesize

59. 4. Safety standards require the use of two identifiers prior to medication administration. A parent can be used as the second identifier. Many young children will only answer to a nickname that does not coincide with the medical identification band or may answer to any name. It is common for children on a pediatric floor to go into each other's rooms. Small children may not know their birth date.

CN: Safety and infection control; CL: Synthesize

60. 3. Application of pressure and immobilization of the affected limb are

the first priority. Pressure is required to stop the bleeding, and immobilization aids in reducing swelling and pain. Active range of motion is recommended after the bleeding is controlled. The application of cold packs can be helpful in diminishing swelling and pain. Cold packs will also promote vasoconstriction, which can help reduce the bleeding. The **healthcare provider (HCP)** should be informed of the bleeding episode after initial measures to control the bleeding are implemented.

CN: Management of care; CL: Synthesize

61. 4. Infants with congenital heart disease often have difficulty feeding and gaining weight. They will tire quickly during the feeding. Most will do well with smaller, more frequent feedings. The infant with a congenital heart defect should not be given more than 20 minutes per feeding. Fortified breast milk or a high-calorie formula will help the infant gain weight and conserve energy. Prolonging the feeding to an hour will merely tire the infant. Positioning the infant in an upright position is recommended for infants with gastrointestinal reflux. Some infants with a congenital heart defect may not consume adequate amounts of calories through breast- or bottle-feeding and may require supplemental feeding through a nasogastric tube; however, nasogastric tube feedings are not necessary for all infants with congenital heart defects.

CN: Management of care; CL: Synthesize

The Child with Health Problems of the Gastrointestinal Tract

- The Client with Cleft Lip and Palate
- The Client with Tracheoesophageal Fistula
- The Client with an Anorectal Anomaly
- The Client with Pyloric Stenosis
- The Client with Intussusception
- The Client with Inguinal Hernia
- The Client with Hirschsprung's Disease
- The Client with Diarrhea, Gastroenteritis, or Dehydration
- The Client with Appendicitis
- Managing Care, Quality, and Safety of Children with Health Problems of the Gastrointestinal Tract
- Answers, Rationales, and Test-Taking Strategies

The Client with Cleft Lip and Palate

1. When developing the plan of care for an infant with a cleft lip before corrective surgery is performed, what should be a **priority**?

- ☐ **1.** maintaining skin integrity in the oral cavity
- ☐ **2.** using techniques to minimize crying
- ☐ **3.** altering the usual method of feeding
- ☐ **4.** preventing the infant from putting fingers in the mouth

2. Which measure would be **most** effective in helping the infant with a cleft lip and palate to retain oral feedings?

- ☐ **1.** Burp the infant at frequent intervals.

- ☐ 2. Feed the infant small amounts at one time.
- ☐ 3. Place the end of the nipple far to the back of the infant's tongue.
- ☐ 4. Maintain the infant in a supine position while feeding.

3. After teaching the parent of an infant who has had a surgical repair for a cleft lip about the use of elbow restraints at home, the nurse determines that the teaching has been successful when the parent makes which statement?

- ☐ 1. "We will keep the restraints on continuously except when checking the skin under them for redness."
- ☐ 2. "We will keep the restraints on during the day while he is awake, but take them off when we put him to bed at night."
- ☐ 3. "After we get home, we will not have to use the restraints because our child does not suck on his hands or fingers."
- ☐ 4. "We will be sure to keep the restraints on all the time until we come to see the care provider for a follow-up visit."

4. The mother of an infant with a cleft lip asks when the repair will be scheduled. What is the nurse's **best** response?

- ☐ 1. at birth
- ☐ 2. during the first 6 months of life
- ☐ 3. after 6 months of age
- ☐ 4. at 1 year of age

5. On the 2nd postoperative day after repair of a cleft palate, what should the nurse use to feed a toddler?

- ☐ 1. cup
- ☐ 2. straw
- ☐ 3. rubber-tipped syringe
- ☐ 4. large-holed nipple

The Client with Tracheoesophageal Fistula

6. The parents report that their 1-day-old is drooling and having choking episodes with excessive amounts of mucus and color changes, especially during feedings. The nurse should contact the healthcare provider (HCP) to further assess the baby and request a prescription for:

- ☐ 1. a lactation consultation.
- ☐ 2. a blood gas.
- ☐ 3. an x-ray with orogastric catheter placement.
- ☐ 4. a serum blood glucose.

7. The parents of a child with a tracheoesophageal fistula express feelings of guilt about their baby's anomaly. Which approach by the nurse would **best** support the parents?

- ☐ 1. helping the parents accept their feelings as a normal reaction
- ☐ 2. explaining that the parents did nothing to cause the newborn's defect
- ☐ 3. encouraging the parents to concentrate on planning their baby's care
- ☐ 4. urging the parents to visit their newborn as often as possible

8. After teaching the parents of a neonate diagnosed with a tracheoesophageal fistula (TEF) about this anomaly, the nurse determines that the teaching was successful when the parent describes the condition in which way?

- ☐ 1. "The muscle below the stomach is too tight, causing the baby to vomit forcefully."
- ☐ 2. "There is a blind upper pouch and an opening from the esophagus into the airway."
- ☐ 3. "The lower bowel is lacking certain nerves to allow normal function."
- ☐ 4. "A part of the bowel is on the outside without anything covering it."

9. Which finding would indicate that an infant with a tracheoesophageal fistula (TEF) needs suctioning?

- ☐ 1. barking cough
- ☐ 2. substernal retractions
- ☐ 3. decreased activity level
- ☐ 4. increased respiratory rate

10. The nurse is administering bolus gastrostomy feedings to an infant after surgery to correct a tracheoesophageal fistula (TEF). To prevent air from entering the stomach once the syringe barrel is attached to the gastrostomy tube the nurse should:

- ☐ 1. unclamp the tube after pouring the complete amount of formula to be

administered into the syringe barrel.

- ☐ 2. pour all of the formula to be administered into the syringe barrel after opening the clamp.
- ☐ 3. maintain a continuous flow of formula down the side of the syringe barrel once the clamp is opened.
- ☐ 4. allow a small amount of formula to enter the stomach before pouring more formula into the syringe barrel.

11. After surgery to repair a tracheoesophageal fistula, an infant receives gastrostomy tube feedings. The nurse continues holding the infant for about 15 minutes after the feeding primarily to help accomplish what need?

- ☐ 1. Promote intestinal peristalsis.
- ☐ 2. Prevent regurgitation of formula.
- ☐ 3. Relieve pressure on the surgical site.
- ☐ 4. Associate eating with a pleasurable experience.

12. A newborn who had a surgical repair of a tracheoesophageal fistula (TEF) is started on oral feedings. What should the nurse include in the teaching plan for the parent about oral feedings?

- ☐ 1. They are better tolerated when larger but less frequent feedings are offered.
- ☐ 2. They should be offered on a feeding schedule to help the infant accept the feedings more readily.
- ☐ 3. They are best accepted by the infant when offered by the same nurse or by the infant's parent.
- ☐ 4. They are best planned in conjunction with observations of the infant's behavior.

The Client with an Anorectal Anomaly

13. After completing diagnostic testing, the surgeon has scheduled a newborn with the diagnosis of an imperforate anus for surgery the next day. The infant's parents are Catholic and do not want the surgery to take place unless the infant has first been baptized. The nurse asks the parents:

- ☐ 1. "Are you worried your baby might die?"

- ☐ 2. "Do you want me to help arrange the baptism?"
- ☐ 3. "Do you want to speak with the social worker?"
- ☐ 4. "Would you prefer to wait for the surgery?"

14. What should the nurse assess in a newborn diagnosed with an anorectal malformation? Select all that apply.

- ☐ 1. abdominal distention
- ☐ 2. loose stools
- ☐ 3. vomiting
- ☐ 4. meconium in the urine
- ☐ 5. meconium stools

15. When performing discharge teaching with the parents of a neonate who has successfully undergone surgery to repair a low anorectal anomaly, which parent statement about the child's prognosis indicates teaching has been successful?

- ☐ 1. "My child will need to wear protective pads until puberty."
- ☐ 2. "My child will need extra fluids to prevent constipation."
- ☐ 3. "My child will probably always need a high-fiber diet."
- ☐ 4. "My child has a good chance of being potty trained."

16. When the infant returns to the unit after imperforate anus repair, the nurse should place the infant in which position?

- ☐ 1. on the abdomen, with legs pulled up under the body
- ☐ 2. on the back, with legs extended straight out
- ☐ 3. lying on the side with the hips elevated
- ☐ 4. lying on the back in a position of comfort

17. The father of a neonate scheduled for gastrointestinal surgery asks the nurse how newborns respond to painful stimuli. What is the nurse's **best** response?

- ☐ 1. "Newborns cry and cannot be distracted to stop crying."
- ☐ 2. "When faced with a pain, newborns try to roll away from it."
- ☐ 3. "Newborns typically move their whole body in response to pain."
- ☐ 4. "Pain causes the newborn to withdraw the affected part."

18. When developing the plan of care for a neonate who was diagnosed with an anorectal malformation and who subsequently underwent surgery, what intervention would be **most** helpful in facilitating parent-infant bonding?

- ☐ 1. explaining to the parents that they can visit at any time
- ☐ 2. encouraging the parents to hold their infant
- ☐ 3. asking the parents to help monitor the infant's intake and output
- ☐ 4. helping the parents plan for their infant's discharge

The Client with Pyloric Stenosis

19. A 4-week-old infant admitted with the diagnosis of hypertrophic pyloric stenosis presents with a history of vomiting. The nurse should anticipate that the infant's vomitus would contain gastric contents and which other body substances?

- ☐ 1. bile and streaks of blood
- ☐ 2. mucus and bile
- ☐ 3. mucus and streaks of blood
- ☐ 4. stool and bile

20. When an infant with pyloric stenosis is admitted to the hospital, which aspect of the plan of care should the nurse implement **first**?

- ☐ 1. Weigh the infant.
- ☐ 2. Begin an intravenous infusion.
- ☐ 3. Switch the infant to an oral electrolyte solution.
- ☐ 4. Orient the mother to the hospital unit.

21. After teaching the parent of an infant with pyloric stenosis about the condition, which cause, if stated by the parent, indicates effective teaching?

- ☐ 1. "An enlarged muscle below the stomach sphincter."
- ☐ 2. "A telescoping of the large bowel into the smaller bowel."
- ☐ 3. "A result of giving the baby more formula than is necessary."
- ☐ 4. "A result of my baby taking the formula too quickly."

22. A newborn admitted with pyloric stenosis is lethargic and has poor

skin turgor. The healthcare provider (HCP) has prescribed IV fluids of dextrose water with sodium and potassium. The baby's admission potassium level is 3.4 mEq/L (3.4 mmol/L). What should the nurse do **first**?

- ☐ 1. Notify the HCP.
- ☐ 2. Administer the prescribed fluids.
- ☐ 3. Verify that the infant has urinated.
- ☐ 4. Have the potassium level redrawn.

23. After undergoing surgical correction of pyloric stenosis, an infant is returned to the room in stable condition. While standing by the crib, the mother says, "Perhaps if I had brought my baby to the hospital sooner, the surgery could have been avoided." What should be the nurse's **best** response?

- ☐ 1. "Surgery is the most effective treatment for pyloric stenosis."
- ☐ 2. "Try not to worry; your baby will be fine."
- ☐ 3. "Do you feel that this problem indicates that you are not a good mother?"
- ☐ 4. "Do you think that earlier hospitalization could have avoided surgery?"

24. After surgery to correct pyloric stenosis, the nurse instructs the parents about the postoperative feeding schedule for their infant. The parents exhibit understanding of these instructions when they state that they can start feeding the child within which time frame?

- ☐ 1. 6 hours
- ☐ 2. 8 hours
- ☐ 3. 10 hours
- ☐ 4. 12 hours

25. Immediately after the first oral feeding after corrective surgery for pyloric stenosis, a 4-week-old infant is fussy and restless. Which action would be **most** appropriate at this time?

- ☐ 1. Encourage the parents to hold the infant.
- ☐ 2. Hang a mobile over the infant's crib.
- ☐ 3. Give the infant more to eat.
- ☐ 4. Give the infant a pacifier to suck on.

26. Which behavior exhibited by the parent of an infant with pyloric

stenosis should the nurse correctly interpret as a positive indication of - parental coping?

- ☐ 1. telling the nurse that they have to get away for a while
- ☐ 2. discussing the infant's care realistically
- ☐ 3. repeatedly asking if their child is normal
- ☐ 4. exhibiting fear that they will disturb the infant

27. A 6-month-old has had a pyloromyotomy to correct a pyloric stenosis. Three days after surgery, the parents have placed their infant in his own infant seat (see figure). What should the nurse do?

- ☐ 1. Reposition the infant to the left side.
- ☐ 2. Ask the parents to put the infant back in his crib.
- ☐ 3. Remind the parents that the infant cannot use a pacifier now.
- ☐ 4. Tell the parents they have positioned their infant correctly.

The Client with Intussusception

28. When assessing a 4-month-old infant diagnosed with possible intussusception, the nurse should expect the parent to relate which information about the infant's crying and episodes of pain?

- ☐ 1. constant accompanied by leg extension
- ☐ 2. intermittent with knees drawn to the chest
- ☐ 3. shrill during ingestion of solids
- ☐ 4. intermittent while being held in the mother's arms

29. When obtaining the nursing history from the mother of an infant with suspected intussusception, which question would be **most** helpful?

- ☐ 1. "What do the stools look like?"
- ☐ 2. "When was the last time your child urinated?"
- ☐ 3. "Is your child eating normally?"
- ☐ 4. "Has your child had any episodes of vomiting?"

30. A nasogastric tube inserted during surgical correction of infant's intussusception is no longer freely removing gastric secretions. What should the nurse do **next**?

- ☐ 1. Aspirate the tube with a syringe.
- ☐ 2. Irrigate the tube with distilled water.
- ☐ 3. Increase the level of suction.
- ☐ 4. Rotate the tube.

31. Which assessment should be the **priority** for an infant who has had surgery to correct an intussusception and is now at risk for development of a paralytic ileus postoperatively?

- ☐ 1. measurement of urine specific gravity
- ☐ 2. auscultation of bowel sounds
- ☐ 3. inspection of the first stool passed
- ☐ 4. measurement of gastric output

32. An infant is to be discharged after surgery for intussusception. In developing the discharge teaching plan, the nurse should tell the parent:

- ☐ 1. the infant will experience a change in the normal home routine.

- ☐ 2. the infant can return to the prehospital routine immediately.
- ☐ 3. the infant needs to ingest more calories at home than what was consumed in the hospital.
- ☐ 4. the infant will continue to experience abdominal cramping for a few days.

The Client with Inguinal Hernia

33. When assessing an infant with suspected inguinal hernia, which finding would be **most** significant?

- ☐ 1. The inguinal swelling is reddened, and the abdomen is distended.
- ☐ 2. The infant is irritable, and a thickened spermatic cord is palpable.
- ☐ 3. The inguinal swelling can be reduced, and the infant has a stool in the diaper.
- ☐ 4. The infant's diaper is wet with urine, and the abdomen is nontender.

34. The healthcare provider (HCP) is able to reduce an infant's hernia and schedules the infant for a herniorrhaphy in 2 days. The parent asks the nurse why the surgery is not being performed now. Which response about delaying the surgery is **most** appropriate?

- ☐ 1. "Delaying the surgery ensures that your infant will receive the proper preoperative preparation."
- ☐ 2. "We need to make sure that your infant receives nothing by mouth for at least 24 hours before the surgery."
- ☐ 3. "Waiting these 2 days helps to allow any edema and inflammation in the area to subside."
- ☐ 4. "Your infant needs to wear a truss for at least 24 hours before any surgery can be attempted."

35. Preoperatively, the nurse develops a plan to prepare a 7-month-old infant psychologically for a scheduled herniorrhaphy the next day. Which intervention should the nurse expect to implement to accomplish this goal?

- ☐ 1. explaining the preoperative and postoperative procedures to the mother
- ☐ 2. having the mother stay with the infant
- ☐ 3. making sure the infant's favorite toy is available

- ☐ 4. allowing the infant to play with surgical equipment

36. Which instruction should the nurse expect to include in the discharge teaching plan for the parent of an infant who has had an inguinal - herniorrhaphy?

- ☐ 1. Change diapers as soon as they become soiled.
- ☐ 2. Apply an abdominal binder.
- ☐ 3. Keep the incision covered with a sterile dressing.
- ☐ 4. Restrain the infant's hands.

37. A parent asks, "How should I bathe my baby now that he has had surgery for his inguinal hernia?" Which instruction should the nurse give the parent?

- ☐ 1. "Clean his face and diaper area for 2 weeks."
- ☐ 2. "Use sterile sponges to cleanse the inguinal incision."
- ☐ 3. "Give him a sponge bath daily for 1 week."
- ☐ 4. "Give the infant full tub baths every day."

The Client with Hirschsprung's Disease

38. During physical assessment of a 4-month-old infant with Hirschsprung's disease, the nurse should **most** likely note which finding?

- ☐ 1. scaphoid-shaped abdomen
- ☐ 2. weight less than expected for height and age
- ☐ 3. cyanosis of the fingers and toes
- ☐ 4. hyperactive deep tendon reflexes

39. An infant diagnosed with Hirschsprung's disease is scheduled to receive a temporary colostomy. When initially discussing the diagnosis and treatment with the parents, which action would be **most** appropriate?

- ☐ 1. assessing the adequacy of their coping skills
- ☐ 2. reassuring them that their child will be fine
- ☐ 3. encouraging them to ask questions
- ☐ 4. giving them printed material on the procedure

40. After teaching the parents of an infant diagnosed with Hirschsprung's

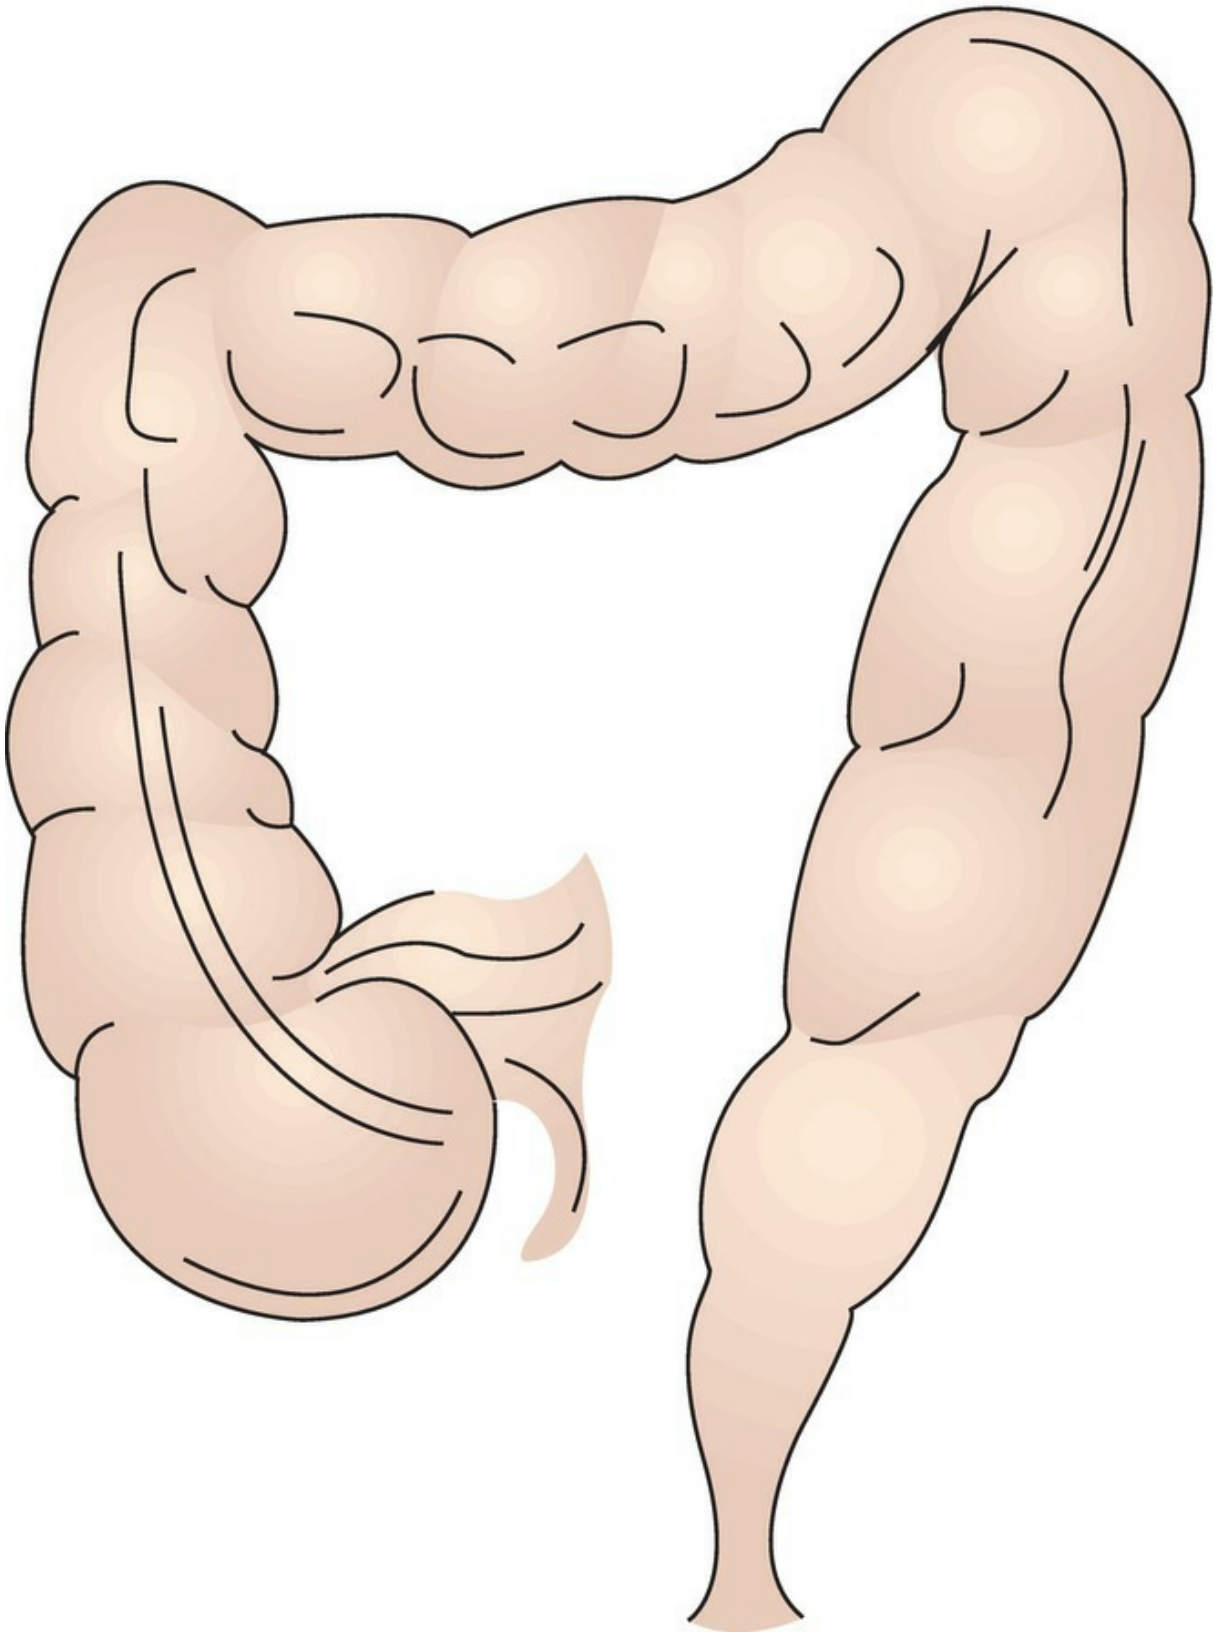

disease, the nurse determines that the parents understand the diagnosis when the parent makes which statement?

- ☐ 1. "There is no rectal opening for stool to pass."
- ☐ 2. "There is a tube between the trachea and esophagus."
- ☐ 3. "The nerves at the end of the large colon are missing."
- ☐ 4. "The muscle below the stomach is too tight."

41. When developing the preoperative plan of care for an infant with Hirschsprung's disease, which intervention should the nurse include?

- ☐ 1. administering a tap water enema
- ☐ 2. inserting a gastrostomy tube
- ☐ 3. restricting oral intake to clear liquids
- ☐ 4. using povidone-iodine solution to prepare the perineum

42. The nurse is showing the parent of a child with Hirschsprung's disease where the aganglionic area is located. Identify the area the nurse should point out as being aganglionic.

43. An infant diagnosed with Hirschsprung's disease undergoes surgery

with the creation of a temporary colostomy. Which statement by the parent regarding the colostomy indicates the need for further teaching?

- ☐ 1. "The colostomy is only temporary."
- ☐ 2. "The colostomy will give time for the nerves to return to normal."
- ☐ 3. "The colostomy may include two separate abdominal openings."
- ☐ 4. "Right after the procedure, the stoma may appear purple."

44. When teaching the mother of an infant who has received a temporary colostomy for treatment of Hirschsprung's disease about how the stoma should normally appear, which description about the stoma's appearance should the nurse include in the teaching?

- ☐ 1. becoming dark brown in 2 months
- ☐ 2. staying deep red in color
- ☐ 3. changing to several shades of pink
- ☐ 4. turning almost purple in color

45. When teaching the parent of an infant with Hirschsprung's disease who received a temporary colostomy about the types of foods the infant will be able to eat, which diet would the nurse recommend?

- ☐ 1. high-fiber diet
- ☐ 2. low-fat diet
- ☐ 3. high-residue diet
- ☐ 4. regular diet

46. A child with Hirschsprung's disease is to be discharged 1 or 2 days after a colostomy takedown surgery. After teaching the infant's parents about the overall effects of their infant's surgery, the nurse determines that the teaching has been effective when the parents make which statement?

- ☐ 1. "His abdomen will be large for a while."
- ☐ 2. "Toilet training may be difficult."
- ☐ 3. "We need to limit his intake of dairy products."
- ☐ 4. "We will give him vitamin supplements until he is an adolescent."

47. A parent of a 7-year-old child with Hirschsprung's disease and chronic constipation asks about increasing dietary fiber in the child's diet. Which food could the nurse recommend?

- ☐ 1. fruit juice
- ☐ 2. white bread
- ☐ 3. popcorn
- ☐ 4. pancakes

The Client with Diarrhea, Gastroenteritis, or Dehydration

48. A nurse is caring for a 10-month-old, weighing 8 kg, who was admitted for dehydration. The infant has vomited five times in the last 3 hours and has had no wet diapers in the last 8 hours. The nurse informs the healthcare provider (HCP). Which prescription should the nurse question?

- ☐ 1. Begin an intravenous line of D5W 0.45% normal saline at 40 mL/h.
- ☐ 2. NPO while vomiting persists.
- ☐ 3. Begin an intravenous line, and administer a fluid bolus of dextrose 25%.
- ☐ 4. Strict intake and output, weighing all diapers.

49. Which signs or symptoms suggest that an infant with diarrhea is dehydrated? Select all that apply.

- ☐ 1. tacky mucous membranes
- ☐ 2. sunken anterior fontanelle
- ☐ 3. salty saliva
- ☐ 4. restlessness
- ☐ 5. increased urine output

50. A child is admitted with a tentative diagnosis of shigella. The nurse performs which interventions? Select all that apply.

- ☐ 1. Assess the child for nausea and vomiting.
- ☐ 2. Collect a stool specimen for white blood cells (WBCs).
- ☐ 3. Place the child on airborne precautions.
- ☐ 4. Monitor the child for signs and symptoms of dehydration.
- ☐ 5. Initiate an intake and output record.

51. Which finding would **most** likely alert the nurse to the possibility that a preschooler is experiencing moderate dehydration?

- ☐ 1. deep, rapid respirations
- ☐ 2. diaphoresis
- ☐ 3. absence of tear formation
- ☐ 4. decreased urine specific gravity

52. Which finding would be **most** important in an 8-month-old infant admitted with severe diarrhea?

- ☐ 1. bowel sounds every 5 seconds
- ☐ 2. pale yellow urine
- ☐ 3. normal skin elasticity
- ☐ 4. depressed anterior fontanelle

53. Which assessment would be the **most** important for the nurse to include in the plan of care for an infant experiencing severe diarrhea?

- ☐ 1. monitoring the total 8-hour formula intake
- ☐ 2. weighing the infant each day
- ☐ 3. checking the anterior fontanelle every shift
- ☐ 4. monitoring abdominal skin turgor every shift

54. The healthcare provider (HCP) prescribes an intravenous infusion of 5% dextrose in 0.45 normal saline to be infused at 2 mL/kg/h in an infant who weighs 9 lb (4.1 kg). How many milliliters per hour of the solution should the nurse infuse? Round to one decimal place.

_____ mL/h.

55. A 3-year-old with dehydration has vomited three times in the last hour and continues to have frequent diarrhea stools. The child was admitted 2 days ago with gastroenteritis caused by rotavirus. The child weighs 22 kg, has a normal saline lock in his right hand, and has had 30 mL of urine output in the last 4 hours. Using the situation-background-assessment-recommendation (SBAR) technique for communication, the nurse calls the healthcare provider (HCP) with the recommendation for:

- ☐ 1. giving a dose of loperamide.
- ☐ 2. starting a fluid bolus of normal saline.
- ☐ 3. beginning an IV antibiotic.

- ☐ 4. establishing a Foley catheter.

56. Which intervention would be **most** appropriate for the nurse to teach the mother of a 6-month-old infant hospitalized with severe diarrhea to help her comfort her infant who is fussy?

- ☐ 1. offering a pacifier
- ☐ 2. placing a mobile above the crib
- ☐ 3. sitting at crib side talking to the infant
- ☐ 4. turning the television on to cartoons

57. What would the nurse identify as a **priority** nursing problem for an infant just admitted to the hospital with a diagnosis of gastroenteritis?

- ☐ 1. pain related to repeated episodes of vomiting
- ☐ 2. deficient fluid volume related to excessive losses from severe diarrhea
- ☐ 3. impaired parenting related to infant's loss of fluid
- ☐ 4. impaired urinary elimination related to increased fluid intake feeding pattern

58. The nurse teaches the father of an infant hospitalized with gastroenteritis about the next step of the treatment plan once the infant's condition has been controlled. The nurse determines that the father understands when he explains which intervention will occur with his infant?

- ☐ 1. The infant will receive clear liquids for a period of time.
- ☐ 2. Formula and juice will be offered.
- ☐ 3. Blood will be drawn daily to test for anemia.
- ☐ 4. The infant will be allowed to go to the playroom.

59. The mother of a toddler who has just been admitted with severe dehydration secondary to gastroenteritis says that she cannot stay with her child because she has to take care of her other children at home. Which of the responses by the nurse would be **most** appropriate?

- ☐ 1. "You really should not leave right now. Your child is very sick."
- ☐ 2. "I understand, but feel free to visit or call anytime to see how your child is doing."
- ☐ 3. "It really is not necessary to stay with your child. We will take very good care of him."

- ☐ 4. “Can you find someone to stay with your children? Your child needs you here.”

60. A 9-month-old is admitted because of dehydration. How should the nurse go about accurately monitoring fluid intake and output? Select all that apply.

- ☐ 1. weighing and recording all wet diapers
- ☐ 2. changing breast-feedings to bottle-feedings
- ☐ 3. obtaining an accurate daily weight
- ☐ 4. restricting fluids prior to weighing the child
- ☐ 5. obtaining an accurate stool count

61. The healthcare provider (HCP) prescribes intravenous fluid replacement therapy with potassium chloride to be added for a child with severe gastroenteritis. Before hanging the IV fluids with potassium chloride, which assessments would be **most** important?

- ☐ 1. ability to void
- ☐ 2. passage of stool today
- ☐ 3. baseline electrocardiogram
- ☐ 4. serum calcium level

62. Which finding would alert the nurse to suspect that a child with severe gastroenteritis who has been receiving intravenous therapy for the past several hours may be developing circulatory overload?

- ☐ 1. a drop in blood pressure
- ☐ 2. change to slow, deep respirations
- ☐ 3. auscultation of moist crackles
- ☐ 4. marked increase in urine output

63. The stool culture of a child with profuse diarrhea reveals *Salmonella* bacilli. After teaching the parent about the course of *Salmonella enteritidis*, which statement by the parent indicates effective teaching?

- ☐ 1. “Some people become carriers and stay infectious for a long time.”
- ☐ 2. “After the acute stage passes, the organism is usually not present in the stool.”
- ☐ 3. “Although the organism may be alive indefinitely, in time it will be of

no danger to anyone.”

- ☐ 4. “If my child continues to have the organism in the stool, an antitoxin can help destroy the organism.”

64. A child undergoes rehydration therapy after having diarrhea and dehydration. A nurse is teaching the child’s parents about dietary management after rehydration. The nurse understands that the teaching plan has been successful when the parents tell the nurse that they will follow which type of diet?

- ☐ 1. regular
- ☐ 2. clear liquid
- ☐ 3. full liquid
- ☐ 4. soft

65. When obtaining a history from the parents of a child diagnosed with diarrhea due to *Salmonella*, the nurse should ask the parents if the child has been exposed to which possible sources of infection?

- ☐ 1. nonrefrigerated custard
- ☐ 2. a pet canary
- ☐ 3. undercooked eggs
- ☐ 4. unwashed fruit

66. On a home visit following discharge from the hospital after treatment for severe gastroenteritis, the parent tells the nurse that a toddler answers “No!” and is difficult to manage. After discussing this further with the parent, the nurse explains that the child’s behavior is **most** likely the result of which factor?

- ☐ 1. beginning leadership skills
- ☐ 2. inherited personality trait
- ☐ 3. expression of individuality
- ☐ 4. usual lack of interest in everything

67. The parent of a toddler hospitalized for episodes of diarrhea reports that when the toddler cannot have things the way she wants, she throws her legs and arms around, screams, and cries. The mother says, “I do not know what to do!” After teaching the parent about ways to manage this behavior,

which statement indicates that the nurse's teaching was successful?

- ☐ 1. "Next time she screams and throws her legs, I will ignore the behavior."
- ☐ 2. "I will allow her to have what she wants once in a while."
- ☐ 3. "I will explain why she cannot have what she wants."
- ☐ 4. "When she behaves like this, I will tell her that she is being a bad girl."

68. The mother of a toilet-trained toddler who was admitted to the hospital for severe gastroenteritis and subsequent dehydration and is now at home asks the nurse why the child still wets the bed. What would be the nurse's **best** response?

- ☐ 1. "Hospitalization is a traumatic experience for children. Regression is common, and it takes time for them to return to their former behavior."
- ☐ 2. "The stress of hospitalization is hard for many children, but usually they have no problems when they return home."
- ☐ 3. "After returning home from being hospitalized, children still feel they should be the center of attention."
- ☐ 4. "Children do not feel comfortable in their home surroundings once they return home from being hospitalized."

The Client with Appendicitis

69. An adolescent is being seen in the clinic for abdominal pain with a fever. In what order should the nurse assess the abdomen? All options must be used.

1. auscultate

2. inspect

3. palpate

4. percuss

70. A child is admitted with a diagnosis of possible appendicitis. The child is in acute pain. Which nursing interventions would be appropriate prior to surgery to decrease pain? Select all that apply.

- ☐ 1. Offer an ice pack.
- ☐ 2. Apply a heating pad.
- ☐ 3. Encourage the child to assume a position of comfort.
- ☐ 4. Limit the child's activity.
- ☐ 5. Request a prescription for a cathartic.

71. A 10-year-old male is 24 hours postappendectomy. He is awake, alert, and oriented. He tells the nurse that he is experiencing pain. He has a prescription for morphine 1 to 2 mg PRN for pain. What is the **priority** nursing action in managing the child's pain?

- ☐ 1. Change the child's position in bed.
- ☐ 2. Obtain vital signs with a pain score.
- ☐ 3. Administer 1 mg morphine as prescribed.
- ☐ 4. Perform a head-to-toe assessment.

72. A typically developing preschool child is experiencing pain after an appendectomy. Which data collection tool is the **most** appropriate for the nurse to use to assess the pain?

- ☐ 1. visual analog scale
- ☐ 2. FLACC scale
- ☐ 3. numerical pain scale
- ☐ 4. FACES pain rating scale

73. A 7-year-old has had an appendectomy on November 12. He has had pain for the last 24 hours. There is a prescription to administer

acetaminophen with codeine every 3 to 4 hours as needed. The nurse is beginning the shift, and the child is requesting pain medication. The nurse reviews the chart below for pain history. Based on the information in the medical record, what should the nurse do **next**?

- ☐ 1. Administer the acetaminophen with codeine.
- ☐ 2. Distract the child by giving him breakfast.
- ☐ 3. Instruct the child to take deep breaths and blow his pain away.
- ☐ 4. Assess the child again in 1 hour.

Nurses Progress Notes

Date	Time	Progress Notes
11/12	1500	Tylenol with Codeine given PO. FACES pain scale changed from 5 to 2 within 15 minutes
11/12	1800	Tylenol with Codeine given PO. FACES pain scale changed from 5 to 2
11/12	2130	Tylenol with Codeine given PO. FACES pain scale changed from 5 to 2
11/13	0100	Tylenol with Codeine given PO. FACES pain scale changed from 4 to 1
11/13	0700	Client rates pain on FACES pain scale as 4

74. When obtaining the initial health history from a 10-year-old child with abdominal pain and suspected appendicitis, which question would be **most** helpful in eliciting data to help support the diagnosis?

- ☐ 1. "Where did the pain start?"
- ☐ 2. "What did you do for the pain?"
- ☐ 3. "How often do you have a bowel movement?"
- ☐ 4. "Is the pain continuous, or does it let up?"

75. When developing the plan of care for a school-age child with a

suspected diagnosis of appendicitis who has severe abdominal pain, which measure should the nurse expect to include in the child's plan of care?

- ☐ 1. application of a heating pad
- ☐ 2. insertion of a rectal tube
- ☐ 3. application of an ice bag
- ☐ 4. administration of an intravenous narcotic

76. Which assessment finding should alert the nurse to suspect appendicitis in a male adolescent with severe abdominal pain?

- ☐ 1. Abdomen appears slightly rounded.
- ☐ 2. Bowel sounds are heard twice in 2 minutes.
- ☐ 3. All four abdominal quadrants reveal tympany.
- ☐ 4. The client demonstrates a cremasteric reflex.

77. An adolescent client scheduled for an emergency appendectomy is to be transferred directly from the emergency department to the operating room. Which statement by the client should the nurse interpret as **most** significant?

- ☐ 1. "All of a sudden, it does not hurt at all."
- ☐ 2. "The pain is centered around my navel."
- ☐ 3. "I feel like I am going to throw up."
- ☐ 4. "It hurts when you press on my stomach."

78. A nurse admits a pediatric client weighing 11.6 kg at the time of surgery for appendicitis. The nurse reviews the unit's standing prescription for IV fluids rates (see exhibit). At what hourly rate would the nurse set the IV pump?

History

Physical

Prescriptions

Diagnostics

1. Start an IV of lactated Ringers.
2. Run infusion at: (100 mL for each of the first 10 kg) + (50 mL for each kg 11-20) + (20 mL for each additional kg beyond 20)/24 hours.

79. What should be the **priority** assessment for an adolescent on return to the nursing unit after an appendectomy?

- ☐ 1. the dressings on the surgical sites
- ☐ 2. intravenous fluid infusion site
- ☐ 3. nasogastric (NG) tube function
- ☐ 4. amount of pain

80. An adolescent who has had an appendectomy and developed peritonitis has nausea. Which intervention should the nurse do **first**?

- ☐ 1. Administer an antiemetic.
- ☐ 2. Irrigate the nasogastric (NG) tube.
- ☐ 3. Notify the surgeon.
- ☐ 4. Take the blood pressure.

81. When developing the postoperative plan of care for an adolescent who has undergone an appendectomy for a ruptured appendix, in which position should the nurse expect to place the client during the early postoperative period?

- ☐ 1. semi-Fowler's position
- ☐ 2. supine
- ☐ 3. lithotomy position
- ☐ 4. prone

82. What would the nurse expect as a normal response from an adolescent

who has just returned to her room after an open appendectomy?

- ☐ 1. “I will need plastic surgery for this scar.”
- ☐ 2. “I am worried about the size of my scar.”
- ☐ 3. “I do not want to have any pain.”
- ☐ 4. “What will my boyfriend say about the scar?”

83. Which client action would the nurse judge to be a healthy coping behavior for a male adolescent after an appendectomy?

- ☐ 1. insisting on wearing a T-shirt and gym shorts rather than pajamas
- ☐ 2. avoiding interactions with other adolescents on the nursing unit
- ☐ 3. refusing to fill out the menu, and allowing the nurse to do so
- ☐ 4. not taking telephone calls from friends so he can rest

84. The nurse prepares to teach an adolescent scheduled for an appendectomy about what to expect. The adolescent says, “I would rather look this up on the Internet.” The nurse should:

- ☐ 1. explain that completing a teaching checklist is required by the hospital.
- ☐ 2. help the client find information on the Internet.
- ☐ 3. provide the client with written information instead.
- ☐ 4. explain that information found on the Internet cannot be trusted.

Managing Care, Quality, and Safety of Children with Health Problems of the Gastrointestinal Tract

85. The healthcare team has noticed an increase in IV infiltrations on the pediatric floor. As part of a Plan, Do, Study, Act quality improvement plan the team should perform the actions in which order? All options must be used.

1. Analyze the data.

2. Decide to monitor IV gauges.

3. Perform chart audits.

4. Write a new IV insertion policy.

86. The healthcare team wishes to establish a policy regarding sleep positions for infants with gastroesophageal reflux. The **first** step should be to search for:

- ☐ 1. policies from other hospitals.
- ☐ 2. data from retrospective studies.
- ☐ 3. published national standards.
- ☐ 4. expert opinions.

87. The nurse is assisting another member of the healthcare team who is placing a peripherally inserted catheter in a 10-year-old with peritonitis from a ruptured appendix. The family is present in the treatment room to support the child. The nurse observes that the other team member has contaminated a sterile glove. The nurse should:

- ☐ 1. discuss the incident with the team member after the event.
- ☐ 2. report the incident to the nursing unit manager.
- ☐ 3. tell the team member the glove is contaminated.
- ☐ 4. ask the family to leave before confronting the team member.

88. The hospital is responding to a mass casualty disaster with adult and pediatric victims. After reallocating staff, the charge nurse on the pediatric floor should:

- ☐ 1. ask parents to leave to free up the parent sleep areas for incoming victims.
- ☐ 2. review the census for clients that are candidates for early discharge.
- ☐ 3. initiate paper charting backup.

- ☐ 4. change taking all vital signs to every 8 hours.

89. Eight hours ago, an infant with Hirschsprung's disease had surgery to create a colostomy. Which finding should alert the nurse to notify the healthcare provider (HCP) immediately?

- ☐ 1. a 3-cm increase in abdominal circumference
- ☐ 2. periods of occasional fussiness
- ☐ 3. absence of bowel sounds since surgery
- ☐ 4. appearance of a bright red stoma

Answers, Rationales, and Test-Taking Strategies

*The answers and rationales for each question follow below, along with keys () to the client need (CN) and cognitive level (CL) for each question. In addition, you will also see a glossary icon () highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 12–23 and pages 35–36 in Part 1 of this book.*

The Client with Cleft Lip and Palate

1. 3. Before corrective surgery for a cleft lip, the infant needs to consume formula or breast milk. Methods for feeding may need to be adjusted to fit the infant's needs because the infant with a cleft lip experiences a decreased ability to suck, which interferes with the infant's ability to compress the nipple. A special feeder may be used to feed the infant to ensure adequate caloric intake. Problems with infection and skin integrity in the mouth are uncommon because the areas of the defect are not open areas. Although crying may cause the infant to swallow more air because of the defect, crying poses no harm to the infant. There is no need to keep the infant's fingers out of the mouth preoperatively. The fingers will not harm the defect or cause an infection.

 CN: Reduction of risk potential; CL: Synthesize

2. 1. An infant with a cleft lip and palate typically swallows large amounts of air while being fed and therefore should be burped frequently. The soft palate defect allows air to be drawn into the pharynx with each swallow of formula. The stomach becomes distended with air, and regurgitation, possibly with aspiration, is likely if the infant is not burped frequently. Feeding frequently, even in small amounts, would not prevent swallowing of large amounts of air. A nipple placed in the back of the mouth is likely to cause the infant to gag and aspirate. Holding the infant in a supine position during feedings can also lead to regurgitation and aspiration of formula. The infant should be fed in an upright position.

 CN: Basic care and comfort; CL: Synthesize

3. 1. To keep the infant from disturbing the suture line by placing fingers or other objects in the mouth, either intentionally or accidentally, the restraints should be in place at all times. They should be removed for a short period, however, so that the underlying skin can be checked for any redness or breakdown. While the restraints are removed, the parents should be instructed to manually restrain the hands and arms.

 CN: Safety and infection control; CL: Evaluate

4. 2. Cleft lips are typically repaired during the first 6 months of life. This allows the child to form a better seal around the nipple of a bottle for feeding and strengthens muscles needed for speech. If the surgery is delayed until after 6 months, the child may have possible dental issues and problems with sucking. The repair is not done at birth because the infant must first gain weight to safely undergo surgery. The palate should be closed by 18 months to protect the formation of tooth buds and allow the infant to develop more normal speech patterns.

 CN: Management of care; CL: Analyze

5. 1. A cup is the preferred drinking or eating utensil after repair of a cleft palate. At the age when repair is done, the child is ordinarily able to drink from a cup. Use of a cup avoids having to place a utensil in the mouth, which would increase the potential for injury to the suture lines.

CN: Physiological adaptation; CL: Synthesize

The Client with Tracheoesophageal Fistula

6. 3. The drooling and excessive mucus production is highly suggestive of a tracheoesophageal fistula (TEF). The initial diagnosis is made when an orogastric catheter cannot be passed to the stomach. A lactation consult would be warranted only after determining feedings were safe to continue. While cyanosis can be a sign of sepsis and hypoglycemia, the cyanosis is most likely related to the excessive secretions and airway patency. A blood gas may be needed, but only after ruling out a TEF.

CN: Management of care; CL: Synthesize

7. 1. The parents of children born with defects often have feelings of guilt and ask what they might have done to cause the condition or how they might have avoided it. It is important to allow parents to express their feelings and to accept these feelings as normal reactions. Explaining that the parents are not at fault would not be appropriate until they have dealt with their feelings of guilt. Encouraging long-term planning generally is of little benefit to parents who are emotionally distraught. Additionally, the parents may interpret this as ignoring their feelings and confirming that they played a role in causing their child's anomaly. Urging the parents to visit their infant as often as possible would generally be of little help and could appear to the parents as though they are being "talked out" of their feelings.

CN: Psychosocial integrity; CL: Synthesize

8. 2. Although a TEF can include several different structural anomalies, the most common type involves a blind upper pouch and a fistula from the esophagus into the trachea. Other types include a blind pouch at the end of the esophagus with no connection to the trachea and a normal trachea and esophagus with an opening that connects them. A tightened muscle below the stomach and projectile vomiting of normal amounts of formula are characteristic of pyloric stenosis. Aganglionic megacolon is a lack of autonomic parasympathetic ganglion cells in a portion of the lower intestine. Gastroschisis occurs when the bowel herniates through a defect in the abdominal wall and no membrane covers the exposed bowel.

CN: Physiological adaptation; CL: Evaluate

9. 2. With a TEF, overflow of secretions into the larynx leads to laryngospasm. This obstruction to inspiration stimulates the strong contraction of accessory muscles of the thorax to assist the diaphragm in breathing. This produces substernal retractions. The laryngospasm that occurs with a TEF resolves quickly when secretions are removed from the oropharynx area. A barking cough is related to a relatively constant laryngeal narrowing, usually caused by edema seen with croup. It is not an indication of the need to suction. A decreased activity level and an increased respiratory rate in an infant with a TEF are usually the result of hypoxia, a relatively long-term and constant phenomenon in infants with a TEF.

CN: Physiological adaptation; CL: Analyze

10. 1. The best way to prevent air from entering the stomach when performing a bolus feeding on an infant through a gastrostomy tube is to open the clamp after all the formula has been placed in the syringe barrel. Doing so prevents air from mixing with the formula and thus being introduced into the stomach. Pouring all the formula into the barrel after opening the clamp, maintaining a continuous flow of formula down the side of the barrel after unclamping the tube, and allowing a small amount of formula to enter the stomach before adding more formula to the barrel permit air to enter the stomach.

CN: Reduction of risk potential; CL: Apply

11. 4. The nurse can help meet the psychological needs of an infant being fed through a gastrostomy tube by rocking the infant after a feeding. The infant soon learns to associate eating with a pleasurable experience and learns to trust the caregiver. Rocking the infant will not promote peristalsis or prevent regurgitation. Holding the baby will not relieve pressure on the surgical site. However, holding the child right after feeding promotes comfort and pleasure.

CN: Psychosocial integrity; CL: Apply

12. 4. When initiating oral feedings after surgical repair of a TEF, it is best to follow a plan of care in conjunction with observation of the infant's needs

and behavior known as cue-based feedings. When sticking to a strict feeding schedule that overlooks the infant's readiness, plans are likely to be unsatisfactory and are more likely to meet the nurse's needs rather than the infant's needs. After a surgical procedure, infants initially tolerate small amounts of fluids offered more frequently better than larger amounts offered less often. Smaller amounts cause less bloating as the infant becomes used to feeding again. Although infants accept feedings more readily from their mother or from someone who feeds the infant repeatedly, the priority is to meet the infant's nutritional needs based on the infant's behavior.

CN: Basic care and comfort; CL: Create

The Client with an Anorectal Anomaly

13. 2. The nurse should honor the parent's belief system and help arrange to have the infant baptized. This may be done through the hospital's chaplaincy department or by the family's clergy. The parents may indeed be worried that the infant may die during surgery. Having the infant baptized would help address the family's spiritual needs. At this time, there is an immediate need for chaplaincy, not social service. While surgery may be postponed briefly, the infant cannot begin feeding until an outlet for stool has been established. Therefore, it is not advisable to postpone the surgery for a prolonged period of time.

CN: Psychosocial integrity; CL: Analyze

14. 1,3,4. Anorectal malformations present with lack of stool or evidence of meconium in the urine through a fistula. Meconium is not found in the stool. Because stool does not pass, abdominal distention and vomiting occur.

CN: Physiological adaptation; CL: Analyze

15. 4. Children who undergo surgical correction for low anorectal anomalies as infants usually are continent. Fecal continence can be expected after successful correction of anal membrane atresia. Therefore, this child probably has a good chance of being potty trained and will not need to wear protective pads. Extra fluids and a high-fiber diet are not required to prevent constipation. Children with high anorectal anomalies may or may not achieve continence.

 CN: Physiological adaptation; CL: Evaluate

16. 3. After surgical repair for an imperforate anus, the infant should be positioned either supine with the legs suspended at a 90-degree angle or on either side with the hips elevated to prevent pressure on the perineum. A neonate who is placed on the abdomen pulls the legs up under the body, which puts tension on the perineum, as does positioning the neonate on the back with the legs extended straight out.

 CN: Basic care and comfort; CL: Synthesize

17. 3. The neonate responds to pain with total body movement and brief, loud crying that ceases with distraction. After the age of 6 months, an infant reacts to pain with intense physical resistance and tries to escape by rolling away. A toddler reacts to pain by withdrawing the affected part.

 CN: Basic care and comfort; CL: Apply

18. 2. Encouraging the parents to hold their neonate promotes parent-infant attachment. Parent-infant bonding is based on a relationship that begins when the parent first touches the infant. Both the parents and the infant have predictable steps that they go through in this process. Explaining that the parents can visit at any time promotes bonding only if they do visit with, talk to, and hold the newborn. Asking the parents to help monitor intake and output at this time may be too anxiety producing, thus interfering with bonding. Helping the parents plan for the infant's discharge involves them in the newborn's care and is important. However, it is not the first step in the development of bonding.

 CN: Psychosocial integrity; CL: Synthesize

The Client with Pyloric Stenosis

19. 3. The vomitus of an infant with hypertrophic pyloric stenosis contains gastric contents, mucus, and streaks of blood. The vomitus does not contain bile or stool because the pyloric constriction is proximal to the ampulla of Vater.

 CN: Physiological adaptation; CL: Analyze

20. 1. Unless the infant is in hypovolemic shock, obtaining a baseline weight is an important first action because the weight is used to calculate the child's fluid and electrolyte needs. The intravenous fluid rate and the amounts of electrolytes to be added to the fluid are based on the infant's weight. The weight also helps determine the infant's degree of dehydration. The intravenous infusion is initiated once the weight has been obtained. The child with pyloric stenosis typically experiences vomiting and is at risk for fluid volume deficit and metabolic acidosis. As a result, oral food and fluids are withheld, and the infant is allowed nothing by mouth. Fluid replacement is given intravenously. Orientation can wait until treatment is under way.

CN: Physiological adaptation; CL: Synthesize

21. 1. Pyloric stenosis involves hypertrophy of the pylorus muscle distal to the stomach and obstruction of the gastric outlet resulting in vomiting, metabolic acidosis, and dehydration. Telescoping of the bowel is called intussusception. Overfeeding, feeding too quickly, or underfeeding is not associated with pyloric stenosis.

CN: Physiological adaptation; CL: Evaluate

22. 3. Normal serum potassium levels are 3.5 to 4.5 mEq/L (3.5 to 4.5 mmol/L). Elevated potassium levels can cause life-threatening cardiac arrhythmias. The nurse must verify that the client has the ability to clear potassium through urination before administering the drug. Infants with pyloric stenosis frequently have low potassium levels due to vomiting. A level of 3.4 mEq/L (3.4 mmol/L) is not unexpected and should be corrected with the prescribed fluids. The lab value does not need to be redrawn as the findings are consistent with the infant's condition.

CN: Pharmacological and parenteral therapies; CL: Synthesize

23. 4. Restating or rephrasing a mother's response provides the opportunity for clarification and validation. It also helps to focus on what the mother is saying and address her concerns and feelings. Although surgery is the most effective treatment for pyloric stenosis, stating this ignores the mother's feelings and does not give her an opportunity to express them. Telling the mother not to worry also ignores the mother's feelings. Additionally, this type of statement gives the mother premature reassurance,

which may turn out to be false. Asking the mother if she thinks the problem indicates that she is not a good mother implies such an idea. It does not allow her to express her concerns and feelings and therefore is not a therapeutic response.

CN: Psychosocial integrity; CL: Synthesize

24. 1. Clear liquids containing glucose and electrolytes are usually prescribed 4 to 6 hours after surgery. If significant vomiting does not occur, formula or breast milk then can be gradually substituted for clear liquids until the infant is taking normal feedings.

CN: Physiological adaptation; CL: Evaluate

25. 4. Giving the infant a pacifier would help meet nonnutritive sucking needs and ensure oral gratification. Additionally, sucking aids in calming the infant. Holding the infant to decrease fussiness and restlessness is more effective in an older infant. Also, the reason for the infant's fussiness needs to be explored. Hanging a mobile over the crib frequently does not decrease fussiness. After surgery to correct pyloric stenosis, feeding the infant more formula would lead to vomiting, putting additional stress on the operative site.

CN: Reduction of risk potential; CL: Synthesize

26. 2. The parents' ability to verbalize the infant's care realistically indicates that they are working through their fears and concerns. This behavior demonstrates an understanding of the infant's condition and needs. Without further data, the fact that the parents have to get away could be interpreted as ineffective coping, possibly suggesting that they are unable to handle the situation. Continuing to ask about the child's general condition even after answers have been given does not suggest effective coping. The parents are demonstrating that they are unsure of themselves as parents or are hoping for positive information. Exhibiting fear that they will disturb the infant does not suggest effective coping. This behavior indicates that they are uncertain or lack knowledge about infants.

CN: Psychosocial integrity; CL: Analyze

27. 4. Following pyloromyotomy, the infant should be positioned with the

head elevated and slightly on the right side to promote gastric emptying; the parents have positioned their infant correctly. The infant should be positioned on the right side, not the left side. When the child is in a crib, the head can be elevated, and the infant can be propped on the right side. The infant can use a pacifier if needed.

CN: Basic care and comfort; CL: Evaluate

The Client with Intussusception

28. 2. The infant with intussusception experiences acute episodes of colic-like abdominal pain. Typically, the infant screams and draws the knees to the chest. Between these episodes of acute abdominal pain, the infant appears comfortable and normal. Feeding does not precipitate episodes of pain. Additionally, a 4-month-old infant typically would not be ingesting solid foods. Pain exhibited by crying that occurs when the infant is placed in a reclining position, as in the mother's arms, is not associated with intussusception. This type of cry may indicate that the infant wants attention, wants to be held, or needs to have a diaper change.

CN: Physiological adaptation; CL: Analyze

29. 1. For the infant with intussusception, stools characteristically have the appearance of currant jelly because of the intestinal inflammation and hemorrhage resulting from intestinal obstruction. These stools occur later in the course of the disease process. Questions that focus on urination, vomiting, and food intake do not elicit information about the effects of intussusception.

CN: Physiological adaptation; CL: Analyze

30. 1. The first action is to check the placement of the tube to ensure that it is in the correct position. To check tube position, the nurse should aspirate the tube with a syringe. A return of gastric contents indicates that the end of the tube is in the stomach. Another method is to inject a small amount of air while auscultating with a stethoscope over the epigastric area. The tube is irrigated with normal saline to prevent electrolyte imbalances, not distilled water, and only after the position of the tube is confirmed. The suction level should not be increased because doing so could damage the mucosa. Rotating the tube could irritate or traumatize the nasal mucosa.

 CN: Reduction of risk potential; CL: Synthesize

31. 2. Development of a paralytic ileus postoperatively is a functional obstruction of the bowel. Bowel sounds initially may be hyperactive, but then they diminish and cease. Measurement of urine specific gravity provides information about fluid and electrolyte status. The first stool and the amount of gastric output provide information about the return of gastric function.

 CN: Physiological adaptation; CL: Analyze

32. 1. Infants who have had an interruption in their normal routine and experiences, such as hospitalization and surgery, typically manifest behavior changes when discharged. The infant's normal routine has been significantly altered, so it will take time to reestablish another routine. Calorie requirements at home will continue to be the same as those in the hospital. The infant does not need more calories at home. The surgical procedure corrected the problems, so the infant should not continue to have abdominal cramping.

 CN: Physiological adaptation; CL: Create

The Client with Inguinal Hernia

33. 1. Abdominal distention and a redness of the inguinal swelling are significant findings. Their presence in conjunction with area tenderness and inability to reduce the hernia indicate an incarcerated hernia. An incarcerated hernia can lead to strangulation, necrosis, and gangrene of the bowel. Other findings associated with strangulation include irritability, anorexia, and difficulty in defecation. A strangulated hernia necessitates immediate surgical intervention. The ability to reduce the hernia and normal stooling do not indicate it is incarcerated. Irritability is nonspecific and could be caused by various factors. A palpable, thickened spermatic cord on the affected side is diagnostic of inguinal hernia and would be an expected finding. A wet diaper indicates that urine is being excreted, a finding unrelated to inguinal hernia.

 CN: Physiological adaptation; CL: Analyze

34. 3. If nonoperative reduction is successful, delaying surgery for 2 to 3 days allows the edema and inflammation in the inguinal area to subside.

Thus, the area to be operated will appear more normal, helping to decrease the risk of complications. The preoperative preparation for a herniorrhaphy is minimal and is not the reason for delaying the surgery. Typically, the infant is fed until a few hours before surgery to prevent dehydration. Trusses do not prevent incarceration, and there is no reason to use a truss preoperatively.

CN: Physiological adaptation; CL: Apply

35. 2. The best way to prepare a 7-month-old infant psychologically for surgery is to have the primary caretaker stay with the child. Infants in the second 6 months of life commonly develop separation anxiety. Therefore, the priority in this case is to support the child by having the parent present. Teaching the mother what to expect may decrease her anxiety; this is important because infants sense anxiety and distress in parents, but the priority in this case is to have the parent present. Actual play and acting out life experiences are appropriate for preschool-age children. Allowing an infant to play with surgical equipment would be inappropriate and dangerous.

CN: Psychosocial integrity; CL: Synthesize

36. 1. Changing a diaper as soon as it becomes soiled helps prevent wound infection, the most common complication after inguinal hernia repair in an infant secondary to possible wound contamination with urine and stool. Because the surgical wound is unlikely to separate, an abdominal binder is unnecessary. The incision may or may not be covered with a dressing. If a dressing is not used, the **healthcare provider (HCP)**  may apply a topical spray to protect the wound. Restraining the infant's hands is unnecessary if the diaper is applied snugly. The infant would be unable to get the hands into the diaper close to the surgical site.

CN: Safety and infection control; CL: Create

37. 3. The incision must be kept as clean and dry as possible. Therefore, daily sponge baths are given for about 1 week postoperatively. Cleaning the infant's face and diaper area should occur at least daily and continuously, not limited to a 2-week period. Because this type of surgery results in a wound that heals through primary intention, the skin will heal and cover the wound in 2 to 3 days. Therefore, it is not necessary to use sterile gauze to cleanse the incision; clean technique is acceptable. Because the incision must be kept as

clean and dry, full tub baths are inappropriate.

CN: Reduction of risk potential; CL: Synthesize

The Client with Hirschsprung's Disease

38. 2. Infants with Hirschsprung's disease typically display failure to thrive, with poor weight gain due to malabsorption of nutrients. Therefore, the nurse would expect to see a child who weighs less than that which is expected for height and age. A distended, rather than a scaphoid-shaped, abdomen would be noted. Cyanosis of fingers and toes is associated with congenital heart disease. Hyperactive deep tendon reflexes are associated with upper motor neuron problems, such as cerebral palsy.

CN: Physiological adaptation; CL: Analyze

39. 3. By encouraging parents to ask questions during information-sharing sessions, the nurse can clarify misconceptions and determine the parents' understanding of information. A better understanding of what is happening allows the parents to feel some control over the situation. Assessing the adequacy of the parents' coping skills is important but secondary to encouraging them to express their concerns. The questions they ask and their interactions with the nurse may provide clues to the adequacy of their coping skills. The nurse should never give false reassurance to parents. At this point, there is no way for the nurse to know whether the child will be fine. Written materials are appropriate for augmenting the nurse's verbal communication. However, these are secondary to encouraging questions.

CN: Psychosocial integrity; CL: Synthesize

40. 3. The primary defect in Hirschsprung's disease is an absence of autonomic parasympathetic ganglion cells in the distal portion of the colon. Thus, the nerves at the end of the large colon are missing. Absence of a rectal opening refers to an imperforate anus. A tube between the trachea and esophagus refers to a tracheoesophageal fistula. Presence of a tight muscle below the stomach refers to pyloric stenosis.

CN: Physiological adaptation; CL: Evaluate

41. 3. Before intestinal surgery, dietary intake is limited to clear liquids for

24 to 48 hours. A clear liquid diet meets the child's fluid needs and avoids the formation of fecal material in the intestine. Typically, repeated saline enemas, not tap water enemas, are given to empty the bowel. Soapsuds enemas are contraindicated for infants, as are tap water enemas. A nasogastric tube may be inserted for gastric decompression. Insertion of a gastrostomy tube is outside the scope of nursing practice. Because the perineal area is not involved in the surgery, it does not need to be prepared.

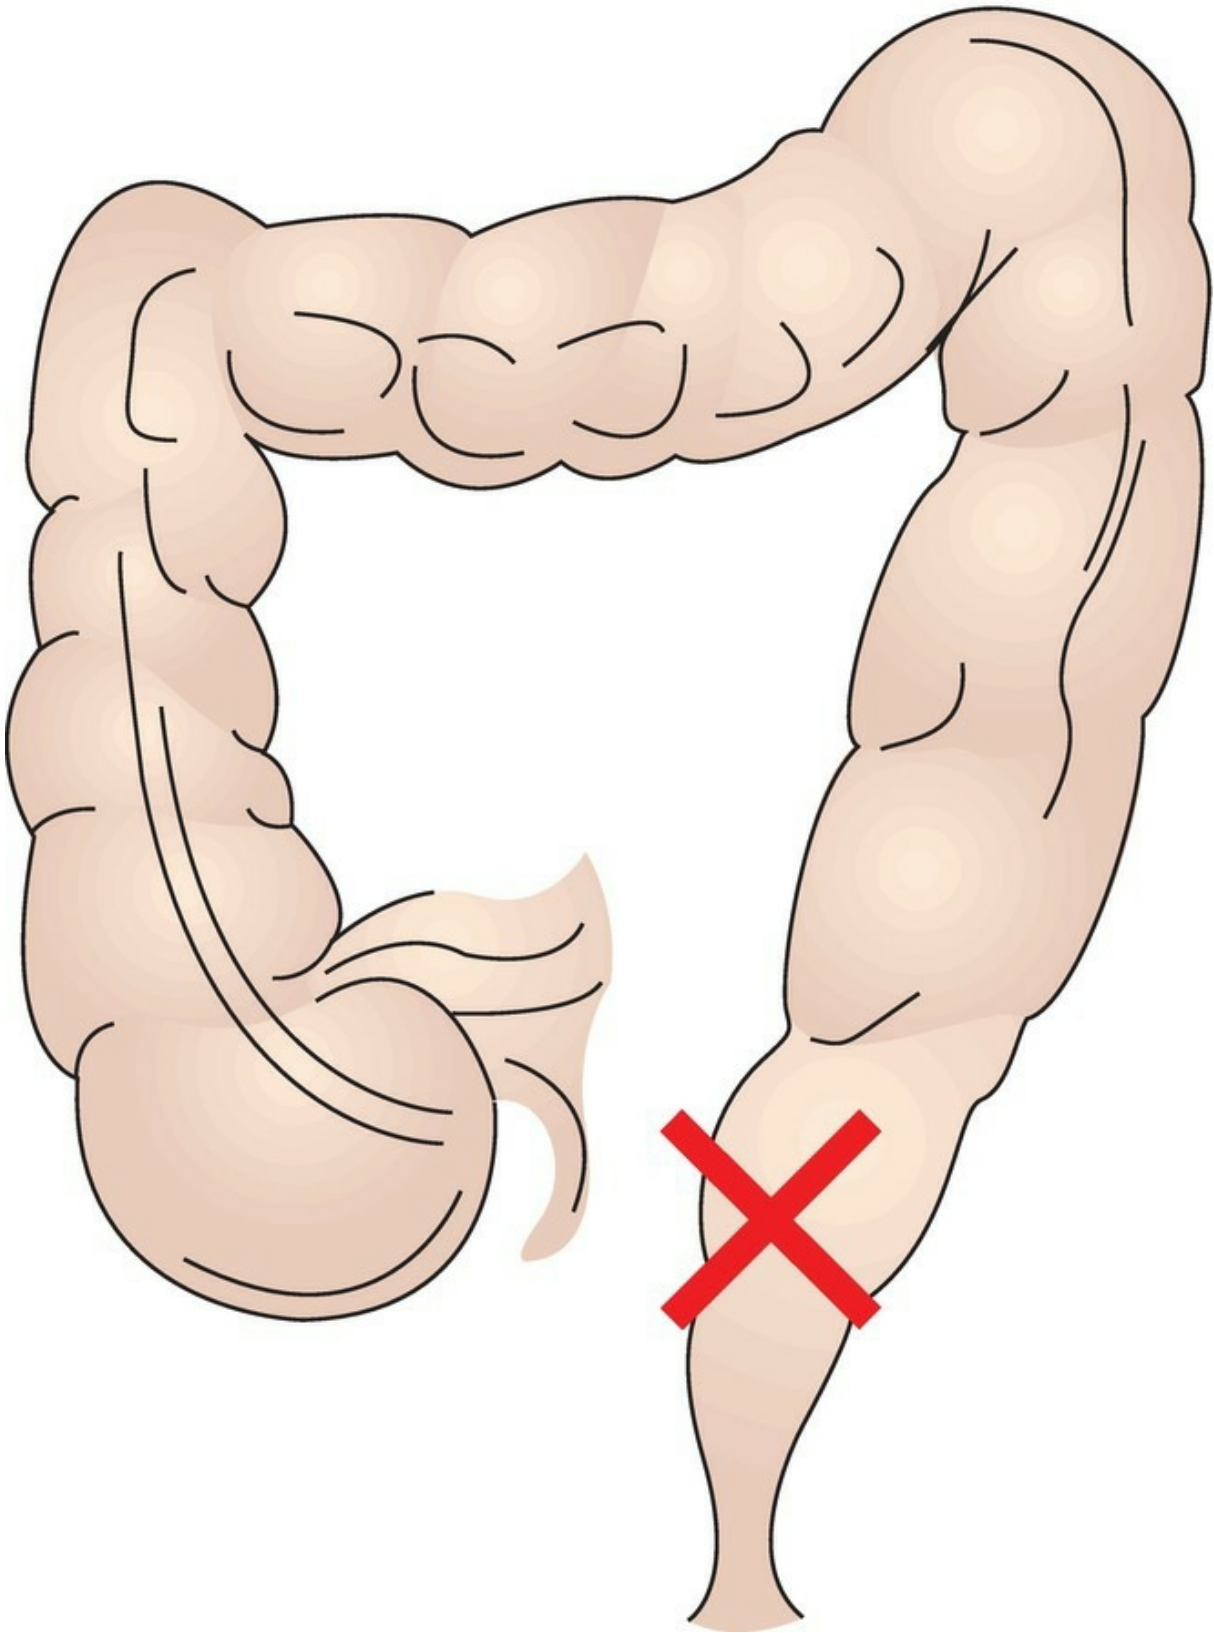

CN: Physiological adaptation; CL: Create

42. In most instances, the absence of ganglionic innervation occurs in the lower portion of the sigmoid colon just above the anus.

CN: Physiological adaptation; CL: Apply

43. 2. The goal of the surgery is to remove the aganglionic portion of the

intestine. The remaining intestines should have normal innervation. Colostomies are used to relieve the obstruction and allow the remaining intestines to return to normal size. A temporary loop or double-barreled colostomy has stomas for both the proximal and distal portion of the bowel. The final surgical repair is usually done when the infant is around 20 lb (9.1 kg). A new stoma is frequently swollen and bruised after surgery.

 CN: Physiological adaptation; CL: Evaluate

44. 2. Typically, the stoma should remain deep red in color as long as the infant has the colostomy. A dark red to purplish color may indicate impaired circulation to the stoma.

 CN: Physiological adaptation; CL: Create

45. 4. A regular diet would be recommended for the child with a colostomy; no special diet is needed. A high-fiber diet is not necessary. Fat is necessary for brain growth in the first year of life. A high-residue diet would result in bulkier stools and increased gas production, which will collect in the colostomy bag. Therefore, a high-residue diet is not indicated.

 CN: Basic care and comfort; CL: Apply

46. 2. Toilet training is commonly more difficult for children who have undergone surgery for Hirschsprung's disease than it is for other children. This is because of the trauma to the area and the associated psychological implications. Abdominal distention is an early sign of infection, and therefore the parents need to report it to the **healthcare provider (HCP)** . Typically, dietary restrictions are not required, but fiber is encouraged. Usually, the infant is placed on an age-appropriate diet. Vitamin supplementation is not necessary if the infant's dietary intake is adequate.

 CN: Physiological adaptation; CL: Evaluate

47. 3. Popcorn is high in fiber. Foods high in fiber help the bowels move. Constipation may be managed initially with increased fiber and fluids. White bread, fruit juice, and pancakes are foods that are not high in fiber.

 CN: Health promotion and maintenance; CL: Analyze

The Client with Diarrhea, Gastroenteritis, or Dehydration

48. 3. The infant is in need of a fluid bolus. A fluid bolus should consist of an isotonic fluid such as normal saline or lactated Ringer's. Dextrose 25% is not an appropriate bolus for dehydrated children because it could cause a fluid shift that may result in cerebral edema and death; thus, the nurse should question the prescription. D545% normal saline is an appropriate IV fluid for infants. The rate is 1.5 times maintenance for this child and is appropriate for the first 24 hours if the child is dehydrated. Once hydration is adequate, the infant's IV rate should be reduced to a maintenance rate. Vomiting is persistent, so it is appropriate for the child to be NPO. Strict I and O is an appropriate prescription for all dehydrated children.

CN: Safety and infection control; CL: Analyze

49. 1,2,4. Diarrhea in infants is a serious condition as it can proceed rapidly to dehydration. Clinical signs of dehydration are irritability and restlessness, weakness, stupor, loss of body weight, poor skin turgor, and sunken fontanelles. The urine output is decreased in dehydrated infants. The saliva decreases with dehydration and is not salty.

CN: Physiologic adaptation; CL: Analyze

50. 1,2,4,5. Shigella is caused by the *Shigella* organism. Clinical manifestations of shigella include fever, nausea and vomiting, some cramping, headache, seizures, rectal prolapse, and loose, watery stools containing pus, mucus, and blood. The nurse should assess the child for these symptoms on an ongoing basis. Shigella is spread via direct contact with the organism, which is found in the stool. A stool specimen will show increased numbers of WBCs, blood, and mucus. Vomiting and loose stools can result in severe dehydration and electrolyte imbalance. Thus, the nurse should record intake, output, and daily weights. There is no need for strict isolation; masks are not needed as shigella is not transmitted by airborne methods.

CN: Physiological adaptation; CL: Synthesize

51. 3. The absence of tears is typically found when moderate dehydration is observed as the body attempts to conserve fluids. Other typical findings associated with moderate dehydration include a dry mouth, sunken eyes, poor skin turgor, and an increased pulse rate. Deep, rapid respirations are associated with severe dehydration. Decreased perspiration, not diaphoresis,

would be seen with moderate dehydration. The specific gravity of urine increases with decreased output in the presence of dehydration.

 CN: Reduction of risk potential; CL: Analyze

52. 4. An infant with severe diarrhea will experience some degree of dehydration. In an 8-month-old child, the anterior fontanelle has not closed. Therefore, a depressed anterior fontanelle would be an important finding. Additionally, the infant would exhibit dry mucous membranes, lethargy, hyperactive bowel sounds, dark urine, and sunken eyeballs. Skin turgor would be decreased or delayed (e.g., slow to return when pinched). Bowel sounds every 5 seconds would not be considered abnormal for an infant.

 CN: Reduction of risk potential; CL: Analyze

53. 2. Because an infant experiencing severe diarrhea is at high risk for a fluid volume deficiency, the nurse needs to evaluate the infant's fluid balance status by weighing the infant at least every day. Body weight is the best indicator of hydration status because a higher proportion of an infant's body weight is water, compared with an adult. Initially, the infant with severe diarrhea is not allowed liquids but is given fluids intravenously. Therefore, monitoring the oral intake of formula is inappropriate. Although checking the anterior fontanelle for depression or bulging provides information about hydration status, this method is not considered the best indicator of the infant's fluid balance. Monitoring skin turgor can provide information about fluid volume status. The abdomen is commonly used to assess skin turgor in an infant because it is a large surface area and can be accessed quickly. However, weight is the best indicator of fluid balance.

 CN: Physiological adaptation; CL: Synthesize

54. 8.2 mL/h

$$4.1 \text{ kg} \times 2 \text{ mL/kg} = 8.2 \text{ mL/h}$$

 CN: Pharmacological and parenteral therapies; CL: Apply

55. 2. The child is dehydrated, is not able to retain oral fluids, and continues to have diarrhea. A normal saline bolus should be given followed by maintenance of IV fluids. Antidiarrheal medications are not recommended

for children and will prolong the illness. The child has gastroenteritis caused by a viral illness. IV antibiotics are not indicated for viral illnesses. Strict I&O is important in all children with gastroenteritis.

CN: Reduction of risk potential; CL: Apply

56. 1. Typically, an infant hospitalized with severe diarrhea receives fluid replacement intravenously rather than orally. Oral fluids and food are usually withheld. Although activities such as placing a mobile over the crib, speaking to the infant, or turning on the television may provide distraction for or help in calming the infant, a fussy infant receiving nothing by mouth is usually best comforted by providing a pacifier to satisfy sucking needs.

CN: Health promotion and maintenance; CL: Synthesize

57. 2. Given this infant's history of gastroenteritis, the priority problem would be fluid volume deficit. With gastroenteritis, vomiting and diarrhea occur, leading to the loss of fluids. This loss of fluids is problematic in infants because a higher proportion of their body weight is water. Pain is not a priority problem, although the nurse should continue to assess the infant for pain. There are no data to indicate impaired parenting. Impaired urinary elimination is related to the infant's fluid volume deficit resulting from vomiting and diarrhea associated with gastroenteritis. If the infant's fluid volume deficit is not corrected, then this nursing diagnosis may become the priority.

CN: Physiological adaptation; CL: Analyze

58. 1. The usual way to treat an infant hospitalized with gastroenteritis is to keep the infant nothing-by-mouth status to rest the gastrointestinal tract. The resulting fluid volume deficit is treated with intravenous fluids. When the infant's condition is controlled (e.g., when vomiting subsides), clear liquids are then started slowly. Formula and juice will be started once the infant's vomiting has subsided and the infant has demonstrated the ability to tolerate clear liquids for a period of time. In this situation, there is no need to test the infant's blood every day for anemia. Most likely, the infant's serum electrolyte levels would be monitored closely. Typically, an infant is placed in a private room because gastroenteritis is most commonly caused by a virus that is easily transmitted to others.

CN: Physiological adaptation; CL: Evaluate

59. 2. The nurse's best course of action would be to support the mother. This is best done by conveying understanding and encouraging the mother to visit or call. Telling the mother that she should not leave and that the child is very sick is critical and insensitive. Additionally, it implies guilt should the mother leave. Commenting that the child does not need anyone is not appropriate or true. Toddlers, in particular, need family members present because of the stresses associated with hospitalization. They experience separation anxiety, a normal aspect of development, and need constancy in their environment. Asking the mother to find someone else to stay with her children is inappropriate. The children at home also need the support of the mother and/or other family members to minimize the disruptions in family life resulting from the toddler's hospitalization and to maintain consistency.

CN: Psychosocial integrity; CL: Synthesize

60. 1,3,5. Accurate intake and output recording includes noting all intake, including IV fluids; noting output, such as emesis and stool; weighing diapers; measuring weight daily; measuring urine specific gravity; monitoring serum electrolytes; and monitoring for signs of dehydration. Children who are dehydrated must receive sufficient fluid intake, but having a breast-feeding child switch to bottle-feeding will not promote intake. Restricting fluids just prior to weighing the child will not alter the accuracy of the weight, and the nurse should continue to encourage fluids for this dehydrated child.

CN: Management of care; CL: Analyze

61. 1. Potassium chloride is readily excreted in the urine. Before hanging IV fluids with potassium chloride, the nurse should ascertain whether the child can void; if not, potassium chloride may build up in the serum and cause hyperkalemia. An electrocardiogram could be done during intravenous potassium replacement therapy to evaluate for these changes. Having a stool daily is important, but because potassium is primarily excreted in the urine, the child's ability to void must be verified. Serum calcium levels do not indicate the child's ability to tolerate potassium replacement.

CN: Pharmacological and parenteral therapies; CL: Analyze

62. 3. An early sign of circulatory overload is moist rales or crackles heard when auscultating over the chest wall. Elevated blood pressure, engorged neck veins, a wide variation between fluid intake and output (with a higher intake than output), shortness of breath, increased respiratory rate, dyspnea, and cyanosis occur later.

 CN: Reduction of risk potential; CL: Analyze

63. 1. After having *S. enteritidis*, some clients become chronic carriers of the causative organism and remain infectious for a long time as the organism continues to be shed from the body. During this time, the child is still considered infectious. No antitoxin is available to treat or prevent *Salmonella* infections.

 CN: Physiological adaptation; CL: Evaluate

64. 1. Dietary management following rehydration for diarrhea and mild dehydration would include offering the child a regular diet. Following rehydration, there is no need for the child to be on a special diet, such as a clear liquid, full liquid, or soft diet.

 CN: Basic care and comfort; CL: Evaluate

65. 3. Diarrhea related to *Salmonella* bacilli is commonly spread by raw or undercooked fowl and eggs, pet turtles, and kittens. Food poisoning caused by *Staphylococcus* species is commonly spread by inadequately cooked or refrigerated custards, cream fillings, or mayonnaise. Psittacosis, a respiratory illness, may be spread by canaries. Contaminated, unwashed fruit is associated with typhoid fever (caused by *Salmonella typhi*), a disorder rarely seen in the United States.

 CN: Physiological adaptation; CL: Analyze

66. 3. The “no” behavior demonstrated by a toddler is typical of this age group as the child attempts to be self-assertive as an individual. The negativism does not demonstrate an inherited personality trait or disinterest. Rather, it reflects the developmental task of establishing autonomy. The toddler is attempting to exert control over the environment. It is too early to assess leadership qualities in a toddler.

 CN: Health promotion and maintenance; CL: Analyze

67. 1. The child is demonstrating behavior associated with temper tantrums, which are relatively frequent normal occurrences during toddlerhood as the child attempts to develop a sense of autonomy. The development of autonomy requires opportunities for the child to make decisions and express individuality. Ignoring the outbursts is probably the best strategy. Doing so avoids rewarding the behavior and helps the child to learn limits, promoting the development of self-control. However, the mother should intervene in a temper tantrum if the child is likely to injure herself. Allowing the child to have what she wants occasionally would typically add to the problems associated with temper tantrums because doing so rewards the behavior and prevents the child from developing self-control. Toddlers do not possess the capacity to understand explanations about behavior. Expressing disappointment in the child's behavior or telling her that she is being a bad girl reinforces feelings of guilt and shame, thus interfering with the child's ability to develop a sense of autonomy.

CN: Health promotion and maintenance; CL: Evaluate

68. 1. Hospitalization is a traumatic time for a child, and it takes some time to readjust to the home environment. The child may regress at home for a period until she feels comfortable. Children normally do not dislike their home environment; in fact, they usually are eager to get home to familiar surroundings where they feel safe.

CN: Health promotion and maintenance; CL: Synthesize

The Client with Appendicitis

69. 2,1,4,3. The nurse should first inspect the abdomen for abnormalities. Auscultation should be done before percussion and palpation as vigorous touching may disturb the intestines. Percussion is next. Palpation is the last step as it is most likely to cause pain.

CN: Basic care and comfort; CL: Apply

70. 1,3,4. Cold is a vasoconstrictor and supplies some degree of anesthesia. The child is usually more comfortable on his side with his legs flexed to take the strain off the inflamed appendix. Limiting the child's activity puts less stress on the inflamed appendix and lessens the discomfort.

Heat increases circulation to an area, causing more engorgement and pain and, possibly, rupture of the appendix. Heat is contraindicated in any situation where rupture or perforation is a possibility. A cathartic is contraindicated when appendicitis is suspected. Increasing peristalsis can cause the appendix to rupture.

CN: Physiological adaptation; CL: Synthesize

71. 2. The child is in pain and needs intervention, but before the nurse can determine how to proceed, it is essential to know the client's pain score to determine the appropriate morphine dose. In addition, the nurse cannot evaluate the effectiveness of the pain medication if there is no pain score prior to administering the medication. Changing the child's position and administering pain medication may be helpful to relieve the child's pain, but the nurse must first know the severity of the pain before determining the appropriate intervention. The nurse must perform a head-to-toe assessment, but it is not the priority in managing the child's pain.

CN: Basic care and comfort; CL: Analyze

72. 4. The nurse should use the FACES pain rating scale for children aged three or older. The visual analog and numerical scales are used preferred with adults or older children who count well. The faces, legs, activity, cry, consolability (FLACC) scale is a behavioral scale that is appropriate for very small children or nonverbal children.

CN: Basic care and comfort; CL: Analyze

73. 1. The nurse should administer the acetaminophen with codeine as the client indicates he is having pain. Although the child reports less severe pain, he is still experiencing pain. The nurse will also want the child to have less pain because he will need to be more active during the day. Assessing the child later will likely cause the pain to have increased and be more difficult to manage. While distraction is appropriate for short-term pain, such as from a needlestick or pain that the child might be able to manage himself, postoperative pain should be relieved with medication.

CN: Basic care and comfort; CL: Synthesize

74. 1. The most helpful question would be to determine the location of the

pain when it started. The pain associated with appendicitis usually begins in the periumbilical area and then progresses to the right lower quadrant. After the nurse has determined the location of the pain, asking about what was done for the pain would be appropriate. Asking about the child's usual bowel movement pattern is a general question unrelated to child's condition. Children with appendicitis may have diarrhea or constipation. Additionally, knowledge about the child's usual pattern would not be a priority because the child with appendicitis typically is not hospitalized long enough to reestablish the normal pattern. Although the characteristics of the pain are important, asking if the pain is continuous or intermittent is vague and general because the pain could be associated with numerous conditions. With appendicitis, the client's pain may begin as intermittent, but it eventually becomes continuous.

CN: Physiological adaptation; CL: Analyze

75. 3. Application of an ice bag may help to relieve pain by decreasing circulation to the area. A heating pad is contraindicated because heat may increase circulation to the appendix, possibly leading to rupture. Rectal tubes are contraindicated because they stimulate bowel motility and can exacerbate abdominal pain. Also, they would be ineffective because accumulation of gas in the lower bowel is not likely to be the cause of the child's discomfort. Because narcotics can mask the child's symptoms, such as pain and discomfort, and they also decrease bowel motility, they are not given until after a definitive diagnosis has been made.

CN: Physiological adaptation; CL: Create

76. 2. Manifestations of appendicitis include decreased or absent bowel sounds. Normally, bowel sounds are heard every 10 to 30 seconds. Therefore, bowel sounds heard twice in 2 minutes suggests appendicitis. Normally, the contour of the male adolescent abdomen is flat to slightly rounded, and tympany is typically heard when auscultating over most of the abdomen. A cremasteric reflex is normal for male adolescents.

CN: Physiological adaptation; CL: Analyze

77. 1. Sudden relief of pain in a client with appendicitis may indicate that the appendix has ruptured. Rupture relieves the pressure within the appendix but spreads the infection to the peritoneal cavity. Periumbilical pain (pain

centered around the navel), vomiting, and abdominal tenderness on palpation are common findings associated with appendicitis.

 CN: Physiological adaptation; CL: Analyze

78. 45 mL/h. The nurse must first calculate the daily fluid requirements for a client weighing 11.6 kg. The daily maintenance fluid volume is divided by 24 hours.

$$100 \text{ mL} \times 10 \text{ kg} = 1000 \text{ mL}$$

$$50 \text{ mL} \times 1.6 \text{ kg} = 80 \text{ mL}$$

$$1000 + 80 = 1080 \text{ mL}$$

$$1080 \text{ mL} / 24 \text{ hours} = 45 \text{ mL/h}$$

 CN: Pharmacological and parenteral therapies; CL: Apply

79. 1. The priority assessment after an appendectomy would be the dressing over the surgical site to determine whether there is any drainage or bleeding. If the procedure was done laparoscopically, there may be more than one incision. Any surgical dressings should be clean, dry, and intact. Once the dressing has been assessed, the nurse would assess the intravenous infusion site, assess the NG tube to be sure it is functioning, and finally, determine the degree of pain the client is experiencing.

 CN: Physiological adaptation; CL: Analyze

80. 2. After an appendectomy, the client who develops peritonitis typically has an NG tube in place. When a client has nausea, the nurse would first check to ensure that the NG tube is functioning correctly because the client's nausea may be related to a blockage of the NG tube. If the tube is clogged, it can be irrigated with normal saline. An antiemetic may be given, but only after the nurse has determined that the NG tube is functioning properly. Postoperative prescriptions usually include an antiemetic. Typically, the nurse would notify the surgeon if the client did not obtain relief from

irrigation of the NG tube or administration of a prescribed antiemetic. Although taking the client's blood pressure is an important postoperative nursing activity, it is unrelated to relieving the client's nausea.

CN: Physiological adaptation; CL: Synthesize

81. 1. After an appendectomy for a ruptured appendix, assuming the semi-Fowler's or a right side-lying position helps localize the infection. These positions promote drainage from the peritoneal cavity and decrease the incidence of subdiaphragmatic abscess.

CN: Physiological adaptation; CL: Synthesize

82. 2. Adolescents are concerned about the immediate state and functioning of their bodies. The adolescent needs to know whether any changes (e.g., illness, trauma, surgery) will alter her lifestyle or interfere with her quest for physical perfection. Having a scar may be devastating to the adolescent. The need for plastic surgery cannot be determined at this point. The adolescent has just returned from surgery and has yet to see the scar. Healing has yet to occur. Typically, scars become smaller and fade over time. The desire for no pain is unrealistic. Although adolescents are worried about pain and how they will respond, they typically are discharged within 24 hours after an appendectomy with pain well controlled by oral analgesics. The immediate concern of adolescents is the state and functioning of their bodies. After concerns about themselves, then adolescents are concerned about their peer group and their responses. Although the boyfriend's response will matter, this concern would be more common later in the course of the adolescent's recovery.

CN: Health promotion and maintenance; CL: Analyze

83. 1. Adolescents struggle for independence and identity, needing to feel in control of situations and to conform to peers. Control and conformity are often manifested in appearance, including clothing, and this carries over into the hospital experience. The adolescent feels best when he is able to look and act as he normally does, for example, wearing a T-shirt and gym shorts. Adolescents normally want to interact with peers and commonly seek every opportunity to do so. Avoiding other adolescents on the nursing unit or not taking phone calls from friends might suggest ineffective coping behavior.

Refusing to fill out the menu and allowing the nurse to do so demonstrate dependent behavior, not a healthy coping mechanism.

CN: Psychosocial integrity; CL: Analyze

84. 2. Part of providing client-centered care is to honor the client's preferred method of learning. The nurse should help the adolescent find accurate information about the procedure. By assisting with the information search, the nurse can verify learning. Teaching straight from a checklist does not encourage customization. If the client has requested to use the Internet, it is unlikely that written information will be read. While it is true that some information on the Internet is not accurate, the nurse can take this opportunity to help the client learn how to determine if a source is reliable.

CN: Psychosocial integrity; CL: Synthesize

Managing Care, Quality, and Safety of Children with Health Problems of the Gastrointestinal Tract

85. 2,3,1,4. Deciding what to study and how to do it is part of the planning process. Collecting data through chart audits is part of the “do” phase. Once the chart audits are complete, the data may be “studied” or analyzed. The final step of the process, or the “act” phase, is to determine what should be done, which may include writing a new policy.

CN: Reduction of risk potential; CL: Synthesize

86. 3. Published national standards are based on the best evidence and when available should serve as the foundation for nursing unit policies. Policies from other hospitals may or may not be evidence based. Retrospective studies and expert opinions should only be used to form policy when data from experimental studies or national standards are not available.

CN: Reduction of risk potential; CL: Synthesize

87. 3. It is the responsibility of all healthcare members to protect the client. The team member may honestly not have realized that the glove was contaminated. Therefore, the nurse needs to alert the team member to the situation. Waiting until after the procedure to address the problem puts the child at unnecessary risk for infection. Asking the parents to leave could

invoke anxiety in both the child and the parents. Alerting the team member does not need to be confrontational. If done with a calm approach, the result is most likely to be gratitude instead of embarrassment.

CN: Reduction of risk potential; CL: Synthesize

88. 2. The charge nurse can anticipate needing beds for incoming victims. Any client who can go home should go home. Parents are a child's primary care givers and should not be asked to leave. If computers were not affected by the disaster, charting in the electronic health record is safer. Some routine procedures are altered during a disaster, but clients who are unstable will still need frequent assessments; reducing vital sign frequency must be considered on a case-to-case basis.

CN: Management of care; CL: Synthesize

89. 1. Abdominal circumference is measured to monitor for abdominal distention. An increase of 3 cm in 8 hours would require notification of the HCP ; it would indicate a substantial degree of abdominal distention, possibly from fluid or gas accumulation. Normally, after surgery, an infant experiences occasional periods of fussiness. However, as long as the infant is able to be quiet by himself or with the aid of a pacifier, the HCP does not need to be contacted. Absence of bowel sounds would be expected after surgery because of the effects of anesthesia. It takes approximately 48 hours for gastric motility to resume. New stomas are typically bright red or pink.

CN: Reduction of risk potential; CL: Synthesize

The Child with Health Problems Involving Ingestion, Nutrition, or Diet

- The Client with Toxic Substance Ingestion
- The Client with Lead Poisoning
- The Client with Celiac Disease
- The Client with Phenylketonuria
- The Client with Colic
- The Client with Obesity
- The Client with Food Sensitivity
- The Client with Failure to Thrive
- Managing Care, Quality, and Safety of Children with Health Problems Involving Ingestion, Nutrition, or Diet
- Answers, Rationales, and Test-Taking Strategies

The Client with Toxic Substance Ingestion

1. A toddler is brought to the emergency department after ingesting an undetermined amount of drain cleaner. The nurse should expect to assist with which intervention **first**?

- ☐ **1.** administering an emetic
- ☐ **2.** securing the airway
- ☐ **3.** performing gastric lavage
- ☐ **4.** inserting an indwelling urinary (Foley) catheter

2. After the acute stage following an ingestion of drain cleaner by a child, the nurse should be alert for the development of which likely complication?

- ☐ **1.** tracheal stenosis

- ☐ 2. tracheal varices
- ☐ 3. esophageal strictures
- ☐ 4. esophageal diverticula

3. The parents of a 3-year-old suspect that the child has recently ingested a large amount of acetaminophen. The child does not appear in immediate distress. The nurse should anticipate doing which intervention in order of priority, from first to last? All options must be used.

1. draw acetaminophen serum levels

2. attempt to determine the exact time and amount of drug ingested

3. administer acetylcysteine IV

4. administer activated charcoal

4. When developing the plan of care for a toddler who has taken an acetaminophen overdose, which intervention should the nurse expect to include as part of the initial treatment?

- ☐ 1. frequent blood level determinations
- ☐ 2. gastric lavage
- ☐ 3. tracheostomy
- ☐ 4. electrocardiogram

5. While assessing a preschooler brought by her parents to the emergency

department after ingestion of kerosene, the nurse should be alert for which complication?

- ☐ 1. uremia
- ☐ 2. hepatitis
- ☐ 3. carditis
- ☐ 4. pneumonitis

The Client with Lead Poisoning

6. Which statement by the parent of an 18-month-old child **most** indicates to the nurse that the child needs laboratory testing for lead levels?

- ☐ 1. "My child does not always wash after playing in the dirt."
- ☐ 2. "My child drinks two cups of milk every day."
- ☐ 3. "My child has more temper tantrums than other kids."
- ☐ 4. "My child is smaller than other kids of the same age."

7. In an initial screening for lead poisoning, a 2-year-old child is found to have a lead level of 10 mcg/dL (0.48 $\mu\text{mol/L}$). The nurse should:

- ☐ 1. arrange a follow-up appointment in 6 months.
- ☐ 2. obtain a consultation for chelation therapy.
- ☐ 3. educate parents on ways to reduce lead in the environment.
- ☐ 4. assure the parents this is a normal lead level.

8. When teaching the mother of a toddler diagnosed with lead poisoning, what should the nurse include as the **most** serious complication if the condition goes untreated?

- ☐ 1. cirrhosis of the liver
- ☐ 2. stunted growth rate
- ☐ 3. neurologic deficits
- ☐ 4. heart failure

9. The nurse is teaching dietary interventions to the parents of a child with an elevated blood lead level (EBLL). Which nutrient is **least** important to include in the child's diet?

- ☐ 1. calcium

- ☐ 2. iron
- ☐ 3. vitamin A
- ☐ 4. vitamin C

The Client with Celiac Disease

10. Which parent statement would suggest to the nurse that a child may have celiac disease and should be referred to a health care provider (HCP)?

- ☐ 1. "His urine is so dark in color."
- ☐ 2. "His stools are large and smelly."
- ☐ 3. "His belly is so small."
- ☐ 4. "He is so short."

11. During assessment of a child with celiac disease, the nurse would **most** likely note which physical finding?

- ☐ 1. enlarged liver
- ☐ 2. protuberant abdomen
- ☐ 3. tender inguinal lymph nodes
- ☐ 4. periorbital edema

12. After teaching the mother of a child with celiac disease about dietary management, which statement by the mother indicates successful teaching?

- ☐ 1. "I will feed my child foods that contain wheat products."
- ☐ 2. "I will be sure to give my child lots of milk."
- ☐ 3. "I will plan to feed my child foods that contain rice."
- ☐ 4. "I will be sure my child gets oatmeal every day."

13. The nurse is teaching the mother of a preschool-age child with celiac disease about a gluten-free diet. The nurse determines that the mother understands the diet if she tells the nurse she will prepare:

- ☐ 1. eggs and orange juice.
- ☐ 2. wheat toast and grape jelly.
- ☐ 3. oatmeal and skim milk.
- ☐ 4. rye toast and peanut butter.

14. Which foods would be appropriate for a 12-month-old child with

celiac disease?

- ☐ 1. oatmeal
- ☐ 2. pancakes
- ☐ 3. rice cereal
- ☐ 4. waffles

15. The parent of a child with celiac disease asks, “How long must he stay on this diet?” Which response by the nurse is **best**?

- ☐ 1. “Until the jejunal biopsy is normal.”
- ☐ 2. “Until his stools appear normal.”
- ☐ 3. “For the next 6 months.”
- ☐ 4. “For the rest of his life.”

The Client with Phenylketonuria

16. When preparing to obtain a neonatal screening test for phenylketonuria (PKU), the neonate must have received which to ensure reliable results?

- ☐ 1. a feeding of an iron-rich formula
- ☐ 2. nothing by mouth for 4 hours before the test
- ☐ 3. initial formula or breast milk at least 24 hours before the test
- ☐ 4. a feeding of glucose water

17. The nurse is assessing children at risk for phenylketonuria (PKU). Which child is at greatest risk?

- ☐ 1. a blond, blue-eyed, fair-skinned child with eczema
- ☐ 2. an African American, dark-eyed child with asthma
- ☐ 3. a child with dark complexion who is overweight and has labile personalities
- ☐ 4. a red-headed child who experiences frequent contact dermatitis

18. When developing the plan of care for a child diagnosed with phenylketonuria (PKU), the nurse should establish which goal?

- ☐ 1. meeting the child’s nutritional needs for optimal growth
- ☐ 2. ensuring that the special diet is started at age 3 weeks
- ☐ 3. maintaining serum phenylalanine level higher than 12 mg/100 mL (720

μmol/L)

- ☐ 4. maintaining serum phenylalanine level lower than 2 mg/100 mL (120 μmol/L)

19. When taking a diet history from the mother of a 7-year-old child with phenylketonuria, a report of an intake of which foods should cause the nurse to gather additional information?

- ☐ 1. diet cola
- ☐ 2. carrots
- ☐ 3. orange juice
- ☐ 4. bananas

20. Which foods would the nurse teach the parents of a child with phenylketonuria (PKU) to avoid? Select all that apply.

- ☐ 1. hamburger
- ☐ 2. hot dog
- ☐ 3. ice cream
- ☐ 4. juice
- ☐ 5. cereal

21. When teaching the mother of a child diagnosed with phenylketonuria (PKU) about its transmission, the nurse should use knowledge of which factor as the basis for the discussion?

- ☐ 1. chromosome translocation
- ☐ 2. chromosome deletion
- ☐ 3. autosomal recessive gene
- ☐ 4. X-linked recessive gene

22. A newborn diagnosed with phenylketonuria (PKU) is placed on a phenylalanine-free formula. The mother asks the nurse how long her infant will be taking this. Which response would be **most** appropriate?

- ☐ 1. "Until the infant is taking solid foods well."
- ☐ 2. "Until the child has stopped growing."
- ☐ 3. "Until the phenylalanine level remains below normal for 6 months."
- ☐ 4. "Probably for a long time, but it is not definitely known."

23. Even though several teaching sessions have been documented in the client's health record, the mother asks the nurse again what caused her child's phenylketonuria (PKU). Which statement would **best** reflect the nurse's interpretation of why the mother keeps asking for information that she has already received?

- ☐ **1.** Because the child's condition is chronic, parents commonly want very detailed explanations about the causes of and treatments for their child's disease.
- ☐ **2.** Parents of a chronically ill child commonly require a long time to work through the grieving process for their child's disease.
- ☐ **3.** Parents commonly test health workers' knowledge about the causes of and treatments for their child's disease.
- ☐ **4.** Parents commonly deal with their guilt about possibly causing their child's disease by asking challenging questions.

The Client with Colic

24. When performing the nursing history, which information would be **most** important for the nurse to obtain from the mother of an infant with suspected colic?

- ☐ **1.** the type of formula the infant is taking
- ☐ **2.** the infant's crying pattern
- ☐ **3.** the infant's sleep position
- ☐ **4.** the position of the infant during burping

25. The parents of a child with colic are asked to describe the infant's bowel movements. Which description should the nurse expect?

- ☐ **1.** soft, yellow stools
- ☐ **2.** frequent watery stools
- ☐ **3.** ribbon-like stools
- ☐ **4.** foul-smelling stools

26. The mother tells the nurse that the diagnosis of colic upsets her because she knows her infant will continue to have colicky pain. Which response by the nurse would be **most** appropriate?

- ☐ 1. "I know that your baby's crying upsets you, but she needs your undivided attention for the next few months."
- ☐ 2. "It can be difficult to listen to your baby cry so loud and so long, so try to make sure that you get some free time."
- ☐ 3. "It must be distressing to see your baby in pain, but at least she does not have an intestinal obstruction."
- ☐ 4. "The next 3 months will be a difficult time for you, but your baby will outgrow the colic by this time."

27. The nurse judges that the mother has understood the teaching about care of an infant with colic when the nurse observes the mother doing which action?

- ☐ 1. holding the infant prone while feeding
- ☐ 2. holding the infant in her lap to burp
- ☐ 3. placing the infant prone after the feeding
- ☐ 4. burping the infant during and after the feeding

The Client with Obesity

28. An 8-year-old has a body mass index (BMI) for age at the 90th percentile but has no other risk factors. The nurse should:

- ☐ 1. refer the family to a dietician.
- ☐ 2. recommend the child be reweighed in 1 year.
- ☐ 3. refer the child to a health care provider (HCP) specializing in pediatric weight loss.
- ☐ 4. recommend the child participate in a commercial diet program.

29. A parent brings a 7-month-old infant to the well-baby clinic for a check-up. The parent feeds the infant formula whenever the infant is hungry but is concerned that the infant is overweight. The nurse should instruct the parent to:

- ☐ 1. give the infant 2% milk formula and add vitamins.
- ☐ 2. use skim milk because it is high in protein and lower in calories.
- ☐ 3. decrease the amount of formula feedings to 16 oz (480 mL) daily and supplement with juice and water.

- ☐ 4. bring a 3-day record of the infant's intake back for further evaluation.

30. The nurse is providing nutrition counseling for an obese adolescent. The **most** effective method for the nurse to obtain a nutrition history from this client is to:

- ☐ 1. ask her what she knows about good nutrition.
- ☐ 2. tell her to list what she plans to eat for the next 24 hours.
- ☐ 3. ask her what she ate yesterday if it was a typical day.
- ☐ 4. telephone her mother and ask her what she ate yesterday.

31. When counseling an obese adolescent, the nurse should advise the client that which complication is the **most** common?

- ☐ 1. lifelong obesity
- ☐ 2. gastrointestinal problems
- ☐ 3. orthopedic problems
- ☐ 4. psychosocial problems

32. When developing a teaching plan for the mother of an infant about introducing solid foods into the diet, which measure should the nurse expect to include in the plan to help prevent obesity?

- ☐ 1. decreasing the amount of formula or breast milk intake as solid food intake increases
- ☐ 2. introducing the infant to the taste of vegetables by mixing them with formula or breast milk
- ☐ 3. mixing cereal and fruit in a bottle when offering solid food for the first few times
- ☐ 4. using a large-bowled spoon for feeding solid foods during the first several months

33. A pregnant mother who has brought her toddler to the clinic for a checkup asks the nurse how she can keep her next baby from becoming obese. The mother plans to bottle-feed her next child. Which information should the nurse include in the teaching plan to help the mother avoid overnourishing her infant?

- ☐ 1. recognizing clues indicating that the baby is full
- ☐ 2. establishing a regular feeding schedule

- ☐ 3. supplementing feedings with sterile water
- ☐ 4. adding more water than directed when preparing formula

The Client with Food Sensitivity

34. During a school party, a child with a known food allergy has an itchy throat, is wheezing, and is not feeling “quite right.” The nurse should do what in order from first to last? All options must be used.

1. Administer the child’s epinephrine.

2. Assess vital signs.

3. Position to facilitate breathing.

4. Send someone to activate the Emergency Management Systems (EMS).

5. Notify the parents.

35. After teaching the parents of a child with lactose intolerance about the disorder, the nurse determines that the teaching was effective when the mother uses which statement to describes the condition?

- ☐ 1. “The lack of an enzyme to break down lactose.”
- ☐ 2. “An allergy to lactose found in milk.”
- ☐ 3. “Inability to digest proteins completely.”

- ☐ 4. "Inability to digest fats completely."

36. After teaching the mother of a 2-year-old child with lactose intolerance about which dairy products to include in the child's diet, which food is stated by the mother indicates effective teaching?

- ☐ 1. ice cream
☐ 2. creamed soups
☐ 3. pudding
☐ 4. cheese

37. The breast-feeding mother of a 1-month-old diagnosed with cow's milk sensitivity asks the nurse what she should do about feeding her infant. Which recommendation would be **most** appropriate?

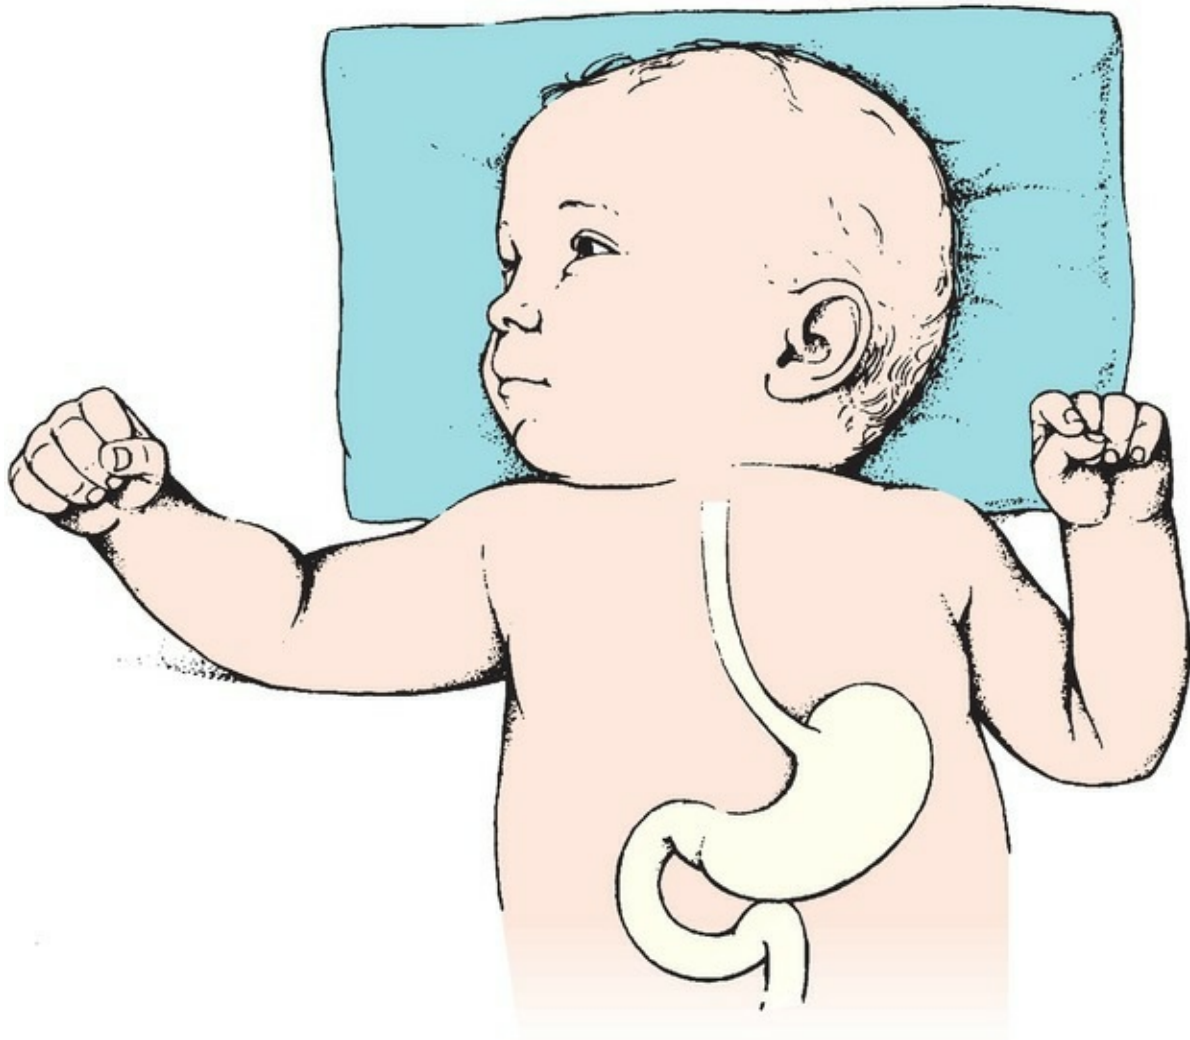

- ☐ 1. "Continue to breast-feed, but eliminate all milk products from your own diet."
☐ 2. "Discontinue breast-feeding, and start using a predigested formula."
☐ 3. "Limit breast-feeding to once per day and begin feeding an iron-fortified formula."
☐ 4. "Change to a soy-based formula exclusively and begin solid foods."

38. The nurse teaches the parents of a preschool child diagnosed with lactose intolerance how to incorporate dairy products into their child's diet. Which statement by the parent reflects the need for more teaching?

- ☐ 1. "My child should limit milk consumption to one small glass at a time."
☐ 2. "It is best to drink milk alone, not with meals."
☐ 3. "Eating hard cheese, cottage cheese, or yogurt may cause fewer symptoms than drinking milk."
☐ 4. "Using lactase enzymes or milk products containing lactase may help decrease gas."

The Client with Failure to Thrive

39. The nurse is inserting a nasogastric tube in an infant to administer feedings. In the figure below, indicate the location for the correct placement of the distal end of the tube.

40. The nurse formulates a plan of care to address negative feeding patterns for a 5-month-old infant diagnosed with failure to thrive. To meet the short-term outcomes of the infant's plan of care, the nurse should expect to implement which intervention?

- ☐ 1. Instruct the parents in proper feeding techniques.
- ☐ 2. Give the infant high-calorie formula.
- ☐ 3. Provide consistent staff to care for the infant.
- ☐ 4. Allow the infant to sit in a highchair during feedings.

41. The health care team determines that the family of an infant with failure to thrive who is to be discharged will need follow-up care. Which approach would be the **most** effective method of follow-up?

- ☐ 1. daily phone calls from the hospital nurse

- ☐ 2. enrollment in community parenting classes
- ☐ 3. twice-weekly clinic appointments
- ☐ 4. weekly visits by a community health nurse

Managing Care, Quality, and Safety of Children with Health Problems Involving Ingestion, Nutrition, or Diet

42. When providing intermittent nasogastric feedings to an infant with failure to thrive, which method is preferred to confirm tube placement before each feeding?

- ☐ 1. obtain a chest x-ray.
- ☐ 2. verify that the gastric pH is less than 5.5.
- ☐ 3. auscultate the stomach while instilling an air bolus.
- ☐ 4. compare the tube insertion length to a standardized chart.

43. When teaching parent workshops about measures to prevent lead poisoning in children, which preventive measure should the nurse include as the **most** effective?

- ☐ 1. condemning old housing developments
- ☐ 2. educating the public on common sources of lead
- ☐ 3. educating the public on the importance of good nutrition
- ☐ 4. keeping pregnant women out of old homes that are being remodeled

44. A child with a nut allergy presents with a severe reaction for the third time in 3 months. The parent says, “I am having trouble with the food labels.” The nurse should **first**:

- ☐ 1. assess the parent’s ability to read.
- ☐ 2. refer the client to the dietician.
- ☐ 3. notify the health care provider (HCP).
- ☐ 4. obtain a social service consult.

Answers, Rationales, and Test-Taking Strategies

The answers and the rationales for each question follow below, along with keys (🔑) to the client need (CN) and cognitive level (CL) for each

question. In addition, you will also see a glossary icon () highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 12–23 and pages 35–36 in Part 1 of this book.

The Client with Toxic Substance Ingestion

1. 2. Drain cleaner almost always contains lye, which can burn the mouth, pharynx, and esophagus on ingestion. The nurse would be prepared to assist with procedures to secure the airway, which may include intubation or performing a tracheostomy. An emetic is contraindicated because, as the substance burns on ingestion, so too would it burn when vomiting. Additionally, the mucosa becomes necrotic, and vomiting could lead to perforations. Gastric lavage is contraindicated because the mucosa is burned from the ingestion of the caustic lye, causing necrosis. Gastric lavage also could lead to perforation of the necrotic mucosa. Insertion of an indwelling urinary (Foley) catheter would be indicated after the measures to remove the caustic substance have been started.

CN: Reduction of risk potential; CL: Apply

2. 3. As the burn from the lye ingestion heals, scar tissue develops and can lead to esophageal strictures, a common complication of lye ingestion. Tracheal stenosis would occur if the child had vomited and aspirated. Tracheal varices do not commonly occur after the ingestion of lye or other substances. Although very rare, esophageal diverticula may occur. Diverticula are commonly found in the colon of adults.

CN: Physiological adaptation; CL: Analyze

3. 2,4,1,3. The nurse should **first** attempt to determine exactly when and how much acetaminophen the parents think the child has taken. Determining the time of ingestion helps establish the immediate care and when lab values should be drawn. Gastric decontamination with activated charcoal is used within 4 hours of ingestion to bind the drug and help prevent toxic serum

levels. Serum blood levels should be done after the gastric decontamination, but preferably not too soon after ingestion since levels drawn before 4 hours may not reflect maximum serum concentrations and will need to be repeated. The decision to administer acetylcysteine and prevent liver damage is based on serum levels.

CN: Pharmacological and parenteral therapies; CL: Synthesize

4. 2. Initial management of a child who has ingested a large amount of acetaminophen would include inducing vomiting or performing gastric lavage with or without activated charcoal to aid in the removal of the substance. Frequent blood level determinations may be obtained during the follow-up phase, but they are not done as part of the initial treatment. Tracheostomy is not typically part of the initial treatment for acetaminophen overdose. However, it may be necessary later if respiratory distress develops. Acetaminophen primarily affects the liver, not the heart. Therefore, an electrocardiogram would not be considered part of the initial treatment plan.

CN: Reduction of risk potential; CL: Apply

5. 4. Chemical pneumonitis is the most common complication of ingestion of hydrocarbons, such as in kerosene. The pneumonitis is caused by irritation from the hydrocarbons aspirated into the lungs. Uremia is the result of renal insufficiency, which causes nitrogenous waste products to build up in the blood rather than being excreted. Hepatitis is caused by a viral infection. Carditis in a preschooler may be the result of rheumatic fever.

CN: Physiological adaptation; CL: Analyze

The Client with Lead Poisoning

6. 1. Eating with dirty hands, especially after playing outside, can cause lead poisoning because lead is often present in soil surrounding homes. Also, children who eat lead-containing paint chips commonly develop lead poisoning. Milk is a major source of calcium, and diets high in calcium help prevent lead poisoning. Temper tantrums are characteristic of 18-month-old children as they try to assert themselves. Determining whether the child is smaller than other children the same age requires measuring height and weight and plotting them on growth charts. In addition, inadequate growth

could be a result of numerous causes, such as genetics, chronic illness, or chronic drug use (e.g., prednisone).

CN: Physiological adaptation; CL: Evaluate

7. 3. Treatment for children with minimally elevated lead levels should include family lead education, follow-up testing, and a social service consultation if needed. Waiting 6 months for a follow-up screening is too long because the effects of lead are irreversible. Oral chelation therapy is not begun until levels approach 45 mcg/dL (2.2 μ mol/L). There is no such thing as a “normal” lead level because there is no beneficial action in the body.

CN: Safety and infection control; CL: Synthesize

8. 3. The most serious and irreversible consequence of lead poisoning is neurologic changes leading to an intellectual disability. It can be expected if lead poisoning is long-standing and goes untreated. Lead poisoning also affects the hematologic and renal systems. Cirrhosis is the end stage of several chronic liver diseases, such as biliary atresia and hepatitis. Lead poisoning is not associated with stunted growth. Chronic illnesses, such as cystic fibrosis, cause slowing of the growth velocity. Heart failure is associated with congenital heart disease and rheumatic fever.

CN: Physiological adaptation; CL: Apply

9. 3. Vitamin A is not known to play a significant role in preventing EBL. Calcium intake inhibits lead absorption. Children with EBL levels often are anemic. While this relationship is not well understood, iron supplementation has been shown to improve developmental outcomes. Vitamin C improves iron absorption.

CN: Health promotion and maintenance; CL: Analyze

The Client with Celiac Disease

10. 2. Celiac disease is a disorder involving intolerance to the protein gluten, which is found in wheat, rye, oats, and barley. The stools of a child with celiac disease are characteristically malodorous, pale, large (bulky), and soft (loose). Excessive flatus is common, and bouts of diarrhea may occur. Dark urine is commonly associated with concentrated urine, such as when a

child has dehydration. The belly of a child with celiac disease, a malabsorption disorder, typically is protuberant. A small belly may be associated with a child who is thin. Short stature is not associated with this malabsorption disorder.

CN: Physiological adaptation; CL: Analyze

11. 2. The intestines of a child with celiac disease fill with accumulated undigested food and flatus, causing the characteristic protuberant abdomen. Celiac disease is not usually associated with any liver dysfunction, including poor liver functioning leading to liver enlargement. Tender inguinal lymph nodes are often associated with an infection. Periorbital edema, swelling around the eyes, is associated with nephritis.

CN: Physiological adaptation; CL: Analyze

12. 3. Damage to intestinal mucosa in celiac disease is caused by gliadin, a part of the gluten protein found in wheat, rye, barley, and oats. Foods containing these grains must be eliminated entirely from the diet of children with celiac disease. Foods containing rice and corn are a good substitute. Although an adequate intake of milk is important for any child, children with celiac disease do not need an increased milk intake.

□ CN: Physiological adaptation; CL: Evaluate

13. 1. Children with celiac disease cannot digest the protein in common grains such as wheat, rye, and oats. Eggs and orange juice would be appropriate foods.

 CN: Basic care and comfort; CL Evaluate

14. 3. The child with celiac disease should not eat foods containing wheat, oats, rye, or barley. Pancakes and waffles are made from flour that typically is derived from wheat and therefore should be avoided. Foods containing rice, such as rice cereal, or corn are appropriate. Pancakes and waffles are made from flour that typically is derived from wheat and therefore should be avoided.

 CN: Physiological adaptation; CL: Synthesize

15. 4. Most children with celiac disease have a lifelong sensitivity to gluten, which requires that they maintain some type of diet restriction for the rest of their lives.

 CN: Physiological adaptation; CL: Synthesize

The Client with Phenylketonuria

16. 3. PKU is an autosomal recessive disorder involving the absence of an enzyme needed to metabolize the essential amino acid phenylalanine to tyrosine. To ensure reliable results, the neonate must have ingested sufficient protein, such as breast milk or formula, for at least 24 hours. Testing the infant before that time, excessive vomiting, or poor intake can yield false-negative results. The infant does not need to fast 4 hours before the test. A loading dose of glucose water does not affect test values.

 CN: Reduction of risk potential; CL: Evaluate

17. 1. Infants with PKU are usually blond, blue-eyed, and fair and often have eczema. The other physical assessment findings are not typically found in children with PKU.

 CN: Reduction of risk potential CL: Analyze

18. 1. The goal of care is to prevent intellectual disabilities by adjusting the diet to meet the infant's nutritional needs for optimal growth. The diet needs to be started upon diagnosis, ideally within a few days of birth. Serum phenylalanine level should be maintained between 3 and 7 mg/100 mL (180 to 420 $\mu\text{mol/L}$). Significant brain damage usually occurs if the level exceeds 10 to 15 mg/100 mL (600 to 900 $\mu\text{mol/L}$). If the level drops below 2 mg/100 mL (120 $\mu\text{mol/L}$), the body begins to catabolize its protein stores, causing growth restriction.

CN: Physiological adaptation; CL: Create

19. 1. Foods with low phenylalanine levels include vegetables, fruits, and juices. Foods high in phenylalanine include meats and dairy products, which must be restricted or eliminated. Diet colas contain more phenylalanine than the fruits listed.

CN: Physiological adaptation; CL: Analyze

20. 1,2,3. Children with PKU lack an enzyme to metabolize phenylalanine and convert it to tyrosine. Treatment is dietary management to control the amount of phenylalanine ingested. Foods with low phenylalanine levels include fruits, most vegetables, and cereals. High-protein foods have high levels of phenylalanine and include meats and dairy products.

CN: Reduction of risk potential; CL: Create

21. 3. PKU is caused by an inborn error of metabolism. It is an autosomal recessive disorder that inhibits the conversion of phenylalanine to tyrosine. A form of Down syndrome, trisomy 21, is an example of a disorder caused by chromosomal translocation. Cri du chat is an example of a disorder caused by chromosomal deletion. Hemophilia A is an example of a disorder caused by an X-linked recessive gene.

CN: Physiological adaptation; CL: Apply

22. 4. Although it is not known how long diet therapy must continue for children with PKU, many experts suggest continuing it indefinitely because of academic difficulties and lower intelligence quotients in older children who have stopped the restrictive diet. For women, it is necessary to resume the diet before conception to lower the phenylalanine levels in the fetus and

prevent complications.

CN: Physiological adaptation; CL: Synthesize

23. 2. PKU is considered a chronic illness. Parents typically grieve about the loss of health in their child afflicted with a chronic disease. Many times, they repeat questions, as though trying to deny what is really happening. This type of behavior represents an attempt to integrate the experience and their feelings with their self-image as they pass through the grieving process. Asking for detailed explanations, testing the competence of health workers, and expressing impatience with health workers may explain the parents' behavior, but viewing the behavior as a part of the grieving process is the most plausible explanation.

CN: Psychosocial integrity; CL: Analyze

The Client with Colic

24. 2. Information on the crying pattern of the infant is most helpful in confirming the diagnosis of colic. Typically, the colic attack begins abruptly, with the infant crying loudly and continuously, possibly for hours. The attack may end when the child becomes exhausted. The child also may attain some relief after passing stool or flatus. Often, in an attempt to alleviate the infant's crying, parents try to feed the infant, resulting in overfeeding, leading to discomfort and distention. Asking about the type of formula, sleep position, or position for burping will not provide sufficient information to confirm the diagnosis of colic. However, the nurse can obtain additional information after determining the nature of the crying pattern.

CN: Physiological adaptation; CL: Analyze

25. 1. Infants with colic usually pass normal stools, typically soft and yellowish. Frequent watery stools might indicate diarrhea. Ribbon-like stools are suggestive of a narrowing of the colon or the rectum. Foul-smelling stools by themselves are related to diet. When other symptoms such as large size and protuberant abdomen are present, malabsorption may be possible.

CN: Physiological adaptation; CL: Analyze

26. 2. The nurse needs to provide the parents with support because of the

infant's crying. The parents are stressed and need to be encouraged to get out of the house and arrange for some free time. Although infants need lots of attention and care for the first few months, they do not need the mother's undivided attention. Comparing colic with other problems is inappropriate. Parents have the right to be upset. Although colic usually disappears spontaneously by age 3 months, the nurse should not make any guarantees.

CN: Psychosocial integrity; CL: Synthesize

27. 4. Infants with colic should be burped frequently during and after the feeding. Much of the discomfort of colic appears to be associated with the presence of air in the stomach and the intestines. Frequent burping helps to relieve the air. Infants with colic should be held fairly upright while being fed, to help air rise. The preferred position for burping the infant with colic is to hold the infant at the mother's shoulder so that the infant's abdomen lies on the shoulder. This position causes more pressure to be exerted on the infant's abdomen, leading to a more forceful burp. The child should be placed in an infant seat after feedings.

CN: Physiological adaptation; CL: Evaluate

The Client with Obesity

28. 1. Children aged 2 to 20 years with a BMI-for-age at the 90th percentile are considered overweight. If no other risk factors are present, the family should receive dietary counseling to slow the child's weight gain until an appropriate height for weight is attained. Without intervention, the child may become obese. A **HCP** 📖 who specializes in pediatric weight loss should be considered when the child is obese and has complicating factors. Commercial diet programs alone do not include the necessary monitoring for children, thus are rarely appropriate.

CN: Management of care; CL: Synthesize

29. 4. A 3-day diet history is the best way to accurately assess the child's intake. Children under age 1 year should not drink cow's milk because of the risk of allergy. Children over age 1 year should drink whole milk because skim milk and 2% milk do not contain all the essential fatty acids needed by young children. It is unknown at this time how much formula the child is

actually taking, but an infant should not have more than 6 oz (177.4 mL) of juice per day, and additional water is usually not necessary. If an infant is taking no more than 32 oz (946 mL) of formula per day and is eating some baby food and cereal, additional fluids and frequent feeding should not be necessary.

CN: Health promotion and maintenance; CL: Synthesize

30. 3. A 24-hour recall history is the **best** method to obtain a dietary history from an adolescent. Open-ended questions tend not to provide sufficient details for a nutrition history. By asking what the client plans to eat in the future gives the client an opportunity to report the “right” answer. The nurse obtains the information directly from the client; asking the mother has the potential to undermine trust.

CN: Health promotion; CL: Apply

31. 1. The most common complication of adolescent obesity is its persistence into adulthood. The incidence of gastrointestinal and orthopedic problems, such as Legg-Calvé-Perthes disease and genu valgum (knock knees), is greater for obese adolescents; however, they are not the most common complication. Although psychosocial problems do occur, they are not the most common complication.

CN: Reduction of risk potential; CL: Apply

32. 1. Decreasing the amount of formula given as the infant begins to take solids helps prevent excess caloric intake. Because the infant is receiving calories from the solid foods, the formula no longer needs to provide the infant’s total caloric requirements. Mixing vegetables with formula or breast milk does not allow the child to become accustomed to new textures or tastes. Solid foods should be given with a spoon, not in a bottle. Using a bottle with food allows the infant to ingest more food than is needed. Also, the infant needs to learn to eat from a spoon. A small-bowled spoon is recommended for infants because infants have a tendency to push food out with the tongue. The small-bowled spoon helps in placing the food at the back of the infant’s tongue when feeding.

CN: Basic care and comfort; CL: Create

33. 1. Infants generally do not overeat unless they are urged to do so. Parents should watch for clues indicating that the infant is full—for example, stopping sucking and pushing the nipple out of the mouth. Bottle-feeding instead of breast-feeding is more likely to lead to excessive caloric intake. A demand schedule, rather than a regulated schedule, allows the infant to regulate intake according to individual needs. Normally, giving an infant a regular supplementation of water is unnecessary; the infant's sucking needs can be met by providing a pacifier. Adding more water to the formula than as directed decreases the caloric intake and also places the infant at risk for hyponatremia due to decreased sodium and increased water intake.

CN: Basic care and comfort; CL: Synthesize

The Client with Food Sensitivity

34. 4,1,3,2,5. The child is exhibiting signs of anaphylaxis. The principles of emergency management involve activating EMS when an emergency is first realized. The nurse then follows the priorities of Circulation, Airway, Breathing (C, A, B). The epinephrine should then be given to reduce airway constriction and prevent cardiovascular collapse. The child should be assisted into the most comfortable position to facilitate breathing, usually with the head elevated. Then the nurse can take the child's vital signs to assess the effectiveness of the treatment. Lastly, the nurse should notify the family.

CN: Physiological adaptation; CL: Synthesize

35. 1. Lactose intolerance is not an allergy. Rather, it is caused by the lack of the digestive enzyme lactase. This enzyme, found in the intestines, is necessary for the digestion of lactose, the primary carbohydrate in cow's milk. Protein and fat digestion are not affected.

CN: Physiological adaptation; CL: Evaluate

36. 4. People who are lactose intolerant usually are able to tolerate dairy products in which lactose has been fermented, such as yogurt, cheese, and buttermilk. Pudding, ice cream, and creamed soups contain lactose that has not been fermented.

CN: Physiological adaptation; CL: Evaluate

37. 1. Mothers of infants with *a* cow's milk allergy can continue to breast-feed if they eliminate cow's milk from their diet. It is important to encourage mothers to continue to breast-feed because breast milk is usually the **least** allergenic and most easily digested food for an infant. In addition, the infant is able to obtain protein through the mother's milk. If the mother stops breast-feeding, then a predigested protein hydrolysate formula would be the **first** choice. An iron-fortified formula is a cow's milk-based formula. A soy-based formula is not used because approximately 20% of infants with cow's milk sensitivity are also sensitive to soy. Solid foods are not introduced until the infant is 4 to 6 months of age.

CN: Basic care and comfort; CL: Synthesize

38. 2. Children with lactose intolerance often tolerate small amounts of dairy products better when they are consumed at mealtime with other foods. Most people with lactose intolerance can consume 2 to 4 oz (60 to 120 mL) of milk at a time without symptoms. Larger quantities are more likely to cause gas and bloating. Cheeses contain less lactose than milk and may be better tolerated. Yogurt also contains enzymes that are activated in the duodenum that substitute for natural lactase. Taking supplemental enzymes or drinking lactase-treated milk may also substitute for natural lactase.

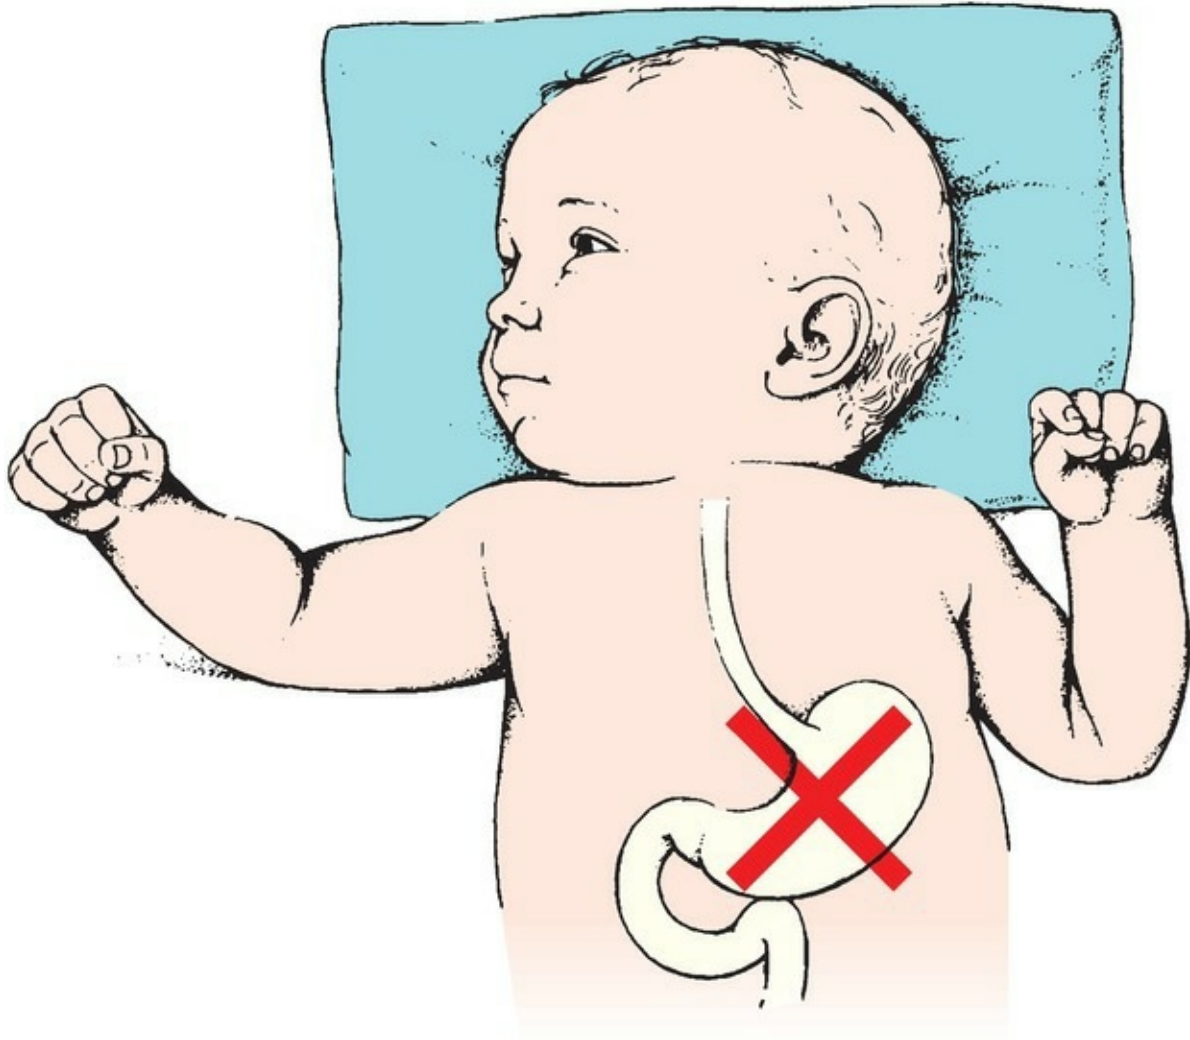

CN: Basic care and comfort; CL: Synthesize

The Client with Failure to Thrive

39. The nasogastric tube should reside in the stomach. The site placement can be verified by inserting 3 to 5 mL of air in the tube and auscultating the infant's abdomen for the sound of air. The nurse should then aspirate the injected air and a small amount of stomach contents and then test the contents for acidity.

CN: Safety and infection control; CL: Apply

40. 3. In the short-term care of this infant, it is important that the same person feed the infant at each meal and that this person be able to assess for negative feeding patterns and replace them with positive patterns. Once the infant is gaining weight and shows progress in the feeding patterns, the parents can be instructed in proper feeding techniques. This is a long-term outcome of nursing care. Because there is no organic reason for the failure to thrive, it should not be necessary to increase the formula calorie content. A 5-month-old infant is too young to be expected to sit in a high chair for feedings and should still be bottle-fed.

 CN: Physiological adaptation; CL: Synthesize

41. 4. The most effective follow-up care would occur in the home environment. The community health nurse can be supportive of the parents

and will be able to observe parent-infant interactions in a natural environment. The community health nurse can evaluate the infant's progress in gaining weight, offer suggestions to the parents, and help the family solve problems as they arise.

CN: Physiological adaptation; CL: Synthesize

Managing Care, Quality, and Safety of Children with Health Problems Involving Ingestion, Nutrition, or Diet

42. 2. For children receiving intermittent gavage feedings, the **best** method to verify the tube placement before each feeding is to aspirate a small amount of gastric contents to verify that the pH is acidic. A pH of 5.5 or less should indicate correct placement in most babies. Depending on the type of feeding tube used, an x-ray may be used to confirm the original tube placement, but use before every feeding would expose the child to unnecessary radiation. Air boluses are misleading because placement in the esophagus or respiratory tract may make the same sound in small infants. Charts might be helpful in determining initial tube insertion length but do not substitute for nursing assessments.

CN: Reduction of risk potential; CL: Apply

43. 2. Public education about the sources of lead that could cause poisoning has been found to be the most effective measure to prevent lead poisoning. This includes recent efforts to alert the public to lead in certain types of window blinds. Condemning old housing developments has been ineffective because lead paint still exists in many other dwellings. Providing education about good nutrition, although important, is not an effective preventive measure. Pregnant women and children should not remain in an older home that is being remodeled because they may breathe in lead in the dust, but this is not the most effective preventive measure.

CN: Safety and infection control; CL: Synthesize

44. 1. Three severe reactions in 3 months indicate a serious problem with adhering to the prevention plan. The nurse should **first** determine if the parent can actually read the label. The underlying problem may be that the parent is visually impaired or unable to read. The parent's reading level

determines what additional support is needed. Referrals to social service or dietary may be indicated, but the nurse does not yet have enough information about the problem. The nurse would communicate with the **HCP** 📖 after assessing the situation to recommend referrals.

CN: Management of care; CL: Synthesize

6

The Child with Health Problems of the Urinary System

- The Client with Cryptorchidism
- The Client with Hydrocele
- The Client with Hypospadias
- The Client with Urinary Tract Infection
- The Client with Glomerulonephritis
- The Client with Nephrotic Syndrome
- The Client with Acute or Chronic Renal Failure
- The Client with Wilms' Tumor
- Managing Care, Quality, and Safety of Children with Health Problems of the Urinary System
- Answers, Rationales, and Test-Taking Strategies

The Client with Cryptorchidism

1. A father brings his 4-week-old son to the clinic for a checkup, stating that he believes his son's testicle is missing. Which explanation would be **most** appropriate?

- ☐ **1.** "Although the testes should have descended by now, it is not a cause for worry."
- ☐ **2.** "It does appear that one of his testes has not descended. I will palpate his scrotum to check whether both testes are present."
- ☐ **3.** "The testes are present in the scrotal sac at birth, but surgery can remedy the situation."
- ☐ **4.** "Although the testes normally descend by 1 year of age, I can understand your concern."

2. While preparing to examine a 6-week-old infant's scrotal sac and testes for possible undescended testes, which would be **most** important for the nurse to do?

- ☐ 1. Check the diaper for recent urination.
- ☐ 2. Give the infant a pacifier.
- ☐ 3. Ensure that the room is kept warm.
- ☐ 4. Tap lightly on the left inguinal ring.

3. While the nurse is examining the infant for presence of testes, the father paces around the room shaking his head. Which statement would be the **most** appropriate response by the nurse?

- ☐ 1. "I am sure everything will work out for the best, and he will be fine."
- ☐ 2. "You seem upset; please tell me how you are feeling."
- ☐ 3. "Do not worry; his testes will probably descend on their own."
- ☐ 4. "Would you like to talk with a parent of a child who has the same problem?"

4. When assessing an infant with an undescended testis, the nurse should be alert for which symptom?

- ☐ 1. abnormal lower extremity reflexes
- ☐ 2. a history of frequent emesis
- ☐ 3. a bulging in the inguinal area
- ☐ 4. poor weight gain

5. When developing the preoperative teaching plan for a 14-month-old child with an undescended testis who is scheduled to have surgery, which method is appropriate?

- ☐ 1. Tell the child that his penis and scrotum will be "fixed."
- ☐ 2. Explain to the parents how the defect will be corrected.
- ☐ 3. Tell the child that he will not see any incisions after surgery.
- ☐ 4. Use an anatomically correct doll to show the child what will be "fixed."

6. An adolescent with a history of surgical repair for an undescended testis comes to the clinic for a sports physical. Which anticipatory guidance for the parents and adolescent is **most** important?

- ☐ 1. the adolescent's sterility
- ☐ 2. the adolescent's future plans
- ☐ 3. technique for monthly testicular self-examinations
- ☐ 4. need for a lot of psychological support

The Client with Hydrocele

7. During a clinic visit, the mother of an infant with hydrocele states that the infant's scrotum is smaller now than when he was born. After teaching the mother about the infant's condition, which statement by the mother indicates that the teaching has been effective?

- ☐ 1. "I guess keeping his bottom up has helped."
- ☐ 2. "Massaging his groin area is working."
- ☐ 3. "It seems like the fluid is being reabsorbed."
- ☐ 4. "Keeping him quiet and in an infant seat has helped."

8. Shortly after an infant is returned to his room following hydrocele repair, the infant's parent approaches the nurse in the hall to report that the child's scrotum looks swollen and bruised. Which response by the nurse would be **most** appropriate?

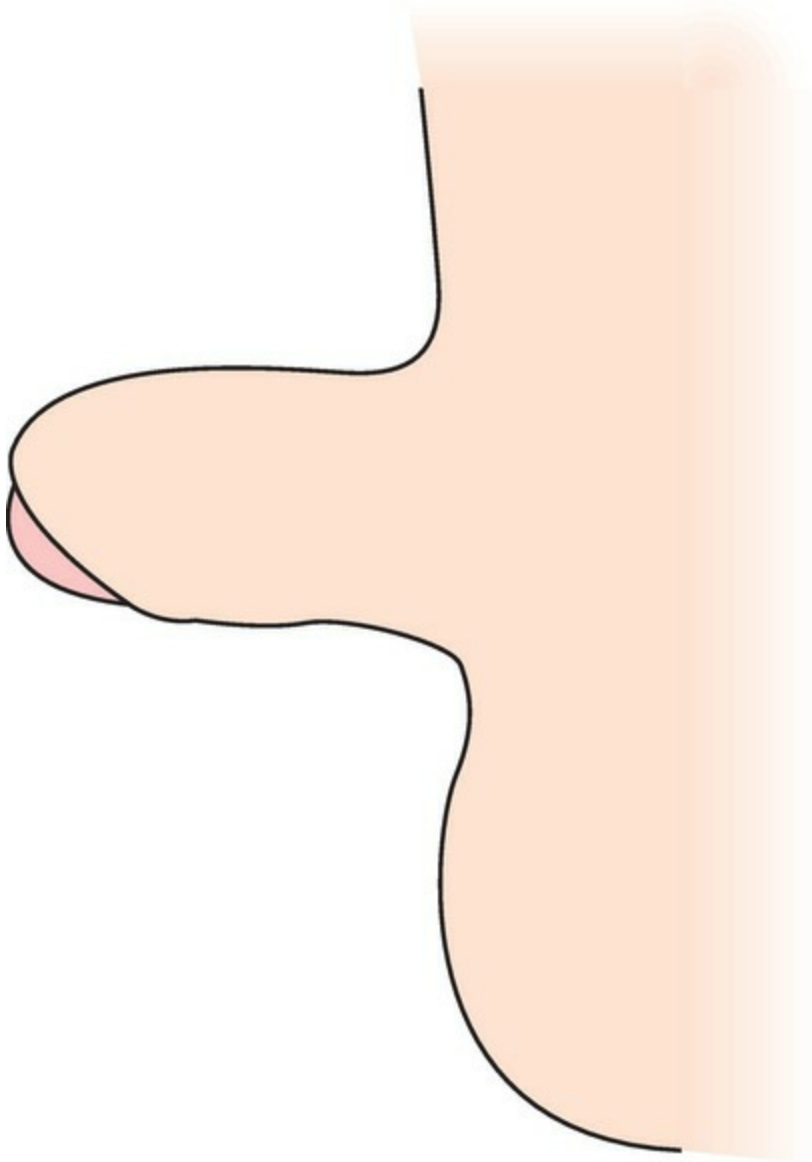

- ☐ 1. "Let me see if the surgeon has prescribed aspirin for him. If he did, I will get it right away."
- ☐ 2. "Can you wait in his room? Then you can ask me any questions when I get there."
- ☐ 3. "What you are describing is unusual after this type of surgery. I will let the surgeon know."
- ☐ 4. "This is normal after this type of surgery. Let us look at it together just to be sure."

The Client with Hypospadias

9. The parents of a neonate with hypospadias and chordee wish to have him circumcised. Which explanation should the nurse incorporate into the discussion with the parents concerning the recommendation to delay circumcision?

- ☐ 1. The associated chordee is difficult to remove during circumcision.
- ☐ 2. The foreskin is used to repair the deformity surgically.
- ☐ 3. The meatus can become stenosed, leading to urinary obstruction.
- ☐ 4. The infant is too small to have a circumcision.

10. The nurse is caring for an infant with hypospadias. Identify the area where the nurse would assess for this condition.

11. A 1-year-old child is scheduled for surgery to correct hypospadias and chordee. The nurse explains to the parents that this is the preferred time for surgical repair based on which factor?

- ☐ 1. At this age, the child will experience less pain.
- ☐ 2. The child is too young to have developed castration anxiety.
- ☐ 3. The child will not remember the surgical experience.
- ☐ 4. The repair is easier to perform after the child is toilet trained.

12. A 6-month-old child is discharged with a urinary stent after a procedure to repair a hypospadias. The nurse should tell the parents to:

- ☐ 1. avoid tub baths until the stent is removed.
- ☐ 2. measure output in the urinary bag.
- ☐ 3. avoid giving fruit juice.
- ☐ 4. clean the tip of the penis three times a day with soap and water.

13. After teaching the parents about the urethral catheter placed after surgical repair of their son's hypospadias, the nurse determines that the teaching was successful when the mother states that the catheter in her child's penis accomplishes which goal?

- ☐ 1. decreases pain at the surgical site
- ☐ 2. keeps the new urethra from closing
- ☐ 3. measures his urine correctly
- ☐ 4. prevents bladder spasms

14. While assessing the penis of a child who has had surgery for repair of a hypospadias, the nurse observes the appearance of the penis. The nurse should report which aspect to the surgeon?

- ☐ 1. swollen
- ☐ 2. dusky blue at the tip
- ☐ 3. somewhat misshapen
- ☐ 4. pink

15. When developing the teaching plan for the parents of a 12-month-old infant with hypospadias and chordee repair, what information is **most** important to include?

- ☐ 1. Assist the child to become familiar with his dressings so he will leave them alone.
- ☐ 2. Encourage the child to ambulate as soon as possible by using a favorite push toy.

- ☐ 3. Force fluids to at least 2,500 mL/day by offering his favorite juices.
- ☐ 4. Prevent the child from disrupting the catheters by using soft restraints.

16. The healthcare provider (HCP) prescribes a urinalysis for a child who has undergone surgical repair of a hypospadias. Which results should the nurse report to the HCP?

- ☐ 1. urine specific gravity of 1.017
- ☐ 2. ten red blood cells per high-powered field
- ☐ 3. twenty-five white blood cells per high-powered field
- ☐ 4. urine pH of 6.0

The Client with Urinary Tract Infection

17. A teenage girl has been diagnosed with a urinary tract infection. The nurse recognizes the need for teaching when the teenager states:

- ☐ 1. "I will not take bubble baths."
- ☐ 2. "I will drink plenty of water."
- ☐ 3. "I can drink coffee."
- ☐ 4. "I can drink cranberry juice."

18. A 4-year-old with a history of urinary reflux returned from surgery for bilateral urethral reimplants 2 days ago. Which assessment finding is **most** concerning?

- ☐ 1. intermittent bladder spasms
- ☐ 2. small amounts of blood-tinged urine
- ☐ 3. decreased oral intake
- ☐ 4. continuous drainage from a Foley catheter

19. The healthcare provider (HCP) has prescribed a sterile urine specimen for a 3-year-old boy with a history of recurrent urinary tract infections. The family is upset because the last time the child was catheterized, the procedure was very painful and traumatic. The nurse should tell the family:

- ☐ 1. "I will request a prescription for a sedative to help him relax."
- ☐ 2. "I cannot do anything to reduce the pain, but you can hold him during the procedure."
- ☐ 3. "I will get a prescription for a lidocaine lubricant with numbing

medicine to make the procedure more comfortable.”

☐ 4. “I can apply a topical anesthetic 20 minutes before placing the catheter.”

20. The parents of a child on sulfamethoxazole and trimethoprim for a urinary tract infection report that the child has a red, blistery rash. The nurse should tell the parents to:

- ☐ 1. apply lotion to the affected areas.
- ☐ 2. discontinue the medicine and come for immediate further evaluation.
- ☐ 3. use sunblock while on the medication.
- ☐ 4. increase the child’s fluid intake.

21. A recent history of which problem should alert the nurse to gather additional information about the possibility of a urinary tract infection in a 2-year-old child who is exhibiting fever and fussiness?

- ☐ 1. abdominal pain
- ☐ 2. swollen lymph glands
- ☐ 3. skin rash
- ☐ 4. back pain

22. A father of a child with a urinary tract infection calls the clinic and explains, “My wife and I are concerned because our child refuses to obey us concerning the preventions you told us about. Our child refuses to take the medication unless we buy a present. We do not want to use discipline because of the illness, but we are worried about the behavior.” Which response by the nurse is **best**?

- ☐ 1. “I sympathize with your difficulties, but just ignore the behavior for now.”
- ☐ 2. “I understand it is hard to discipline a child who is ill, but things need to be kept as normal as possible.”
- ☐ 3. “I understand that things are difficult for you right now, but your child is ill and deserves special treatment.”
- ☐ 4. “I understand your concern, but this type of behavior happens all the time; your child will get over it when feeling better.”

23. A nurse is teaching the parents of a child diagnosed with a urinary tract

infection secondary to vesicoureteral reflux. How should the nurse explain how the reflux contributes to the infection?

- ☐ 1. "It prevents complete emptying of the bladder."
- ☐ 2. "It causes urine backflow into the kidney."
- ☐ 3. "It results in painful bladder spasms."
- ☐ 4. "It causes painful urination."

The Client with Glomerulonephritis

24. A 15-year-old has been diagnosed with acute glomerulonephritis and has been in the hospital for 1 day. Which finding requires **immediate** action?

- ☐ 1. large amount of generalized edema
- ☐ 2. urine specific gravity of 1.030
- ☐ 3. large amount of albumin in the urine
- ☐ 4. 24-hour output of 1,500 mL

25. Which meal would be **most** appropriate for a 15-year-old with glomerulonephritis with severe hypertension?

- ☐ 1. egg noodles, hamburger, canned peas, milk
- ☐ 2. baked ham, baked potato, pear, canned carrots, milk
- ☐ 3. baked chicken, rice, beans, orange juice
- ☐ 4. hot dog on a bun, corn chips, pickle, cookie, milk

26. A 10-year-old with glomerulonephritis reports a headache and blurred vision. The nurse should **immediately**:

- ☐ 1. put the client to bed.
- ☐ 2. obtain the child's blood pressure.
- ☐ 3. notify the healthcare provider (HCP).
- ☐ 4. administer acetaminophen.

27. Which question should the nurse ask **first** when obtaining a history from the mother of a 10-year-old child with a fever, malaise, and swelling around the eyes?

- ☐ 1. "Has the child had a sore throat recently?"
- ☐ 2. "Is the child playing with friends as usual?"

- ☐ 3. “Does the child urinate as much as usual?”
- ☐ 4. “Is the urine pale in color?”

28. A school-age client admitted to the hospital because of decreased urine output and periorbital edema is diagnosed with acute poststreptococcal glomerulonephritis. Which assessment gives the nurse the **best** indication of the child’s fluid balance?

- ☐ 1. Assess vital signs every 4 hours.
- ☐ 2. Monitor intake and output every 12 hours.
- ☐ 3. Obtain daily weight measurements.
- ☐ 4. Obtain serum electrolyte levels daily.

29. When developing the plan of care for a school-age child with acute poststreptococcal glomerulonephritis who has a fluid restriction of 1,000 mL/day, which fluid should the nurse consider as **most** appropriate for the client’s condition and effective for preventing excessive thirst?

- ☐ 1. diet cola
- ☐ 2. ice chips
- ☐ 3. lemonade
- ☐ 4. tap water

30. The nurse is planning interventions for a school-age child hospitalized with acute poststreptococcal glomerulonephritis in need of diversional activity. Which activity should the nurse expect to include?

- ☐ 1. playing a card game with someone the same age
- ☐ 2. putting together a puzzle with mother
- ☐ 3. playing video games with a 4-year-old
- ☐ 4. watching a movie with a younger brother

31. A 10-year-old child hospitalized with acute poststreptococcal glomerulonephritis during the acute stage has elevated blood pressure and low urine output for 14 hours. The nurse should **next**:

- ☐ 1. assess the child’s neurologic status.
- ☐ 2. encourage the child to drink more water.
- ☐ 3. advise the child to eat a low-sodium breakfast.
- ☐ 4. help the client to ambulate in the hallway.

32. When developing the discharge plan for a school-age child diagnosed with acute poststreptococcal glomerulonephritis, which instruction should the nurse plan to discuss?

- ☐ 1. Restrict dietary protein.
- ☐ 2. Monitor pulse rate and rhythm.
- ☐ 3. Prevent respiratory infections.
- ☐ 4. Restrict foods high in potassium.

33. An adolescent with a history of losing weight and fatigue is admitted to the hospital with a diagnosis of stage I chronic renal failure. The chart shows:

Intake and Output	
Day 1: Intake 1,850 mL	Output 1,550 mL
Day 2: Intake 2,200 mL	Output 1,150 mL

Based on these findings, the nurse should:

- ☐ 1. continue monitoring intake and output.
- ☐ 2. notify the healthcare provider (HCP).
- ☐ 3. restrict the client's fluids.
- ☐ 4. increase the client's fluids.

34. A parent of a child with acute poststreptococcal glomerulonephritis (APSGN) asks how a strep infection caused the child to have a kidney problem. What is the nurse's **best** response?

- ☐ 1. "The streptococcal infection spread through the bloodstream to your child's kidneys."
- ☐ 2. "Your child made excessive antibodies to fight the infection that are now attacking the kidneys."
- ☐ 3. "By-products of immune complexes that fought the infection are depositing in the kidneys."

- ☐ 4. “The strep infection weakened your child’s immune system, making him susceptible to a secondary infection.”

The Client with Nephrotic Syndrome

35. A child with nephrosis is taking prednisone. The nurse should teach the caregivers to report which adverse effects? Select all that apply.

- ☐ 1. increased urinary output
☐ 2. hematemesis
☐ 3. respiratory infection
☐ 4. bleeding gums
☐ 5. vision problems

36. The nurse is caring for a 5-year-old boy who is taking prednisolone for nephrotic syndrome. The child is at the 75th percentile for height and has a blood pressure of 114/73 mm Hg. The nurse compares the reading to the below blood pressure levels for boys age and height percentiles.

The nurse determines that the blood pressure represents a change and notifies the healthcare provider (HCP) of the assessment of:

- ☐ 1. hypotension.
☐ 2. prehypertension.
☐ 3. hypertension.
☐ 4. hypertension stage II.

Systolic BP Reading								Diastolic BP Reading						
←Percentile for Height→								←Percentile for height→						
Age														
Percentile	5 th	10 th	25 th	50 th	75 th	90 th	95 th	5 th	10 th	25 th	50 th	75 th	90 th	95 th
50th	90	91	93	95	96	98	98	50	51	52	53	54	55	55
90th	104	105	106	108	110	111	112	65	66	67	68	69	69	70
95th	108	109	110	112	114	115	116	69	70	71	72	73	74	74
99th	115	116	118	120	121	123	123	77	78	79	80	81	81	82

37. The charge nurse is reviewing the laboratory results of a child admitted

with nephrotic syndrome with a nurse new to the pediatric unit. The nurse is aware that teaching is required when the new nurse states that an expected finding in nephrotic syndrome is:

- ☐ 1. hyperalbuminemia.
- ☐ 2. elevated triglycerides.
- ☐ 3. elevated cholesterol.
- ☐ 4. proteinuria.

38. Which statement by the parent of a toddler diagnosed with nephrotic syndrome indicates that the parent has understood the nurse's teaching about this disease?

- ☐ 1. "My child really likes chips and bologna. I guess we will have to find something else."
- ☐ 2. "We will have to encourage lots of liquids. Did you say about 4 L every day?"
- ☐ 3. "We worry about the surgery. Do you think we should do direct donation of blood?"
- ☐ 4 "We understand the need for antibiotics. I just wish the antibiotics could be given by mouth."

39. A toddler diagnosed with nephrotic syndrome has a fluid volume excess related to fluid accumulation in the tissues. Which measure should the nurse anticipate including in the child's plan of care?

- ☐ 1. Limit visitors to 2 to 3 hours a day.
- ☐ 2. Maintain strict bed rest.
- ☐ 3. Test urine specific gravity every shift.
- ☐ 4. Weigh the child before breakfast.

40. The parent of a toddler with nephrotic syndrome asks the nurse what can be done about the child's swollen eyes. Which measure should the nurse suggest?

- ☐ 1. Apply cool compresses to the child's eyes.
- ☐ 2. Elevate the head of the child's bed.
- ☐ 3. Apply eyedrops every 8 hours.
- ☐ 4. Limit the child's television watching.

41. The nurse determines that interventions for decreasing fluid retention have been effective when the nurse makes which assessment in a child with nephrotic syndrome?

- ☐ 1. decreased abdominal girth
- ☐ 2. increased caloric intake
- ☐ 3. increased respiratory rate
- ☐ 4. decreased heart rate

42. The toddler with nephrotic syndrome exhibits generalized edema. Which measure should the nurse institute for this child with impaired skin integrity related to edema?

- ☐ 1. Ambulate every shift while awake.
- ☐ 2. Apply lotion on opposing skin surfaces.
- ☐ 3. Apply powder to skinfolds.
- ☐ 4. Separate opposing skin surfaces with soft cloth.

43. A child with nephrosis is placed on prednisone. The dose is 2 mg/kg/day to be administered twice a day. The child weighs 25 lb (11.3 kg). How many milligrams will the child receive at each dose? Record your answer using one decimal place.

_____ mg.

44. The toddler with nephrotic syndrome responds to treatment and is ready to go home. When helping the family plan for home care, which instruction should the nurse include in the teaching?

- ☐ 1. Administer pain medication as needed.
- ☐ 2. Keep the child away from others with an infection.
- ☐ 3. Notify the healthcare provider (HCP) if there is an increase in the child's urine output.
- ☐ 4. Administer acetaminophen daily.

The Client with Acute or Chronic Renal Failure

45. The nurse is planning care with the parents of a child who requires continuous peritoneal dialysis. Which finding should be discussed with the

healthcare provider (HCP)?

- ☐ 1. The family lives a long distance from the medical facility.
- ☐ 2. The child attends a large public school.
- ☐ 3. The child reports having a previous surgery for a ruptured appendix.
- ☐ 4. The family feels the child cannot self-regulate to wake at night and change bags.

46. While performing daily peritoneal dialysis and catheter exit site care with the mother of a child with chronic renal failure, which information would be an important step to emphasize to the mother?

- ☐ 1. Apply an occlusive dressing after cleaning the site.
- ☐ 2. Change the dressing when the peritoneal space is dry.
- ☐ 3. Examine the site for signs of infection while cleaning the area.
- ☐ 4. Pull on the catheter to hold taut while cleaning the skin.

47. When developing the discharge teaching plan for a child with chronic renal failure and the family, the nurse should emphasize restriction of which nutrient?

- ☐ 1. ascorbic acid
- ☐ 2. calcium
- ☐ 3. magnesium
- ☐ 4. phosphorus

48. After emphasizing to an adolescent with renal failure the importance of maintaining a positive self-concept, which behavior by the adolescent should the nurse identify as an indicator that the plan is working?

- ☐ 1. reports of headaches, abdominal pain, and nausea
- ☐ 2. insistence on making diet choices even if the foods chosen are restricted
- ☐ 3. verbalization of plans to quit all after-school activities when returning home
- ☐ 4. demonstration of desire to do the dressing changes and take care of the medications

49. Which diet plan would be appropriate for the nurse to discuss with the family of a child with acute renal failure?

- ☐ 1. high carbohydrate and protein
- ☐ 2. high fat and carbohydrate
- ☐ 3. low fat and protein
- ☐ 4. low carbohydrate and fat

50. An adolescent with chronic renal failure is scheduled to go home with a peritoneal dialysis catheter in place. When developing the discharge teaching plan for the client and the family focusing on psychosocial needs, which area should be a **priority** to include?

- ☐ 1. advantages of limiting social activities and contacts for the first few months
- ☐ 2. not disclosing information about the peritoneal dialysis to people outside the family
- ☐ 3. possible effect on body image of the presence of an abdominal catheter
- ☐ 4. importance of relying on parents to do the dialysis and dressing changes

51. During a home visit, the public health nurse assesses the peritoneal catheter exit site of a child with chronic renal failure. Which finding should lead the nurse to determine a client has an infection?

- ☐ 1. dialysate leakage
- ☐ 2. granulation tissue
- ☐ 3. increased time for drainage
- ☐ 4. tissue swelling

52. After teaching the parent of a young child with a peritoneal catheter about the signs and symptoms of peritonitis, the nurse determines that the parent has understood the teaching when she identifies which finding as an important sign?

- ☐ 1. cloudy dialysate drainage return
- ☐ 2. distended abdomen
- ☐ 3. shortness of breath
- ☐ 4. weight gain of 3 lb (1.36 kg) in 2 days

53. The nurse assesses the child with chronic renal failure who is receiving peritoneal dialysis for edema. Which finding is expected for this child?

- ☐ 1. absence of pulmonary crackles
- ☐ 2. increased dialysate outflow
- ☐ 3. normal blood pressure
- ☐ 4. pallor

54. The parent of a child with chronic renal failure who is receiving peritoneal dialysis at home asks the nurse what she can do if both inflow and drain times are increased. Which instructions would be **most** appropriate for the nurse to include when responding to the parent?

- ☐ 1. Assess the child for constipation.
- ☐ 2. Decrease the amount of dialysate infused for each dwell.
- ☐ 3. Incorporate the increased inflow and drain times into the dialysis schedule.
- ☐ 4. Monitor the child for shoulder pain during inflow and drain times.

55. The nurse judges that the mother understands the diet restrictions for her child with chronic renal failure who is receiving peritoneal dialysis when she reports providing a diet involving which components?

- ☐ 1. sodium and water restrictions
- ☐ 2. high protein and carbohydrates
- ☐ 3. high potassium and iron
- ☐ 4. protein and phosphorous restrictions

The Client with Wilms' Tumor

56. A 3-year-old child receiving chemotherapy after surgery for a Wilms' tumor has developed neutropenia. The parent is trying to encourage the child to eat by bringing extra foods to the room. Which food would **not** be appropriate for this child?

- ☐ 1. fudge
- ☐ 2. French fries
- ☐ 3. fresh strawberries
- ☐ 4. a milk shake

57. When assessing a 2-year-old child with Wilms' tumor, what should the nurse avoid?

- ☐ 1. measuring the child's chest circumference
- ☐ 2. palpating the child's abdomen
- ☐ 3. placing the child in an upright position
- ☐ 4. measuring the child's occipitofrontal circumference

58. Which statement by the parent of a child with Wilms' tumor tells the nurse that the parent understands what *stage II tumor* means?

- ☐ 1. "The tumor has extended beyond the kidney but was completely removed."
- ☐ 2. "Although the tumor was in the kidney, it has spread to the lung, liver, and bone."
- ☐ 3. "The tumor has extended outside the kidney to the lungs and the liver."
- ☐ 4. "The tumor was solely located in the kidney, but it was totally removed."

59. A child diagnosed with Wilms' tumor undergoes successful surgery for removal of the diseased kidney. When the child returns to the room, the nurse should place the child in which position?

- ☐ 1. modified Trendelenburg
- ☐ 2. Sims'
- ☐ 3. semi-Fowler's
- ☐ 4. supine

60. After a child undergoes nephrectomy for a Wilms' tumor, the nurse should assess the child postoperatively for which early sign of a - complication?

- ☐ 1. increased abdominal distention
- ☐ 2. elevated blood pressure
- ☐ 3. increased respiratory rate
- ☐ 4. increased urine output

61. When developing the discharge plan for a child who had a nephrectomy for a Wilms' tumor, the nurse identifies outcomes to prevent damage to the child's remaining kidney and to accomplish which goal?

- ☐ 1. Minimize pain.
- ☐ 2. Prevent dependent edema.

- ☐ 3. Prevent urinary tract infection.
- ☐ 4. Minimize sodium intake.

Managing Care, Quality, and Safety of Children with Health Problems of the Urinary System

62. The nurse reads the new medication prescriptions for a 4-year-old child with nephrotic syndrome on the chart below:

Prescriptions

D/C prednisolone 40 mg PO Daily
Prednisolone 30 mg PO QOD

The nurse should:

- ☐ 1. discontinue the prednisolone 40 mg and give the 30-mg dose today.
- ☐ 2. check the medication record first to see when the last dose of prednisolone was given.
- ☐ 3. start the 30-mg dose tomorrow.
- ☐ 4. contact the prescriber for clarification.

63. The charge nurse finds the mother of a child with a chronic bladder condition requiring clean intermittent catheterization (CIC) visibly upset. The mother states, “That other nurse said parents are not allowed to perform CIC in the hospital because of increased infection risk.” The charge nurse should tell the parent:

- ☐ 1. “Your child is exposed to additional bacterial in the hospital that makes CIC unsafe.”
- ☐ 2. “You can catheterize your child as long as you use sterile technique.”
- ☐ 3. “You can use CIC on your child. I will talk with your nurse to clarify the policy.”
- ☐ 4. “I can tell you are having a conflict with this nurse. I will switch

assignments.”

64. The parent of an 18-year-old with chronic renal disease states, “My son has so many problems. I am really worried that he will not get the right care if he gets sick at college.” The nurse should tell the parent:

- ☐ 1. “I can have his records sent to the school’s health center.”
- ☐ 2. “Make sure your son always carries his nephrologist’s phone number.”
- ☐ 3. “Your son can make an e-health history to facilitate his care if he gets sick away from home.”
- ☐ 4. “Your son is going to need to learn to manage his own disease.”

Answers, Rationales, and Test-Taking Strategies

*The answers and the rationales for each question follow below, along with keys (🔑) to the client need (CN) and cognitive level (CL) for each question. In addition, you will also see a glossary icon (📖) highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 12–23 and pages 35–36 in Part 1 of this book.*

The Client with Cryptorchidism

1. 4. Normally, the testes descend by 1 year of age; failure to do so may indicate a problem with patency or a hormonal imbalance. By age 4 weeks, descent may not have occurred. However, telling the father that lack of descent is not a cause for worry is inappropriate and uncaring. Additionally, a statement such as this may be false reassurance. By acknowledging the father’s concern, the nurse indicates acceptance of his feelings. If the testes have not descended, then they will not be palpable in the scrotal sac. Surgery is not discussed until after a full assessment is completed.

CN: Health promotion and maintenance; CL: Synthesize

2. 3. A cold environment can cause the testes to retract. Cold and touch

stimulate the cremasteric reflex, which causes a normal retraction of the testes toward the body. Therefore, the nurse should warm the hands and make sure that the environment also is warm. Checking the diaper for urination provides information about the infant's voiding and urinary function, not information about the testes. Giving the infant a pacifier may help to calm the infant and possibly make the examination easier, but the concern here is with the temperature of the environment. Tapping on the inguinal ring would not be helpful in assessing the infant.

CN: Health promotion and maintenance; CL: Synthesize

3. 2. The nurse needs more information about the father's perceptions and feelings before providing any information or taking action. Determining the exact nature of the father's concern rather than making an assumption about it is essential. Therefore, the nurse should identify what is observed and ask the father how he is feeling. Telling the father that everything will be fine or not to worry is inappropriate and provides false reassurance. It also devalues the father's concern. Later on, it may be appropriate for the father to talk to a parent of a child with the same problem for support.

CN: Psychosocial integrity; CL: Synthesize

4. 3. When an anomaly is found in one system, such as the genitourinary system, that system requires a more focused assessment to reveal other conditions that also may be occurring. A bulging in the inguinal area may suggest an inguinal hernia. Also, hydrocele or an upper urinary tract anomaly may occur on the same side as the undescended testis. A neuromuscular problem, not a genitourinary problem such as undescended testes, would most likely be the cause of abnormal lower extremity reflexes. A history of frequent emesis may be caused by pyloric stenosis or viral gastroenteritis. Poor weight gain might suggest a metabolic or a feeding problem.

CN: Health promotion and maintenance; CL: Analyze

5. 2. Preoperative teaching would be directed at the parents because the child is too young to understand the teaching. Telling the child that his penis and scrotum will be "fixed," telling the child he will not see incisions after surgery, and using a doll to illustrate the surgery are appropriate interventions for a preschool-age child.

 CN: Psychosocial integrity; CL: Create

6. 3. Because the incidence of testicular cancer is increased in adulthood among children who have had undescended testes, it is extremely important to teach the adolescent how to perform the testicular self-examination monthly. The undescended testicle is removed to reduce the risk of cancer in that testicle. Removal of a testis would not necessarily make the adolescent sterile because the other testicle remains. Although discussing the adolescent's future plans is important, it is not the priority at this time. Because the adolescent has been dealing with the situation for a long time, the need for a sports physical at this time should not be a cause of emotional distress requiring a lot of psychological support.

 CN: Health promotion and maintenance; CL: Synthesize

The Client with Hydrocele

7. 3. A hydrocele is a collection of fluid in the tunica vaginalis of the testicle or along the spermatic cord that results from a patent processus vaginalis. As fluid is being absorbed, scrotal size decreases. Elevation of the infant's bottom, massage, or keeping the infant quiet or in an infant seat would have no effect in promoting fluid reabsorption in hydrocele.

 CN: Physiological adaptation; CL: Evaluate

8. 4. Some swelling and bruising are normal postoperatively. By assessing the area with the mother, the nurse is conveying acceptance of the mother's concern. In addition, the nurse needs to inspect the area to determine if what the mother is describing is accurate. Doing so also provides an opportunity for teaching. Aspirin is not usually prescribed for children because of the link between aspirin and Reye's syndrome. Acetaminophen is commonly administered for fever or pain relief. Asking the mother to wait in the child's room ignores the mother's concerns. There is no need to notify the surgeon at this time.

 CN: Psychosocial integrity; CL: Synthesize

The Client with Hypospadias

9.2. The condition in which the urethral opening is on the ventral side of the penis or below the glans penis is referred to as *hypospadias*. *Chordee* refers to a ventral curvature of the penis that results from a fibrous band of tissue that has replaced normal tissue. Circumcision is delayed because the foreskin, which is removed with a circumcision, often is used to reconstruct the urethra. The chordee is corrected when the hypospadias is repaired. Circumcision is performed at the same time. Urethral meatal stenosis, which can occur in circumcised infants, results from meatal ulceration, possibly leading to urinary obstruction. It is not associated with hypospadias or circumcision. The infant is not too small to have a circumcision, which is commonly performed on the first or the second day of life.

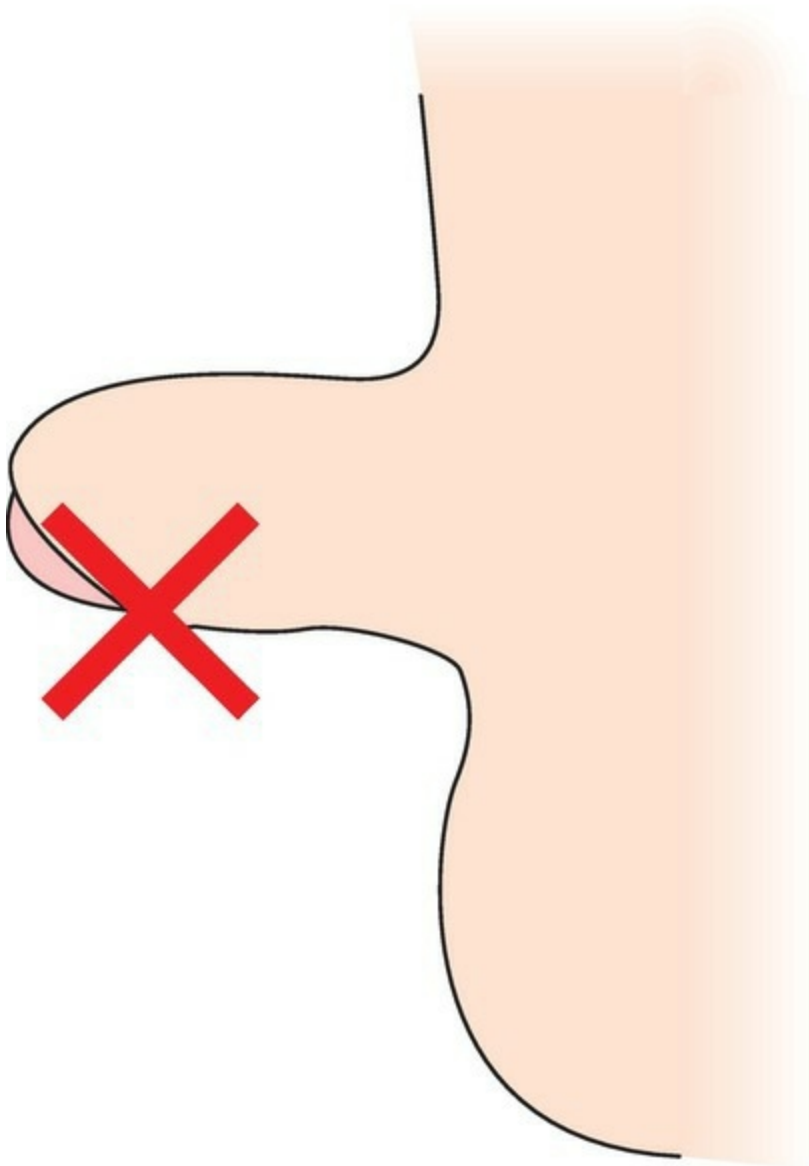

CN: Reduction of risk potential; CL: Apply

10. In hypospadias, the urethral opening is on the ventral side of the penis.

CN: Physiological adaptation; CL: Apply

11. 2. The preferred time for surgery is between the ages of 6 and 18 months, before the child develops castration and body image anxiety. Children learn early on about society's emphasis on the importance of genitals. Pain is different for each child and is not related to the preferred time for repair of the hypospadias or chordee. Although the child will probably not remember the experience, this is not the basis for having the surgery at this age. If the condition is not repaired, the child will have difficulty with toilet training because urine is not eliminated through the tip of the penis.

CN: Physiological adaptation; CL: Apply

12. 1. The parents should keep the penis as dry as possible until the stent is removed. Soaking in a tub bath is not recommended. Children this age typically go home voiding directly into a diaper. Infants may be started on juice at 6 months of age. Parents are advised to keep their child well hydrated after a hypospadias repair. Therefore, there is no reason to avoid juice. Cleaning the tip of the penis three times a day may cause unnecessary irritation.

CN: Safety and infection control; CL: Synthesize

13. 2. The main purpose of the urethral catheter is to maintain patency of the reconstructed urethra. The catheter prevents the new tissue inside the urethra from healing on itself. However, the urethral catheter can cause bladder spasms. Recently, stents have been used instead of catheters. The urethral catheter will have no effect on the child's pain level. In fact, because bladder spasms are associated with its use, the child's problems of pain may actually increase. Urine output can be measured through the suprapubic catheter because it provides an alternative route for urinary elimination, thus keeping the bladder empty and pressure-free.

CN: Reduction of risk potential; CL: Evaluate

14. 2. A dusky blue color at the tip of the penis may indicate a problem with circulation, and the nurse should notify the surgeon. Following surgery, it is normal for the penis to be swollen and pink. The penis may be misshapen and is unlikely to look normal even after reconstruction.

CN: Physiological adaptation; CL: Analyze

15. 4. The most important consideration for a successful outcome of this surgery is maintenance of the catheters or stents. A 12-month-old infant likes to explore his environment but must be prevented from manipulating his dressings or catheters through the use of soft restraints. Allowing the infant to become familiar with the dressings will not prevent him from pulling at them. After surgery the child is allowed limited activity, possibly while sitting in the parent's lap. A 12-month-old infant may or may not be walking. If he is, most likely he will be clumsy and possibly injure himself. Although increasing fluids is important, 2,500 mL/day is an excessive amount for a 12-month-old. Fluid requirements would be 115 mL/kg.

 CN: Physiological adaptation; CL: Create

16. 3. A normal white blood cell count in a urinalysis is 1 to 2 cells/mL. A white blood cell count of 25 per high-powered field indicates a urinary tract infection. A urine specific gravity of 1.017 is within the normal range of 1.002 to 1.030. After urologic surgery, it is not unusual for a small number of red blood cells to appear in the urine. The child's urine pH is within the normal range of 4.6 to 8.

 CN: Reduction of risk potential; CL: Analyze

The Client with Urinary Tract Infection

17. 3. Drinking coffee and other beverages that contain caffeine can irritate the bladder and should be avoided. Bubble baths, bath oils, and hot tubs can irritate the urethra and perineal area. Drinking plenty of water will keep urine flushed through the bladder. Cranberry juice helps to acidify the urine.

 CN: Health promotion and maintenance; CL: Evaluate

18. 3. Children with bilateral ureteral implants often have pain with urination due to bladder spasms. Some children will avoid drinking in order to avoid the pain associated with urination, thus putting the child at risk for dehydration. Intermittent bladder spasms are common after ureteral reimplant surgery and can be treated with oxybutynin to decrease discomfort. Small amounts of blood-tinged urine, bladder spasms, urinary frequency, and urinary incontinence are common following ureteral reimplant surgery.

 CN: Physiological adaptation; CL: Analyze

19. 3. Two percent lidocaine lubricants have been found to significantly reduce the pain of urinary catheter insertion in children. If the unit does not have a standing protocol to use the lubricant, the nurse should request a prescription. A sedative would carry with it additional risks that could be avoided with the use of other methods to reduce pain. The parents should be encouraged to hold the child in addition to other pain relief methods. Frequent urination would make the use of topical anesthetics that must be left in place for a period of time impractical.

 CN: Basic care and comfort; CL: Synthesize

20. 2. Sulfonamides have been associated with severe adverse reactions. A blistering rash may be a sign of Stevens-Johnson syndrome, a severe allergic reaction that manifests as skin lesions. This reaction is life threatening and requires immediate attention. Lotion should not be applied to skin with blisters. Sulfamethoxazole and trimethoprim may cause photosensitivity, but this usually appears as a mild red rash, not blisters. Increasing the child's fluid intake may help the urinary tract infection, but does not address the rash.

 CN: Pharmacological and parenteral therapies; CL: Synthesize

21. 1. Abdominal pain frequently accompanies urinary tract infection in children 2 years of age and older. Other associated signs and symptoms include decreased appetite, vomiting, fever, and irritability. The presence of swollen lymph glands (lymphadenopathy) is unrelated to urinary tract infections. Lymphadenopathy is associated with a systemic infection or possibly cancer. Skin rash is associated with exposure to allergens or irritants (e.g., poison ivy or harsh soaps); prolonged contact with urine (e.g., diaper dermatitis); or illnesses such as measles, rheumatic fever, or juvenile rheumatoid arthritis. Flank or back pain is associated with urinary tract infection in children older than 2 years of age and in adults.

 CN: Physiological adaptation; CL: Analyze

22. 2. To ensure appropriate psychosocial development, a child needs to have normal patterns maintained as much as possible during illness. It is tempting to give ill children special treatment and to relax discipline. However, family routines and discipline should be kept as normal as possible. The child needs to know the limits to ensure feelings of security. When they are ill, children commonly attempt to stretch the rules and limits. If this occurs, returning to the previous well-behavior patterns will take time.

 CN: Health promotion and maintenance; CL: Synthesize

23. 1. The reason that urinary tract infections are a problem in children with vesicoureteral reflux is that urine flows back up the ureter, past the incompetent valve, and back into the bladder after the child has finished

voiding. This incomplete emptying of the bladder results in stasis of urine, providing a good medium for bacterial growth and subsequent infection. Vesicoureteral reflux does not cause bladder spasms or painful urination. However, the child may experience painful urination with a urinary tract infection.

CN: Physiological adaptation; CL: Apply

The Client with Glomerulonephritis

24. 2. An adolescent with acute glomerulonephritis has a high urine specific gravity related to oliguria caused by inflammation of the glomeruli. The client will have periorbital edema, but not the generalized edema that occurs in nephrotic syndrome. In glomerulonephritis, there is some albumin in the urine, but there are large amounts of red blood cells, giving the urine a brown color. The urine in glomerulonephritis is scanty, averaging about 400 mL in 24 hours, which leads to fluid volume excess and hypertension.

CN: Physiological adaptation; CL: Synthesize

25. 3. The best selection of food would include no added salt or salty food. Because sodium cannot be excreted due to the oliguria and to avoid increasing the hypertension, a low-salt diet is recommended. Most canned foods have sodium added as a preservative. Ham, hot dogs, canned peas, canned carrots, corn chips, pickles, and milk are high in sodium.

CN: Health promotion and maintenance; CL: Synthesize

26. 2. Hypertension occurs with acute glomerulonephritis. The symptoms of headache and blurred vision may indicate an elevated blood pressure. Hypertension in acute glomerulonephritis occurs due to the inability of the kidneys to remove fluid and sodium; the fluid is reabsorbed, causing fluid volume excess. The nurse must verify that these symptoms are due to hypertension. Calling the **HCP**  before confirming the cause of the symptoms would not facilitate his treatment. Putting the client to bed may help treat an elevated blood pressure, but first, the nurse must establish that high blood pressure is the cause of the symptoms. Administering acetaminophen for high blood pressure is not recommended.

 CN: Physiological adaptation; CL: Synthesize

27. 3. Most likely, the nurse suspects that the child is exhibiting signs and symptoms of glomerulonephritis, such as periorbital edema and fever. Other signs and symptoms include loss of appetite, dark-colored urine, pallor, headaches, and abdominal pain. To confirm this suspicion, the nurse would ask about the child's urinary elimination patterns. Typically, the child with glomerulonephritis experiences a decrease in urine output. Asking about any recent sore throat would provide additional information to confirm the suspicion of glomerulonephritis, because the most common type is acute poststreptococcal glomerulonephritis, which follows a strep throat by 10 to 14 days. Frequently, the children have only mild cold symptoms and do not realize they have a streptococcal infection. Asking whether the child plays with friends as usual is important and gives the nurse information about how the child feels in general. However, this is a general question that would be appropriate to ask later on in the history. Although asking the mother about the color of the child's urine is important, the nurse needs to determine whether there is any change in the child's urinary output first.

 CN: Physiological adaptation; CL: Analyze

28. 3. The child with acute poststreptococcal glomerulonephritis experiences a problem with renal function that ultimately affects fluid balance. While intake and output, electrolytes, and vital signs all provide information about fluid status, weight is the best indicator of fluid balance.

 CN: Physiological adaptation; CL: Analyze

29. 2. The most appropriate and effective choice would be ice chips because they help moisten the mouth and lips while keeping fluid intake low. However, ice chips must still be counted as intake with the fluid restriction. Sweet beverages, such as diet cola or lemonade, commonly increase thirst. Tap water effectively relieves thirst but does not help keep fluid intake low.

 CN: Physiological adaptation; CL: Synthesize

30. 1. Generally, school-age children enjoy activities with their peers first, then family members, and lastly younger children. School-age children like to be busy but also to accomplish something. This helps to meet their task of

industry versus inferiority, feeling good about what they are able to accomplish.

CN: Health promotion and maintenance; CL: Create

31. 1. The nurse should assess the child's neurologic status because hypertensive encephalopathy is a major potential complication of the acute phase of glomerulonephritis. Seizure precautions also should be instituted. Hypertensive encephalopathy can result in transient loss of vision, hemiparesis, disorientation, and grand mal seizures. Encouraging the child to drink more water is inappropriate because the child has had a low urine output for 14 hours. Typically, in this situation, fluids would be restricted. Although a low-sodium diet is encouraged, it is not the priority action at this time. Initially, bed rest, not ambulation, is advocated during the acute phase of glomerulonephritis.

CN: Reduction of risk potential; CL: Synthesize

32. 3. Children recovering from glomerulonephritis need to avoid exposure to all types of infections. Glomerulonephritis is caused by group A beta hemolytic streptococcus, a common cause of sore throat. As the child recovers, he or she may be susceptible to a recurrence if exposed to the organism again. During convalescence from glomerulonephritis, fluid and dietary restrictions are no longer indicated because the kidneys are now functioning normally. There is no need for the parents to assess the child's vital signs.

CN: Physiological adaptation; CL: Synthesize

33. 2. The nurse would expect a person with a normal glomerular filtration rate (GFR) to have approximately equal inputs and outputs. Chronic renal failure has five stages. In stage I, the GFR is approximately ≥ 90 mL/min/1.73 m². In stage II, the GFR decreases to approximately 60 to 89 mL/min/1.73 m². The decreased urine output may indicate worsening disease and should be reported. Assessing the client's intake and output is still important, but notifying the provider is the priority. Fluids are restricted based on decreased sodium. Clients are encouraged to drink to thirst. Therefore, there is not enough information to suggest increasing or restricting fluids.

CN: Physiological adaptation; CL: Synthesize

34. 3. APSGN is an immune complex disease. Large antigen-antibody complexes are formed that deposit in the glomerular capillary loops leading to obstruction. APSGN is considered an autoimmune disorder, not an infection. Antibodies do not attack the kidneys in this disorder.

CN: Physiologic adaptation; CL: Analyze

The Client with Nephrotic Syndrome

35. 2,3,5. Adverse effects of steroid therapy include edema of the face and trunk, increased susceptibility to infection, gastric and intestinal mucosal bleeding, sodium and water retention, and hypertension. Steroid therapy can also cause vision problems. Urinary output is decreased due to the retention of sodium. Bleeding gums do not result from steroids.

CN: Pharmacological and parenteral therapies; CL: Create

36. 3. Readings at or above the 95th percentile are considered indicative of hypertension. Here, both the systolic and diastolic readings are at the 95th percentile for a boy who is at the 75th percentile for height. This blood pressure may be a side effect of the medication or part of the disease process and needs to be reported. The charts do not define hypotension. Readings below the 90th percentile are considered normal. Blood pressures at the 90th percentile but below the 95th are considered prehypertension. Blood pressures at the 99th percentile are considered stage II hypertension and are most likely to need antihypertensive medications.

CN: Reduction of risk potential; CL: Analyze

37. 1. The child with nephrotic syndrome would present with hypoalbuminemia due to a decrease of albumin in the bloodstream and to the increase in the glomerular permeability. Nephrotic syndrome is characterized by edema, massive proteinuria, hypoalbuminemia, hypoproteinemia, hyperlipidemia, and altered immunity.

CN: Reduction of risk potential; CL: Evaluate

38. 1. Children with nephrotic syndrome usually require sodium

restriction. Because potato chips and bologna are high in sodium, the mother's statement about finding something else reflects understanding of this need. Although fluid intake is not restricted in children with nephrotic syndrome, 4 L is an excessive amount for a toddler. The typical fluid requirement for a toddler is 115 mL/kg. Surgical intervention and antibiotic therapy are not parts of the treatment plan for nephrotic syndrome.

 CN: Physiological adaptation; CL: Evaluate

39. 4. The best indicator of fluid balance is weight. Therefore, daily weight measurements help determine fluid losses and gains. Although limiting visitors to 2 to 3 hours per day or maintaining strict bed rest would help to ensure that the child gets adequate rest, this is unrelated to the child's fluid balance. In nephrotic syndrome, urine is tested for protein, not specific gravity.

 CN: Physiological adaptation; CL: Synthesize

40. 2. The child's swollen eyes are caused by fluid accumulation. Elevating the head of the bed allows gravity to increase the downward flow of fluids in the body, away from the face. Applying cool compresses or eyedrops, or limiting television, may be comforting but will not relieve the swelling.

 CN: Physiological adaptation; CL: Synthesize

41. 1. Fluid accumulates in the abdomen and interstitial spaces owing to hydrostatic pressure changes. Increased abdominal fluid is evidenced by an increase in abdominal girth. Therefore, decreased abdominal girth is a sign of reduced fluid in the third spaces and tissues. When fluid accumulates in the abdomen and interstitial spaces, the child does not feel hungry and does not eat well. Although increased caloric intake may indicate decreased intestinal edema, it is not the best and most accurate indicator of fluid retention. Increased respiratory rate may be an indication of increasing fluid in the abdomen (ascites) causing pressure on the diaphragm. Heart rate usually stays in the normal range even with excessive fluid volume.

 CN: Physiological adaptation; CL: Evaluate

42. 4. Placing soft cloth between opposing skin surfaces absorbs moisture

and keeps the area dry, thus preventing any further breakdown. The child with nephrotic syndrome and severe edema is usually maintained on bed rest. Therefore, ambulation is not appropriate. Applying lotion or powder to edematous surfaces that touch increases moisture and can lead to maceration, causing further breakdown.

 CN: Basic care and comfort; CL: Synthesize

43. 11.3 mg

$$11.3 \text{ kg} \times 2 \text{ mg} = 22.7 \text{ mg/day}$$

$$22.7 \text{ mg} \div 2 = 11.3 \text{ mg per dose}$$

 CN: Pharmacological and parenteral therapies; CL: Apply

44. 2. A child recovering from nephrotic syndrome should be protected from infection. Therefore, the nurse would teach the parents to keep the child away from others with an infection. Because pain is not associated with this disorder, pain medication typically is not needed. The **HCP** should be notified if urine output decreases, not increases. In children recovering from nephrotic syndrome, there is no reason to administer acetaminophen daily.

 CN: Reduction of risk potential; CL: Synthesize

The Client with Acute or Chronic Renal Failure

45. 3. A client who has had a ruptured appendix may have peritoneal scarring that may alter the effectiveness of treatment. Living a long distance from a medical facility is typically a reason to select peritoneal dialysis. Attending a large school is not a problem, but the school nurse needs to be included as part of the healthcare team. Typically, the treatment schedule can be planned to allow for uninterrupted sleep at night.

 CN: Management of care; CL: Create

46. 3. Until it heals, the catheter exit site is particularly vulnerable to invasion by pathogenic organisms. Therefore, the site must be monitored for signs of infection. An occlusive dressing is not needed because there is no

danger of air being sucked in or out of the peritoneal space. Furthermore, the catheter used is designed with a cuff so that the skin grows around the catheter, sealing off the area. Site care may be done at any time, but the child may experience abdominal discomfort if the peritoneal space is dry during site care. Holding the catheter taut or pulling on it may cause irritation of the skin at the exit site, which could lead to infection.

CN: Safety and infection control; CL: Synthesize

47. 4. With minimal or absent kidney function, the serum phosphate level rises, and the ionized calcium level falls in response. This causes increased secretion of parathyroid hormone, which releases calcium from the bones. Therefore, the intake of foods high in phosphorus is restricted. Because renal failure results in decreased erythropoietin production, an increase in ascorbic acid intake is needed. Because magnesium is minimally affected by renal failure, its intake need not be restricted.

CN: Physiological adaptation; CL: Apply

48. 4. Demonstration of desire to do the dressing changes and manage medications implies compliance with the medical regimen and acceptance of the condition, thereby indicating a positive self-image. Diffuse somatic symptoms could indicate anxiety or problems with coping, with a negative effect on self-concept. Insistence on choosing restricted foods implies that the adolescent has not accepted the diagnosis and is noncompliant, possibly indicating a negative self-concept. Social withdrawal from activities may indicate depression, possibly negatively affecting the self-concept.

CN: Physiological adaptation; CL: Evaluate

49. 2. The child with acute renal failure needs extra calories to reduce tissue catabolism, metabolic acidosis, and uremia. Using a high-fat and high-carbohydrate diet helps to supply the necessary extra calories. If the child is able to tolerate oral foods, concentrated food sources that are high in carbohydrate and fat but low in protein, potassium, and sodium may be provided.

CN: Physiological adaptation; CL: Apply

50. 3. For an adolescent, body image is a major concern. The presence of

an abdominal catheter can greatly affect the client's body image. The adolescent needs opportunities to discuss feelings about altered body image due to the catheter. Adolescents need to be with their peers and to maintain social activities and contacts in order to meet the developmental tasks for this age group. The adolescent client may choose to confide in friends for both psychological health and physical safety. Because peers are most important to adolescents, they will confide in their peers before confiding in family members. Another major developmental need of the adolescent is achieving independence. Relying on the parents would interfere with the adolescent's ability to do so.

 CN: Psychosocial integrity; CL: Create

51. 4. Tissue swelling, pain, redness, and exudate indicate infection. Dialysate leakage is associated with improper catheter function, incomplete healing at the insertion site, or excessive instillation of dialysate. Granulation tissue indicates healing around the exit site, not infection. Increased time for drainage may indicate that the tube is kinked, suggesting an obstruction.

 CN: Reduction of risk potential; CL: Analyze

52. 1. Normally, dialysate drainage return should be clear. With peritonitis, large numbers of bacteria, white blood cells, and fibrin cause the dialysate to appear cloudy. Abdominal distention is unrelated to peritonitis. However, it might suggest an obstruction. Weight gain and shortness of breath are associated with fluid excess, not infection.

 CN: Physiological adaptation; CL: Evaluate

53. 4. With edema, pallor can occur owing to hemodilution as intestinal fluid moves to the vascular space. The child would exhibit pulmonary crackles secondary to pulmonary congestion and edema. Dialysate outflow would decrease, not increase, as the body attempts to conserve fluid. The child's blood pressure would be increased because of excessive fluid volume.

 CN: Physiological adaptation; CL: Analyze

54. 1. Accumulation of hard stool in the bowel can cause the distended intestine to block the holes of the catheter. Consequently, the dialysate cannot flow freely through the catheter. Decreasing the dialysate infusion may make

the dialysis less effective. Altering fluid, electrolyte, and waste product removal can cause fluid and electrolyte imbalance and increased levels of blood urea nitrogen and creatinine. Incorporating the increased times into the dialysis may make the dialysis less effective because fewer cycles can be scheduled. Shoulder pain, which may occur occasionally, can be caused by air in the peritoneal space and diaphragmatic irritation. However, it is unrelated to inflow and drain times.

CN: Physiological adaptation; CL: Synthesize

55. 4. Regulation of the diet is the most effective means, besides dialysis, for reducing renal excretion. Dietary phosphorus is restricted, which reduces the protein load on the kidneys. Clients are also given substances to bind phosphorus in the intestines to prevent absorption. Limited protein in the diet should include foods high in essential amino acids. Foods high in fat and carbohydrate are used to increase caloric intake. Sodium and water may not be restricted because of the continual loss of sodium and water through the dialysate. Iron-rich foods are commonly high in protein.

CN: Physiological adaptation; CL: Evaluate

The Client with Wilms' Tumor

56. 3. When a client receiving chemotherapy develops neutropenia, eating uncooked fruits and vegetables may pose a health risk due to possible bacterial contamination. All other foods are either cooked or pasteurized and would not produce a health risk.

CN: Safety and infection control; CL: Apply

57. 2. The abdomen of the child with Wilms' tumor should not be palpated because of the danger of disseminating tumor cells. Techniques such as measuring the occipitofrontal circumference (which is done in children younger than 18 months of age because the anterior fontanelle closes between 12 and 18 months of age), upright positioning, and measuring chest circumference are not necessarily contraindicated; however, the child with Wilms' tumor should always be handled gently and carefully.

CN: Physiological adaptation; CL: Analyze

58. 1. A stage II tumor is one that extends beyond the kidney but is completely resected. The tumor staging is verified during surgery to maximize treatment protocols. The following criteria for staging are commonly used: *stage I*, tumor is limited to the kidney and completely resected; *stage II*, tumor extends beyond the kidney but is completely resected; *stage III*, residual nonhematogenous tumor is confined to the abdomen; *stage IV*, hematogenous metastasis occurs, with deposits beyond stage III (lung, bone and brain, liver); and *stage V*, bilateral renal involvement is present at diagnosis.

CN: Physiological adaptation; CL: Evaluate

59. 3. The child who has undergone abdominal surgery is usually placed in a semi-Fowler's position to facilitate draining of abdominal contents and promote pulmonary expansion. The modified Trendelenburg position is used for clients in shock. The Sims' position is likely to be uncomfortable for this child because of the large transabdominal incision. The supine position, without the head elevated, puts the child at increased risk for aspiration.

CN: Reduction of risk potential; CL: Synthesize

60. 1. Children who have undergone abdominal surgery are at risk for intestinal obstruction from a dynamic ileus. Indications of intestinal obstruction include abdominal distention, decreased or absent bowel sounds, and vomiting. Later signs of intestinal obstruction include tachycardia, fever, hypotension, increased respirations, shock, and decreased urinary output.

CN: Reduction of risk potential; CL: Analyze

61. 3. Because the child has only one kidney, measures should be recommended to prevent urinary tract infection and injury to the remaining kidney. Severe pain and dependent edema are not associated with surgery for Wilms' tumor. Dietary sodium is not restricted because function in the remaining kidney is not impaired.

CN: Reduction of risk potential; CL: Create

Managing Care, Quality, and Safety of Children with Health Problems of the Urinary System

62. 4. There are many problems with this medication prescription. The abbreviation QOD is ambiguous and open to various interpretations. The abbreviation D/C may be interpreted as “discontinue” or “discharge.” The prescriber should have specifically stated when to start the lower dose because the nurse could reason beginning the medication that day, the next, or even the day after that. The only safe thing to do is call for clarification.

CN: Safety and infection control; CL: Synthesize

63. 3. The charge nurse should assure the parent that it is okay to use CIC and discuss the conversation with the nurse. It is possible that the nurse was unaware of current research findings or unit policies. The charge nurse should also determine if the parent has the supplies and uses a new catheter each time, but the insertion principles would not change. Parents are frequently taught how to do CIC while a child is in the hospital. Therefore, the rationale that it now becomes unsafe, or that sterile technique is needed, is faulty. Switching nurses will not solve the underlying problem.

CN: Management of care; CL: Synthesize

64. 3. Access to a well-constructed e-history will facilitate care if the adolescent becomes ill while at college. Because the client is 18, legally the nurse cannot transfer the records to the school without permission. Also, the adolescent may need to seek treatment in facilities other than the health center. Instructing the adolescent to always carry the nephrologist’s phone number is not bad advice, but compliance may vary and there is no guarantee the provider will be available in all instances. Telling the parent that the son must learn to manage his own disease does not address the parent’s concern.

CN: Management of care; CL: Synthesize

The Child with Neurologic Health Problems

- Answers, Rationales, and Test-Taking Strategies

The Client with Myelomeningocele

1. Parents bring a 10-month-old boy with myelomeningocele and hydrocephalus with a ventriculoperitoneal shunt to the emergency department. His symptoms include vomiting, poor feeding, lethargy, and irritability. What interventions by the nurse are **most** appropriate? Select all that apply.

- ☐ **1.** Weigh the child.
- ☐ **2.** Listen to bowel sounds.
- ☐ **3.** Palpate the anterior fontanelle.
- ☐ **4.** Obtain vital signs.

☐ 5. Assess pitch and quality of the child's cry.

2. When positioning a neonate with an unrepaired myelomeningocele, which position is **most** appropriate?

- ☐ 1. supine with the hips at 90-degree flexion
- ☐ 2. right side-lying position with the knees flexed
- ☐ 3. prone with hips in abduction
- ☐ 4. supine in semi-Fowler's position with chest and abdomen elevated

3. The nurse is teaching the parents of a child with myelomeningocele how to prevent urinary tract infections. What should the care plan include for this child? Select all that apply.

- ☐ 1. Provide meticulous skin care.
- ☐ 2. Use Crede's maneuver to empty the bladder.
- ☐ 3. Encourage frequent emptying of the bladder.
- ☐ 4. Assure adequate fluid intake.
- ☐ 5. Use tight-fitting diapers around the meatus.

4. The nurse reports to the healthcare provider (HCP) signs of increased intracranial pressure in an infant with a myelomeningocele who has which finding?

- ☐ 1. minimal lower extremity movement
- ☐ 2. a high-pitched cry
- ☐ 3. overflow voiding only
- ☐ 4. a fontanelle that bulges with crying

5. When developing the plan of care for an infant diagnosed with myelomeningocele and the parents who have just been informed of the infant's diagnosis, which action should the nurse include as the **priority** when the parents visit the infant for the first time?

- ☐ 1. Emphasize the infant's normal and positive features.
- ☐ 2. Encourage the parents to discuss their fears and concerns.
- ☐ 3. Reinforce the healthcare provider's (HCP's) explanation of the defect.
- ☐ 4. Have the parents feed their infant.

6. The mother of an infant with myelomeningocele asks if her baby is

likely to have any other defects. The nurse responds based on the understanding that myelomeningocele is commonly associated with which disorder?

- ☐ 1. excessive cerebrospinal fluid within the cranial cavity
- ☐ 2. abnormally small head
- ☐ 3. congenital absence of the cranial vault
- ☐ 4. overriding of the cranial sutures

7. The parents of an infant with myelomeningocele ask the nurse about their child's future mental ability. What is the nurse's **best** response?

- ☐ 1. "About one-third have an intellectual disability, but it is too early to tell about your child."
- ☐ 2. "About two-thirds have an intellectual disability significantly retarded, and you will know soon if this will occur."
- ☐ 3. "Your child will probably be of normal intelligence since he demonstrates signs of it now."
- ☐ 4. "You will need to talk with the healthcare provider (HCP) about that, but you can ask later."

8. After placing an infant with myelomeningocele in an Isolette shortly after birth, which indicator should the nurse use as the **best** way to determine the effectiveness of this intervention?

- ☐ 1. The partial pressure of arterial oxygen remains between 94 and 100 mm Hg.
- ☐ 2. The axillary temperature remains between 97°F and 98°F (36.1°C and 36.7°C).
- ☐ 3. The bilirubin level remains stable.
- ☐ 4. Weight increases by about 1 oz (30 g) per day.

9. After surgical repair of a myelomeningocele, which position should the nurse use to prevent musculoskeletal deformity in the infant?

- ☐ 1. Place the feet in flexion.
- ☐ 2. Allow the hips to be abducted.
- ☐ 3. Maintain knees in the neutral position.
- ☐ 4. Place the legs in adduction.

10. When developing the discharge plan for the parents of an infant who has undergone a myelomeningocele repair, what information is **most** important for the nurse to include?

- ☐ 1. a list of available hospital services
- ☐ 2. schedule for daily home health care
- ☐ 3. chaplain referral for psychological support
- ☐ 4. daily care required by the infant

11. Which statement by the parent of an infant with a repaired upper lumbar myelomeningocele indicates that the parent understands the nurse's teaching at the time of discharge?

- ☐ 1. "I can apply a heating pad to his lower back."
- ☐ 2. "I will be sure to keep him away from other children."
- ☐ 3. "I will call the healthcare provider (HCP) if his urine has a funny smell."
- ☐ 4. "I will prop him on pillows to keep him from rolling over."

12. A preschooler with a history of repaired lumbar myelomeningocele is in the emergency department with wheezing and skin rash. Which questions should the nurse ask the parent **first**?

- ☐ 1. "Is your child taking any medications?"
- ☐ 2. "Who brought your child to the emergency department?"
- ☐ 3. "Is your child allergic to bananas or any other food?"
- ☐ 4. "What are you doing to treat your child's skin rash?"

The Client with Hydrocephalus

13. Before placement of a ventriculoperitoneal shunt for hydrocephalus, an infant is irritable, lethargic, and difficult to feed. To maintain the infant's nutritional status, which action would be **most** appropriate?

- ☐ 1. Feed the infant just before doing any procedures.
- ☐ 2. Give the infant small, frequent feedings.
- ☐ 3. Feed the infant in a horizontal position.
- ☐ 4. Give large, less frequent feedings.

14. Which clinical manifestation would lead the nurse to suspect an infant has hydrocephaly? Select all that apply.

- ☐ 1. depressed fontanelle
- ☐ 2. headache
- ☐ 3. vomiting
- ☐ 4. low-pitched cry
- ☐ 5. irritability
- ☐ 6. pupillary changes
- ☐ 7. bulging fontanelle

15. The nurse is providing postoperative care for an infant who had a ventriculoperitoneal shunt placed to correct hydrocephalus. Which clinical finding warrants immediate intervention?

- ☐ 1. abdominal distention
- ☐ 2. lethargy
- ☐ 3. facial edema
- ☐ 4. headache

16. Which action should the nurse take when providing postoperative nursing care to a child after insertion of a ventriculoperitoneal shunt?

- ☐ 1. Administer narcotics for pain control.
- ☐ 2. Check the urine for glucose and protein.
- ☐ 3. Monitoring for increased temperature.
- ☐ 4. Test cerebrospinal fluid leakage for protein.

17. A nurse evaluates discharge teaching as successful when the parents of a school-age child with a ventriculoperitoneal shunt insertion identify which sign as signaling a blocked shunt?

- ☐ 1. decreased urine output with stable intake
- ☐ 2. tense fontanelle and increased head circumference
- ☐ 3. elevated temperature and reddened incisional site
- ☐ 4. irritability and increasing difficulty with eating

The Client with Down Syndrome

18. The mother of a 17-year-old girl with Down syndrome tells the nurse that her daughter recently stated that she has a boyfriend. The mother is concerned that her daughter might become pregnant. Which is the **most** appropriate suggestion made by the nurse?

- ☐ 1. "I understand your concern; you may want to start your daughter on long-acting contraception."
- ☐ 2. "Women with Down syndrome are infertile, so you do not need to worry about her getting pregnant."
- ☐ 3. "I understand your concern; you may want to enroll your daughter in an abstinence program."
- ☐ 4. "I know it may be difficult, but you may want to suggest that your daughter break off the relationship."

19. A nurse is assessing a child who has a mild intellectual disability. The **best** indication of how this child is progressing can be obtained by observing him:

- ☐ 1. at school with his teacher.
- ☐ 2. at home with his family.
- ☐ 3. in the clinic with his mother.
- ☐ 4. playing soccer with his friends.

20. After talking with the parents of a child with Down syndrome, the nurse should help the parents establish which goal?

- ☐ 1. Encourage self-care skills in the child.
- ☐ 2. Teach the child something new each day.
- ☐ 3. Encourage more lenient behavior limits for the child.
- ☐ 4. Achieve age-appropriate social skills.

21. The nurse discusses with the parents how best to raise the IQ of their child with Down syndrome. Which intervention would be **most** appropriate?

- ☐ 1. Serve hearty, nutritious meals.
- ☐ 2. Give vasodilator medications as prescribed.
- ☐ 3. Let the child play with more able children.
- ☐ 4. Provide stimulating, nonthreatening life experiences.

22. When developing a teaching plan for the parents of a child with Down

syndrome, the nurse focuses on activities to increase which factor for the parents?

- ☐ 1. affection for their child
- ☐ 2. responsibility for their child's welfare
- ☐ 3. understanding of their child's disability
- ☐ 4. confidence in their ability to care for their child

The Client with a Seizure Disorder

23. What should be part of the nurse's teaching plan for a child with epilepsy being discharged on a regimen of phenytoin?

- ☐ 1. Drink plenty of fluids.
- ☐ 2. Brush teeth after each meal.
- ☐ 3. Have someone be with the child during waking hours.
- ☐ 4. Report signs of infection.

24. After the nurse instructs a group of schoolteachers about seizures, the teachers role-play a scenario involving a child experiencing a generalized tonic-clonic seizure. Which action, when performed **first**, indicates that the nurse's teaching has been successful?

- ☐ 1. Ask the other children what happened before the seizure.
- ☐ 2. Move the child to the nurse's office for privacy.
- ☐ 3. Remove any nearby objects that could harm the child.
- ☐ 4. Place a padded tongue blade between the child's teeth.

25. A nurse is developing a plan of care with the parents of a 6-year-old girl diagnosed with a seizure disorder. To promote growth and development, the nurse should instruct the parents that:

- ☐ 1. the child will need activity limitation and will be unable to perform as well as her peers.
- ☐ 2. there is potential for a learning disability and the child may need tutoring to reach her grade level.
- ☐ 3. the child will likely have normal intelligence and be able to attend regular school.
- ☐ 4. there will be problems associated with social stigma and parents should

consider home schooling.

26. The parents of a child with occasional generalized seizures want to send the child to summer camp. The parents contact the nurse for advice on planning for the camping experience. Which type of activity should the nurse and family decide the child should avoid?

- ☐ 1. rock climbing
- ☐ 2. hiking
- ☐ 3. swimming
- ☐ 4. tennis

27. Which statement obtained from the nursing history of a toddler should alert the nurse to suspect that the child has had a febrile seizure?

- ☐ 1. The child has had a low-grade fever for several weeks.
- ☐ 2. The family history is negative for convulsions.
- ☐ 3. The seizure resulted in respiratory arrest.
- ☐ 4. The seizure occurred when the child had a respiratory infection.

28. After teaching the parents of a child with febrile seizures about methods to lower temperature other than using medication, which statement indicates successful teaching?

- ☐ 1. "We will add extra blankets when he says he is cold."
- ☐ 2. "We will wrap him in a blanket if he starts shivering."
- ☐ 3. "We will make the bath water cold enough to make him shiver."
- ☐ 4. "We will use a solution of half alcohol and half water when sponging him."

29. An adolescent girl with a seizure disorder controlled with phenytoin and carbamazepine asks the nurse about getting married and having children. Which response by the nurse would be **most** appropriate?

- ☐ 1. "You probably should not consider having children until your seizures are cured."
- ☐ 2. "Your children will not necessarily have an increased risk of seizure disorder."
- ☐ 3. "When you decide to have children, talk to the healthcare provider (HCP) about changing your medication."

- ☐ 4. “Women who have seizure disorders commonly have a difficult time conceiving.”

30. When teaching an adolescent with a seizure disorder who is receiving valproic acid, which sign or symptom should the nurse instruct the client **immediately** to report to the healthcare provider (HCP)?

- ☐ 1. diarrhea
- ☐ 2. loss of appetite
- ☐ 3. jaundice
- ☐ 4. sore throat

The Client with Meningitis

31. A 3-month-old infant with meningococcal meningitis has just been admitted to the pediatric unit. Which nursing intervention has the **highest priority**?

- ☐ 1. instituting droplet precautions
- ☐ 2. administering acetaminophen
- ☐ 3. obtaining history information from the parents
- ☐ 4. orienting the parents to the pediatric unit

32. During the acute stage of meningitis, a 3-year-old child is restless and irritable. Which intervention would be **most** appropriate to institute?

- ☐ 1. limiting conversation with the child
- ☐ 2. keeping extraneous noise to a minimum
- ☐ 3. allowing the child to play in the bathtub
- ☐ 4. performing treatments quickly

33. Which sign should lead the nurse to suspect that a child with meningitis has developed disseminated intravascular coagulation?

- ☐ 1. hemorrhagic skin rash
- ☐ 2. edema
- ☐ 3. cyanosis
- ☐ 4. dyspnea on exertion

34. When interviewing the parents of a 2-year-old child, a history of which

illnesses should lead the nurse to suspect pneumococcal meningitis?

- ☐ 1. bladder infection
- ☐ 2. middle ear infection
- ☐ 3. fractured clavicle
- ☐ 4. septic arthritis

35. A preschooler with pneumococcal meningitis is receiving intravenous antibiotic therapy. When discontinuing the intravenous therapy, the nurse allows the child to apply a dressing to the area where the catheter is removed. The nurse's rationale for doing so is based on the interpretation that a child in this age group has a need to accomplish which goal?

- ☐ 1. trust those caring for her
- ☐ 2. find diversional activities
- ☐ 3. protect the image of an intact body
- ☐ 4. relieve the anxiety of separation from home

36. A child with meningitis is to receive 1,000 mL of dextrose 5% in normal saline over 12 hours. At what rate in milliliters per hour should the nurse set the pump? Round your answer to the nearest whole number.

_____ mL/h.

37. Nursing care management of the child with bacterial meningitis includes which interventions? Select all that apply.

- ☐ 1. administration of IV antibiotics
- ☐ 2. intravenous fluids at 1½ times maintenance
- ☐ 3. decreasing environmental stimuli
- ☐ 4. neurologic checks every 4 hours
- ☐ 5. administration of IV anticonvulsants

38. The nurse is monitoring an infant with meningitis for signs of increased intracranial pressure (ICP). The nurse should assess the infant for which signs or symptoms? Select all that apply.

- ☐ 1. irritability
- ☐ 2. headache
- ☐ 3. mood swings

- ☐ 4. bulging fontanelle
- ☐ 5. emesis

39. A hospitalized preschooler with meningitis who is to be discharged becomes angry when the discharge is delayed. Which play activity would be **most** appropriate at this time?

- ☐ 1. reading the child a story
- ☐ 2. painting with watercolors
- ☐ 3. pounding on a pegboard
- ☐ 4. stacking a tower of blocks

The Client with Near-Drowning

40. The nurse is admitting a toddler with the diagnosis of near-drowning in a neighbor's heated swimming pool to the emergency department. The nurse should assess the child for:

- ☐ 1. hypothermia.
- ☐ 2. hypoxia.
- ☐ 3. fluid aspiration.
- ☐ 4. cutaneous capillary paralysis.

41. The nurse is caring for a lethargic 4-year-old who is a victim of a near-drowning accident. The nurse should **first**:

- ☐ 1. administer oxygen.
- ☐ 2. institute rewarming.
- ☐ 3. prepare for intubation.
- ☐ 4. start an intravenous infusion.

42. The parents of a child tell the nurse that they feel guilty because their child almost drowned. Which remark by the nurse would be **most** - appropriate?

- ☐ 1. "I can understand why you feel guilty, but these things happen."
- ☐ 2. "Tell me a little bit more about your feelings of guilt."
- ☐ 3. "You should not have taken your eyes off of your child."
- ☐ 4. "You should focus on the fact that your child will be all right."

The Client with Guillain-Barré Syndrome (Infectious Polyneuritis)

43. Which assessment would be **most** important for the nurse to make initially in a school-age child being seen in the clinic who has a sore throat, muscle tenderness, arms feeling weak, and generally is not feeling well?

- ☐ 1. difficulty swallowing
- ☐ 2. diet intake for the last 24 hours
- ☐ 3. exposure to illnesses
- ☐ 4. difficulty urinating

44. Which action should be the **priority** when caring for a school-age child admitted to the pediatric unit with the diagnosis of Guillain-Barré - syndrome?

- ☐ 1. Assess the child's ability to follow simple commands.
- ☐ 2. Evaluate the child's bilateral muscle strength.
- ☐ 3. Make a game of the range-of-motion exercises.
- ☐ 4. Provide the child with a diversional activity.

45. The nurse asks a school-age child with Guillain-Barré syndrome to cough and also assesses the child's speech for decreased volume and clarity. The underlying rationale for these assessments is to determine which finding?

- ☐ 1. inflammation of the larynx and epiglottis
- ☐ 2. increased intracranial pressure
- ☐ 3. involvement of facial and cranial nerves
- ☐ 4. regression to an earlier developmental phase

46. Assessment of a school-age child with Guillain-Barré syndrome reveals absent gag and cough reflexes. Which problem should receive the **highest priority** during the acute phase?

- ☐ 1. risk for infection due to altered immune system
- ☐ 2. ineffective breathing pattern related to neuromuscular impairment
- ☐ 3. impaired swallowing related to neuromuscular impairment
- ☐ 4. fluid volume deficits related to total urinary incontinence

47. A 9-year-old child with Guillain-Barré syndrome requires mechanical

ventilation. Which action should the nurse take?

- ☐ 1. Maintain the child in a supine position to prevent unnecessary nerve stimulation.
- ☐ 2. Transfer the child to a bedside chair three times a day to prevent postural hypotension.
- ☐ 3. Engage the child in vigorous passive range-of-motion exercises to prevent loss of muscle function.
- ☐ 4. Turn the child slowly and gently from side to side to prevent respiratory complications.

48. The parent brings a child to the clinic after discharge from the hospital for Guillain-Barré syndrome. Which statement by the parent indicates that the discharge plan is being followed?

- ☐ 1. “She and her sister argue all day.”
- ☐ 2. “I have to bribe her to get her to do her exercises.”
- ☐ 3. “I take her to the pool where she can exercise with other children.”
- ☐ 4. “She has missed a few of her therapy sessions because she often sleeps.”

The Client with a Head Injury

49. A 12-year-old child has had a traumatic head injury from playing in a football game. He is admitted to the emergency department and transferred to the pediatric intensive care unit. He has an IV of dextrose 5% in water at 21 mL/h and nasal oxygen at 2 L/min. The nurse is assessing the child at the beginning of the shift (2300 hours) and reviews the Glasgow Coma Scale flow sheet below. The nurse notes that the child responds to pain, is making incomprehensible sounds, and has abnormal flexion of the limbs. What should the nurse do **first**?

Flow Sheet

Glasgow Coma Scale

Test	Score	Client's response
Eye Opening		
Spontaneously	4	Opens eyes spontaneously
To Speech	3	Opens eyes to verbal command
To Pain	2	Opens eyes to painful stimulus
None	1	Doesn't open eyes in response to stimulus
Motor Response		
Obeys	6	Reacts to verbal command
Localizes	5	Identifies localized pain
Withdraws	4	Flexes and withdraws from painful stimulus
Abnormal Flexion	3	Assumes a decorticate position
Abnormal Extension	2	Assumes a decerebrate position
None	1	No response; lies flaccid
Verbal Response		
Oriented	5	Is oriented and converses
Confused	4	Is disoriented and confused
Inappropriate Words	3	Replies randomly with incorrect words
Incomprehensible	2	Moans or screams
None	1	No response
Date	Time	Progress Notes
11/13	1700	GCS = 13
11/13	1800	GCS = 12
11/13	1900	GCS = 13
11/13	2000	GCS = 11
11/13	2100	GCS = 10
11/13	2200	GCS = 9

- ☐ 1. Notify the healthcare provider (HCP).
- ☐ 2. Lower the head of the bed.
- ☐ 3. Increase the rate of nasal oxygen.
- ☐ 4. Increase the rate of the IV infusion.

50. A 10-year-old with a severe head injury is unconscious and has coarse breath sounds, a temperature of 39°C (102.2°F), a heart rate of 70 bpm, a blood pressure of 130/60 mm Hg, and an intracranial pressure (ICP) of 36 mm Hg. Which action should the nurse perform **first**?

- ☐ 1. Administer prescribed IV mannitol.
- ☐ 2. Suction the child.
- ☐ 3. Encourage the parent to talk to the child.
- ☐ 4. Administer prescribed rectal acetaminophen.

51. The nurse is inserting a nasogastric (NG) tube in a child admitted with head trauma. The nurse should explain to the parents that the NG tube will be used for what purpose?

- ☐ 1. Administer medications.
- ☐ 2. Decompress the stomach.
- ☐ 3. Obtain gastric specimens for analysis.
- ☐ 4. Provide adequate nutrition.

52. A nasogastric tube is prescribed to be inserted for a child with severe head trauma. Diagnostic testing reveals that the child has a basilar skull fracture. What should the nurse do **next**?

- ☐ 1. Ask for the prescription to be changed to an oral gastric tube.
- ☐ 2. Attempt to place the tube into the duodenum.
- ☐ 3. Test the gastric aspirate for blood.
- ☐ 4. Use extra lubrication when inserting the nasogastric tube.

53. The parents of a child in a coma with a serious head injury ask the nurse if the child is going to be all right. Which response by the nurse would be **most** appropriate?

- ☐ 1. "Children usually do not do very well after head injuries like this."
- ☐ 2. "Children usually recover rapidly from head injuries."

- ☐ 3. “It is hard to tell this early, but we will keep you informed of the progress.”
- ☐ 4. “That is something you will have to talk to the healthcare provider (HCP) about.”

54. A parent of a child with a moderate head injury asks the nurse, “How will you know if my child is getting worse?” The nurse should tell the parents that **best** indicator of the child’s brain function is:

- ☐ 1. the vital signs.
- ☐ 2. level of consciousness.
- ☐ 3. reactions of the pupils.
- ☐ 4. motor strength.

55. When developing the plan of care for a child who is unconscious after a serious head injury, in which position should the nurse expect to place the child?

- ☐ 1. prone with hips and knees slightly elevated
- ☐ 2. lying on the side, with the head of the bed elevated
- ☐ 3. lying on the back, in the Trendelenburg position
- ☐ 4. in the semi-Fowler’s position, with arms at the side

56. The healthcare provider (HCP) has prescribed intravenous mannitol for a child with a head injury. The **best** indicator that the drug has been effective is:

- ☐ 1. increased urine output.
- ☐ 2. improved level of consciousness.
- ☐ 3. decreased intracranial pressure.
- ☐ 4. decreased edema.

57. The nurse assigned to telephone triage returns the call of a parent whose teenager experienced a hard tackle last night. The parent reports, “He seemed dazed after it happened, and the coach had him sit out the rest of the game, but he is fine now.” What is the **most** appropriate instruction for the nurse to give?

- ☐ 1. “Take him immediately to the emergency department.”
- ☐ 2. “He cannot return to play until he has been evaluated by a healthcare

provider (HCP).”

- ☐ 3. “If he seems fine now and had no other symptom, it probably was not a concussion.”
- ☐ 4. “Watch him closely, and call us back if you see any changes.”

58. A history of which factors will complicate the recovery from a concussion? Select all that apply.

- ☐ 1. asthma
- ☐ 2. attention deficit hyperactivity disorder (ADHD)
- ☐ 3. depression
- ☐ 4. migraines
- ☐ 5. obesity
- ☐ 6. previous concussion

59. A 3-year-old is recovering from a concussion. The persistence of which finding would the nurse consider as being a normal finding for a 3-year-old?

- ☐ 1. lack interest in favorite toys
- ☐ 2. change in eating habits
- ☐ 3. inability to hop
- ☐ 4. increased temper tantrums

60. The nurse teaches an adolescent about returning to school after a concussion. Which statement by the client reflects the need for more - teaching?

- ☐ 1. “I should limit my activities that require concentration.”
- ☐ 2. “I must slowly return to my previous activity level as my symptoms improve.”
- ☐ 3. “My symptoms may reemerge with exertion.”
- ☐ 4. “Time is the most important factor in my recovery.”

The Client with a Brain Tumor

61. A child with a brain tumor is less responsive to verbal commands than he was when the nurse assessed the client the previous hour. What should the nurse do **next**?

- ☐ 1. Raise the head of the bed.
- ☐ 2. Notify the healthcare provider (HCP).
- ☐ 3. Administer an analgesic.
- ☐ 4. Obtain an oximeter reading.

62. The nurse is caring for a 3-year-old client with a neuroblastoma who has been receiving chemotherapy for the last 4 weeks. His lab results indicate an Hgb of 12.5 g/dL (125 g/L), an HCT of 36.8% (0.37), a WBC of 2,000 mm³ (2×10^9 /L), and a platelet count of 150,000 μ L (150×10^9 /L). Based on the child's lab values, what is the **highest priority** nursing intervention?

- ☐ 1. Encourage meticulous handwashing by the client and visitors.
- ☐ 2. Prepare to give the child a transfusion of platelets.
- ☐ 3. Encourage mouth care with a soft toothbrush.
- ☐ 4. Prepare to give the child a transfusion of packed red blood cells.

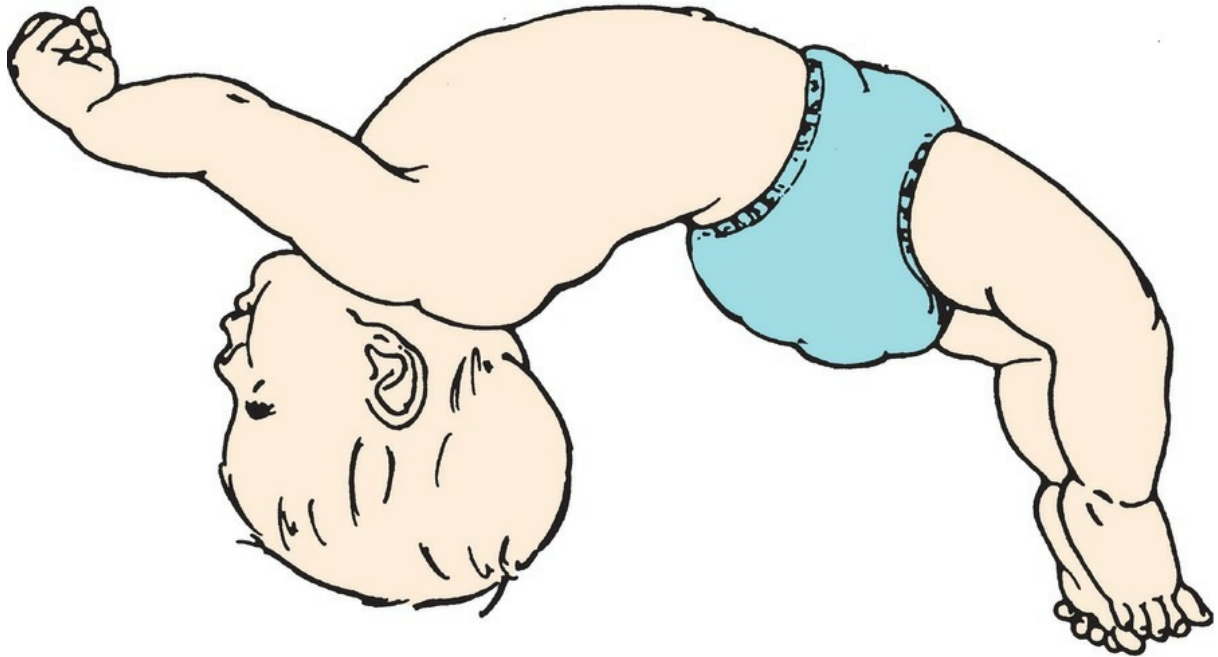

63. A 13-year-old child has seen the school nurse several times with headache, vomiting, and difficulty walking. When calling the adolescent's mother about these symptoms, what should the nurse suggest the mother do **first**?

- ☐ 1. Schedule an appointment with the eye healthcare provider (HCP).
- ☐ 2. Begin psychological counseling for her adolescent.
- ☐ 3. Make an appointment with the adolescent's healthcare provider (HCP).
- ☐ 4. Meet with the adolescent's teachers to determine academic progress.

64. A school-age child is admitted to the hospital with the diagnosis of probable infratentorial brain tumor. During the child's admission to the pediatric unit, which action should the nurse anticipate taking **first**?

- ☐ 1. Eliminate the child's anxiety.
- ☐ 2. Implement seizure precautions.
- ☐ 3. Introduce the child to other clients of the same age.
- ☐ 4. Prepare the child and parents for diagnostic procedures.

65. The nurse is giving care to an infant with a brain tumor. The nurse observes the infant arches the back (see figure). The nurse should:

- ☐ 1. notify the healthcare provider (HCP).
- ☐ 2. stroke the back to release the arching.
- ☐ 3. pad the side rails of the crib.
- ☐ 4. place the child prone.

66. The nurse is assessing a child diagnosed with a brain tumor. Which signs and symptoms should the nurse expect the child to demonstrate? Select all that apply.

- ☐ 1. head tilt
- ☐ 2. vomiting
- ☐ 3. polydipsia
- ☐ 4. lethargy
- ☐ 5. increased appetite
- ☐ 6. increased pulse

67. After a child undergoes a craniotomy for an infratentorial brain tumor, the nurse should place the child in which position to prevent undue strain on the sutures?

- ☐ 1. prone
- ☐ 2. semi-Fowler's
- ☐ 3. side-lying

☐ 4. Trendelenburg

68. A child who was intubated after a craniotomy now shows signs of decreased level of consciousness. The healthcare provider (HCP) prescribes manual hyperventilation to keep the PaCO₂ between 25 and 29 mm Hg and the PaO₂ between 80 and 100 mm Hg. The nurse interprets this prescription based on the understanding that this action will accomplish which goal?

- ☐ 1. decrease intracranial pressure
- ☐ 2. ensure a patent airway
- ☐ 3. lower the arousal level
- ☐ 4. produce hypoxia

69. Which action should the nurse do **first** when noting clear drainage on the child's dressing and bed linen after a craniotomy for a brain tumor?

- ☐ 1. Change the dressing.
- ☐ 2. Elevate the head of the bed.
- ☐ 3. Test the fluid for glucose.
- ☐ 4. Notify the healthcare provider (HCP).

70. An 8-year-old child does well after infratentorial tumor removal and is transferred back to the pediatric unit. Although she had been told about having her head shaved for surgery, she is very upset. After exploring the child's feelings, which action should the nurse take?

- ☐ 1. Ask the child if she would like to wear a hat.
- ☐ 2. Reassure the child that her hair will grow back.
- ☐ 3. Explain to the child's parents that her reaction is normal.
- ☐ 4. Suggest that the parents buy the child a wig as a surprise.

71. Which statement made by the parent of a school-age child who has had a craniotomy for a brain tumor would warrant further exploration by the nurse?

- ☐ 1. "After this, I will never let her out of my sight again."
- ☐ 2. "I hope that she will be able to go back to school soon."
- ☐ 3. "I wonder how long it will be before she can ride her bike."
- ☐ 4. "Her best friend is eager to see her; I hope she will not be upset."

The Client with a Spinal Cord Injury

72. A nurse, who witnesses an accident involving an adolescent being thrown from a motorcycle, stops to help. The adolescent reports that he is now unable to move his legs. While waiting for the emergency medical service to arrive, what should the nurse do?

- ☐ **1.** Flex the adolescent's knees to relieve stress on his back.
- ☐ **2.** Leave the adolescent as he is, staying close by.
- ☐ **3.** Remove the adolescent's helmet as soon as possible.
- ☐ **4.** Assess the adolescent for abdominal trauma.

73. An adolescent sustains a T3 spinal cord injury. After insertion of an intravenous line, a nasogastric tube, and an indwelling urinary (Foley) catheter, the adolescent is admitted to the intensive care unit. What should the nurse do **next** when assessment reveals that the adolescent's feet and legs are cool to the touch?

- ☐ **1.** Cover the adolescent's legs with blankets.
- ☐ **2.** Report this finding to the healthcare provider (HCP) immediately.
- ☐ **3.** Reposition the adolescent's legs.
- ☐ **4.** Lay the adolescent flat to aid circulation.

74. During assessment of an adolescent who has sustained a recent thoracic spinal injury, the nurse auscultates the adolescent's abdomen. The nurse explains to the parents that this is necessary because clients with spinal cord injury often develop which problem?

- ☐ **1.** abdominal cramping
- ☐ **2.** hyperactive bowel sounds
- ☐ **3.** paralytic ileus
- ☐ **4.** profuse diarrhea

75. Which finding should lead the nurse to decide that spinal shock was resolving in the adolescent with a spinal cord injury?

- ☐ **1.** atonic urinary bladder
- ☐ **2.** flaccid paralysis
- ☐ **3.** hyperactive reflexes

- ☐ 4. widened pulse pressure

76. A school-age boy with a spinal cord injury is moved to the rehabilitation unit. The nurse notes that the child tends to refuse to cooperate in care and to be hostile. The nurse interprets this behavior as indicative of which response?

- ☐ 1. a stage of grief reaction
- ☐ 2. a phase of rebellion
- ☐ 3. a reaction to sensory overload
- ☐ 4. a response to too much attention

77. Two months after an adolescent's thoracic spinal cord injury, he has a pounding headache. The nurse notes that the client's arms and face are flushed and he is diaphoretic. What should the nurse do **next**?

- ☐ 1. Check the patency of the urinary catheter.
- ☐ 2. Lower the adolescent's head below his knees.
- ☐ 3. Place the adolescent flat on his back.
- ☐ 4. Prepare to administer epinephrine subcutaneously.

Managing Care, Quality, and Safety of Children with Neurologic Health Problems

78. The nurse is admitting a child who has been diagnosed with bacterial meningitis to the pediatric unit. The nurse should implement which type of isolation?

- ☐ 1. standard or routine precautions
- ☐ 2. contact precautions
- ☐ 3. airborne precautions
- ☐ 4. droplet precautions

79. The nurse manager on a pediatric floor is updating safety recommendations for the unit. Which strategy would help reduce pediatric medication errors? Select all that apply.

- ☐ 1. Eliminate the pediatric satellite pharmacy.
- ☐ 2. Increase the number of steps in the medication administration procedure.

- ☐ 3. Avoid using parenteral syringes when administering liquid oral medications.
- ☐ 4. Limit the size of IV fluid bags that can be hung on small children.
- ☐ 5. Reduce the available concentrations or dose strengths of high-alert medications to the minimum.

80. The healthcare provider (HCP) prescribes carbamazepine extended release for a client with a cerebral palsy who also has a seizure disorder. The client has a gastrostomy feeding tube, and carbamazepine is on the hospital's "no crush" list. In order to administer the medication, the nurse should:

- ☐ 1. cut the medication into four pieces that can be placed in the feeding tube.
- ☐ 2. dissolve the medication in 30 mL of juice.
- ☐ 3. ask the pharmacist for an oral suspension.
- ☐ 4. contact the HCP to change the prescription.

81. When making rounds on the pediatric neurology unit, the nurse manager notes that when giving IV medications many of the staff nurses are disconnecting the flush syringe first and then clamping the intermittent infusion device. The nurse is concerned that the nurses do not understand the benefits of positive pressure technique and turbulence flow flush in preventing clots. After discussing the problem with the staff educator, which intervention would be the **most** effective way to improve the nursing practice?

- ☐ 1. Create a poster presentation on the topic with a required posttest.
- ☐ 2. Send a group e-mail discussing the importance of clamping the device first.
- ☐ 3. Ask each nurse if he or she is aware that his or her practice is not current.
- ☐ 4. Post an evidence-based article on the unit.

82. The emergency department nurse has admitted an infant with bulging fontanelles, setting sun eyes, and lethargy. Which diagnostic procedure would be **contraindicated** in this infant?

- ☐ 1. lumbar puncture
- ☐ 2. magnetic resonance imaging

- ☐ 3. arterial blood draw
- ☐ 4. computerized tomography scan

83. A 7-year-old with a history of tonic-clonic seizures has been actively seizing for 10 minutes. The child weighs 22 kg and currently has an IV of D5 NS + 20 mEq KCl/L running at 60 mL/h. The vital signs are temperature 100.4°F (38°C), heart rate 120 bpm, respiratory rate 28 breaths/min, and oxygen saturation 92%. Using the SBAR (Situation-Background-Assessment-Recommendation) technique for communication, the nurse calls the healthcare provider (HCP) with the recommendation for:

- ☐ 1. rectal diazepam.
- ☐ 2. IV lorazepam.
- ☐ 3. rectal acetaminophen.
- ☐ 4. IV fosphenytoin.

Answers, Rationales, and Test-Taking Strategies

*The answers and the rationales for each question follow below, along with keys (🔑) to the client need (CN) and cognitive level (CL) for each question. In addition, you will also see a glossary icon (📖) highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 12–23 and pages 35–36 in Part 1 of this book.*

The Client with Myelomeningocele

1. 1,2,4,5. Common shunt complications are obstruction, infection, and disconnection of the tubing. The signs presented by the child indicate increased intracranial pressure from a shunt malfunction, which could be caused by an infection, such as peritonitis or meningitis. By listening to bowel sounds, the nurse will note if peritonitis might be a possibility. Intracranial pressure manifests as abulging or taut anterior fontanel, but the

posterior fontanel is typically closed. Obtaining vital signs would assess for signs of infection, such as elevated temperature or, possibly, Cushing's triad (elevated blood pressure, slow pulse, and depressed respirations). A high-pitched cry is a sign of increased intracranial pressure. Weighing the child, while it would not help identify the cause of the problem, would help determine the severity of the dehydration from vomiting.

CN: Physiological adaptation; CL: Synthesize

2. 3. Before surgery, the infant is kept flat in the prone position to decrease tension on the sac. This allows for optimal positioning of the hips, knees, and feet because orthopedic problems are common. The supine position is unacceptable because it causes pressure on the defect. Flexing the knees when side-lying will increase tension on the sac, as will placing the infant in semi-Fowler's position, even though the chest and abdomen are elevated.

CN: Physiological adaptation; CL: Synthesize

3. 2,3,4. Prevention of urinary tract infections includes adequate fluid intake, urine acidification, and frequent emptying of the bladder, with the use of Crede's maneuver if needed. While the nurse should keep the skin clean and dry, this will not prevent urinary tract infections. Keeping urine close to the meatus with a tight-fitting diaper would increase the risk for infection.

CN: Reduction of risk potential; CL: Create

4. 2. A Chiari malformation obstructs the flow of cerebral spinal fluid resulting in hydrocephalus. This is a common problem in infants with myelomeningocele and will require surgical intervention with a shunt. A high-pitched cry is one sign of increased intracranial pressure that may indicate the presence of a Chiari malformation and requires further evaluation. Minimal movement of the lower extremities is an expected finding associated with spinal cord damage. Overflow voiding comes from a neurogenic bladder, not increased intracranial pressure. It is normal for the fontanelle to bulge with crying.

CN: Physiological adaptation; CL: Analyze

5. 1. The parents should see the neonate as soon as possible, because the longer they must wait to see the neonate, the more anxiety they will feel.

Because the parents are acutely aware of the deficit, the nurse should emphasize the neonate's normal and positive features during the visit. All parents, but especially those with a child who has a disability or defect, need to hear positive comments and comments that reflect how the infant is normal. Although the parents need to discuss their fears and concerns, the priority on the first visit is to emphasize the neonate's normal and positive features. Reinforcing the HCP's  explanation of the defect may be necessary later. Reinforcing the explanation at this initial visit emphasizes the defect, not the child. The parents should spend time with or care for the neonate after birth because parent-infant contact is necessary for attachment. The parents cannot feed the neonate before the defect is repaired because the repair typically occurs within 24 hours. The infant will be prone in an Isolette or warmed and watched closely. However, the parents can fondle and stroke the neonate.

CN: Psychosocial integrity; CL: Synthesize

6. 1. Excessive cerebrospinal fluid in the cranial cavity, called *hydrocephalus*, is the most common anomaly associated with myelomeningocele. Microcephaly, an abnormally small head, is associated with maternal exposure to rubella or cytomegalovirus. Anencephaly, a congenital absence of the cranial vault, is a different type of neural tube defect. Overriding of the sutures, possibly a normal finding after a vaginal birth, is not associated with myelomeningocele.

CN: Physiological adaptation; CL: Apply

7. 1. Approximately one-third of infants diagnosed with myelomeningocele have an intellectual disability, but the degree of disability is variable and it is difficult to predict intellectual functioning in neonates. The parents are asking for an answer now and should not be told to talk with the HCP  later.

CN: Physiological adaptation; CL: Synthesize

8. 2. The nurse places the neonate with myelomeningocele in an Isolette shortly after birth to help to maintain the infant's temperature. Because of the defect, the neonate cannot be bundled in blankets. Therefore, it may be difficult to prevent cold stress. The Isolette can be maintained at higher than

room temperature, helping to maintain the temperature of a neonate who cannot be dressed or bundled. Body temperature readings, not arterial oxygen levels, are the best indicator. Typically, an infant loses 5% to 10% of body weight before beginning to regain the weight.

CN: Reduction of risk potential; CL: Analyze

9. 2. Because of the potential for hip dislocation, the neonate's legs should be slightly abducted, hips maintained in slight to moderate abduction, and feet maintained in a neutral position. The infant's knees are flexed to help maintain the hips in abduction.

CN: Reduction of risk potential; CL: Synthesize

10. 4. The most important aspect of the discharge plan is to ensure that the parents understand what the daily care of their infant involves and to provide teaching related to carrying out this daily care. In addition to the routine care required by the infant, care also may include physical therapy to the lower extremities. Providing a list of available hospital services may be helpful to the parents, but it is not the most important aspect to include in the discharge plan. Usually, home health care is not needed because the parents are able to care for their child. A referral for counseling is initiated whenever the need arises, not just at discharge.

CN: Reduction of risk potential; CL: Synthesize

11. 3. Children with a myelomeningocele are prone to urinary tract infections (UTI), and foul-smelling urine is one symptom of a UTI. Because of the level of defect, the child may be insensitive to pressure or heat. Using a heating pad may lead to thermal injury because the child may not be able to sense if the pad is too hot. Keeping the child away from other children is unnecessary and can retard social development. Using pillows as props increases the risk of sudden infant death syndrome.

CN: Safety and infection control; CL: Evaluate

12. 3. Children with myelomeningocele are at high risk for development of latex allergy because of repeated exposure to latex products during surgery and bladder catheterizations. Cross-reactions to food items such as bananas, kiwi, chestnuts, and avocados also occur. These allergic reactions vary in

severity ranging from mild (such as sneezing) to severe anaphylaxis. While the child could have allergies to medications that caused the wheezing, latex and food allergies are more common. Asking about the skin rash is not a priority when a child is wheezing. Who brought the child to the emergency department is irrelevant at this time.

 CN: Reduction of risk potential; CL: Analyze

The Client with Hydrocephalus

13. 2. An infant with hydrocephalus is difficult to feed because of poor sucking, lethargy, and vomiting, which are associated with increased intracranial pressure. Small, frequent feedings given at times when the infant is relaxed and calm are tolerated best. Feeding an infant before any procedure is inappropriate because the stress of the procedure may lead to vomiting. Ideally, the infant should be held in a slightly vertical position when feeding to prevent backflow of formula into the eustachian tubes and subsequent development of ear infections. Giving large, less frequent feedings allows for rest but typically results in more vomiting.

 CN: Basic care and comfort; CL: Synthesize

14. 3,5,6. Hydrocephaly is a block in the flow of cerebral spinal fluid. Hydrocephaly results in increased intracranial pressure (ICP). Vomiting, irritability, bulging fontanelle, and pupillary changes are all signs of increased intracranial pressure in an infant. A depressed fontanelle could be an indication of dehydration, not increased intracranial pressure. A headache may be present in an infant with increased ICP; however, the infant has no way of communicating this to the nurse or parent. A headache is an indication of increased ICP in a verbal child. A high-pitched cry is indicative of infants with increased intracranial pressure.

 CN: Physiological adaptation; CL: Analyze

15. 1. Abdominal distension in a pediatric client with a ventriculoperitoneal shunt can be an indication of peritonitis and requires intervention. Lethargy may be present for several days following surgery for a ventriculoperitoneal shunt. Facial and eye edema is common during the postoperative period and can be reduced by utilizing a cold compress to the

eyes. Infants commonly have pain in the postoperative period that should be treated with analgesics; however, infants cannot convey that they specifically have a headache.

CN: Management of care; CL: Synthesize

16. 3. Monitoring the temperature allows the nurse to assess for infection, the most common and the most hazardous postoperative complication after ventriculoperitoneal shunt placement. Typically, pain after insertion of a ventriculoperitoneal shunt is mild, requiring the use of mild analgesics. Usually, narcotics are not administered because they alter the level of consciousness, making assessment of cerebral function difficult. Neither proteinuria nor glycosuria is associated with shunt placement. Cerebrospinal fluid leakage commonly occurs with head injury. It is not usually associated with shunt placement.

CN: Reduction of risk potential; CL: Synthesize

17. 4. In a school-age child, irritability, lethargy, vomiting, difficulty with eating, and decreased level of consciousness are signs of increased intracranial pressure caused by a blocked shunt. Decreased urine output with stable fluid intake indicates fluid loss from a source other than the kidneys. A tense fontanelle and increased head circumference would be signs of a blocked shunt in an infant. Elevated temperature and redness around incisions might suggest an infection.

CN: Reduction of risk potential; CL: Evaluate

The Client with Down Syndrome

18. 1. Children with Down syndrome range from severely intellectual disability to low-average intelligence. Thus, the adolescent's ability to make informed choices regarding sexual activity is limited. Long-acting contraception, such as an intrauterine device or a progestin implant, greatly reduces the risk of unwanted pregnancy. Most women with Down syndrome are fertile; however, children born to women with Down syndrome often have congenital defects. An abstinence program may not be effective due to the intellectual level of children with Down syndrome. Suggesting that the adolescent break off the relationship does not ensure that she will.

CN: Health promotion and maintenance; CL: Analyze

19. 1. Watching the child relate to his teacher and schoolwork is the best indication of how he is progressing. School involves interacting with a person who is not a relative and in a situation that is not totally familiar. Observing the client in situations with family and friends shows social relationships but does not indicate how the child is learning new intellectual skills.

CN: Health promotion and maintenance; CL: Evaluate

20. 1. The goal in working with children with intellectual disabilities is to train them to be as independent as possible, focusing on developmental skills. The child may not be capable of learning something new every day but needs to repeat what has been taught previously. Rather than encouraging more lenient behavior limits, the parents need to be strict and consistent when setting limits for the child. Most children with Down syndrome are unable to achieve age-appropriate social skills due to their disability. Rather, they are taught socially appropriate behaviors.

CN: Health promotion and maintenance; CL: Synthesize

21. 4. Nonthreatening experiences that are stimulating and interesting to the child have been observed to help raise IQ. Practices such as serving nutritious meals or letting the child play with more able children have not been supported by research as beneficial in increasing intelligence. Vasodilator medications act to increase oxygenation to the tissues, including the brain. However, these medications do not increase the child's IQ.

CN: Health promotion and maintenance; CL: Synthesize

22. 4. When teaching the parents of a child with Down syndrome, activities should focus on increasing the parents' confidence in their ability to care for the child. The parents must continue to work daily with their child. Most parents feel affection and a sense of responsibility for their child regardless of the child's limitations. Parents usually understand the child's disability on the cognitive level but have difficulty accepting it on the emotional level. As the parents' confidence in their caring abilities increases, their understanding of the child's disability also increases on all levels.

CN: Psychosocial integrity; CL: Create

The Client with a Seizure Disorder

23. 2. Phenytoin can cause gingival hyperplasia. Children taking phenytoin should brush their teeth after every meal and at bedtime, and visit their dentist on a regular basis. Drinking plenty of fluids is not required while taking phenytoin. A child on phenytoin does not need to be observed during waking hours because the seizures should be under control. Infections do not occur with an increased incidence in clients receiving phenytoin.

CN: Pharmacological and parenteral therapies; CL: Create

24. 3. During a generalized tonic-clonic seizure, the first priority is to keep the child safe and protect the child by removing any nearby objects that could cause injury. Although obtaining information about events surrounding the seizure is important, this information can be obtained later, once the child's safety is ensured. During a seizure, the child should not be moved. Although providing privacy is important, the child's safety is the priority. During a seizure, nothing should be forced into the client's mouth because this can cause severe damage to the teeth and mouth.

CN: Physiological adaptation; CL: Evaluate

25. 3. Most children who develop seizures after infancy are intellectually normal. A child with a seizure disorder needs the same experiences and opportunities to develop intellectual, emotional, and social abilities as any other child. Activity limitation is not needed. Learning disabilities are not associated with seizures. The child is able to attend public school, and social stigma is a rarity.

CN: Health promotion and maintenance; CL: Create

26. 1. A child who has generalized seizures should not participate in activities that are potentially hazardous. Even if accompanied by a responsible adult, the child could be seriously injured if a seizure were to occur during rock climbing. Someone also should accompany the child during activities in the water. At summer camps, hiking and swimming would occur most commonly as group activities, so someone should be with the child. Tennis would be considered an appropriate, nonhazardous activity for a child with generalized seizures.

 CN: Safety and infection control; CL: Synthesize

27. 4. Most febrile seizures occur in the presence of an upper respiratory infection, otitis media, or tonsillitis. Febrile seizures typically occur during a temperature rise rather than after prolonged fever. There appears to be increased susceptibility to febrile seizures within families. Infrequently, febrile seizures may lead to respiratory arrest.

 CN: Physiological adaptation; CL: Analyze

28. 2. Shivering, the body's defense against rapid temperature decrease, results in an increase in body temperature. Therefore, the parents need to take measures to stop the shivering (and the resulting increase in body temperature) by increasing the room temperature or the temperature of the child's immediate environment (such as with blankets) until the shivering stops. Then, attempts are made to lower the temperature more slowly. Shivering does not necessarily correlate with being cold. Alcohol, a toxic substance, can be absorbed through the skin. Its use is to be avoided.

 CN: Physiological adaptation; CL: Evaluate

29. 3. Phenytoin sodium is a known teratogenic agent, causing numerous fetal problems. Therefore, the adolescent should be advised to talk to the **HCP**  to see if changing the medication is possible. Additionally, anticonvulsant requirements usually increase during pregnancy. Seizures can be controlled but cannot be cured. There is a familial tendency for seizure disorders. Seizure disorders and infertility are not related.

 CN: Pharmacological and parenteral therapies; CL: Synthesize

30. 3. A toxic effect of valproic acid is liver toxicity, which may manifest with jaundice and abdominal pain. If jaundice occurs, the client needs to notify the **HCP**  as soon as possible. Diarrhea and sore throat are not common side effects of this drug. Increased appetite is common with this drug.

 CN: Pharmacological and parenteral therapies; CL: Analyze

The Client with Meningitis

31. 1. Instituting droplet precautions is the priority for a newly admitted infant with meningococcal meningitis. Acetaminophen may be ordered, but administering it does not take priority over instituting droplet precautions. Obtaining history information and orienting the parents to the unit do not take priority.

CN: Safety and infection control; CL: Application

32. 2. A child in the acute stage of meningitis is irritable and hypersensitive to loud noise and light. Therefore, extraneous noise should be minimized and bright lights avoided as much as possible. There is no need to limit conversations with the child. However, the nurse should speak in a calm, gentle, reassuring voice. The child needs gentle and calm bathing. Because of the acuteness of the infection, sponge baths would be more appropriate than tub baths. Although treatments need to be completed as quickly as possible to prevent overstressing the child, they should be performed carefully and at a pace that avoids sudden movements to prevent startling the child and subsequently increasing intracranial pressure.

CN: Basic care and comfort; CL: Synthesize

33. 1. Disseminated intravascular coagulation is characterized by skin petechiae and a purpuric skin rash caused by spontaneous bleeding into the tissues. An abnormal coagulation phenomenon causes the condition. Heparin therapy is often used to interrupt the clotting process. Edema would suggest a fluid volume excess. Cyanosis would indicate decreased tissue oxygenation. Dyspnea on exertion would suggest respiratory problems, such as pulmonary edema.

CN: Physiological adaptation; CL: Analyze

34. 2. Organisms that cause bacterial meningitis, such as pneumococci or meningococci, are commonly spread in the body by vascular dissemination from a middle ear infection. The meningitis may also be a direct extension from the paranasal and mastoid sinuses. The causative organism is a pneumococcus. A chronically draining ear is also frequently found. Bladder infections commonly are caused by *Escherichia coli*, unrelated to the development of pneumococcal meningitis. Pneumococcal meningitis is unrelated to a fractured clavicle or to septic arthritis, which is commonly

caused by *Staphylococcus aureus*, group A streptococci, or *Haemophilus influenzae*.

CN: Physiological adaptation; CL: Analyze

35. 3. Preschool-age children worry about having an intact body and become fearful of any threat to body integrity. Allowing the child to participate in required care helps protect her image of an intact body. Development of trust is the task typically associated with infancy. Additionally, allowing the child to apply a dressing over the intravenous insertion site is unrelated to the development of trust. Finding diversional activities is not a priority need for a child in this age group. Separation anxiety is more common in toddlers than in preschoolers.

CN: Health promotion and maintenance; CL: Apply

36. 83 mL/h

$$1,000 \text{ mL} \div 12 \text{ h} = 83 \text{ mL/h}$$

CN: Pharmacological and parenteral therapies; CL: Apply

37. 1,3,4. Antibiotics are indicated for the treatment of bacterial meningitis. Clients with bacterial meningitis often have increased ICP. It is necessary to maintain adequate hydration. However, infusing fluids at 1½ maintenance can increase ICP, further risking neurologic damage due to cerebral edema. Most children with meningitis are sensitive to sound, light, and stimulation. Decreasing environmental stimuli and keeping the room dim and quiet are essential. Frequent neurologic checks are necessary to monitor any changes in the child's level of consciousness. Anticonvulsants are not indicated unless the child experiences seizures as a result of the meningitis.

CN: Physiological adaptation; CL: Apply

38. 1,4,5. Irritability, bulging fontanelle, and emesis are all signs of increased ICP in an infant. A headache may be present in an infant with increased ICP; however, the infant has no way of communicating this to the parent. A headache is an indication of increased ICP in a verbal child. An infant cannot exhibit mood swings; this is indicative of increased ICP in a child or adolescent.

CN: Reduction of risk potential; CL: Apply

39. 3. The child is angry and needs a positive outlet for expression of feelings. An emotionally tense child with pent-up hostilities needs a physical activity that will release energy and frustration. Pounding on a pegboard offers this opportunity. Listening to a story does not allow the child to express emotions. It also places the child in a passive role and does not allow the child to deal with feelings in a healthy and positive way. Activities such as painting and stacking a tower of blocks require concentration and fine movements, which could add to frustration. However, if the child then knocks the tower over, doing so may help to dispel some of the anger.

CN: Health promotion and maintenance; CL: Synthesize

The Client with Near-Drowning

40. 2. Hypoxia is the primary problem because it results in brain cell damage. Irreversible brain damage occurs after 4 to 6 minutes of submersion. Hypothermia occurs rapidly in infants and children because of their large body surface area. Hypothermia is more of a problem when the child is in cold water. Although fluid aspiration occurs in most drownings and results in atelectasis and pulmonary edema, further aggravating hypoxia, hypoxia is the primary problem. Cutaneous capillary paralysis is not a problem.

CN: Physiological adaptation; CL: Analyze

41. 1. Near-drowning victims typically suffer hypoxia and mixed acidosis. The priority is to restore oxygenation and prevent further hypoxia. Here, the client has blunted sensorium but is not unconscious; therefore, delivery of supplemental oxygen with a mask is appropriate. Warming protocols and fluid resuscitation will most likely be needed to help correct acidosis, but these interventions are secondary to oxygen administration. Intubation is required if the child is comatose, shows signs of airway compromise, or does not respond adequately to more conservative therapies.

CN: Physiological adaptation; CL: Synthesize

42. 2. Guilt is a common parental response. The parents need to be allowed to express their feelings openly in a nonthreatening, nonjudgmental

atmosphere. Telling the parents that these things happen does not allow them to verbalize their feelings. Telling the parents that they should not have taken their eyes off the child blames them, possibly further contributing to their guilt. Telling the parents that they should not feel guilty denies the parents' feelings of guilt and is inappropriate. Telling the parents that they are lucky that the child will be okay does not remove the feelings of guilt.

CN: Psychosocial integrity; CL: Synthesize

The Client with Guillain-Barré Syndrome (Infectious Polyneuritis)

43. 1. The child is exhibiting symptoms associated with Guillain-Barré syndrome (infectious polyneuritis). Most children with sore throat have some difficulty swallowing, so it is important for the nurse to determine the extent of difficulty to aid in determining what action is necessary. Typically, a sore throat precedes the paralysis in clients with Guillain-Barré syndrome. Muscle tenderness is an initial symptom. Distal muscle weakness follows proximal muscle weakness, ultimately progressing to paralysis. Diet history and difficulty urinating will not contribute to assessment of the cause of a sore throat or difficulty swallowing. After determining the extent of difficulty swallowing, the nurse can obtain information about exposure to illness.

CN: Health promotion and maintenance; CL: Analyze

44. 2. With Guillain-Barré syndrome, progressive ascending paralysis occurs. Therefore, the nurse should assess the child's muscle strength bilaterally to determine the extent of involvement and progression of the illness. Assessing the child's ability to follow simple commands evaluates brain function. Range-of-motion exercises are an important part of treatment, but they are not a priority initially. Although the child may need diversional activities later, they also are not an initial priority.

CN: Physiological adaptation; CL: Synthesize

45. 3. In a child with Guillain-Barré syndrome, decreased volume and clarity of speech and decreased ability to cough voluntarily indicate ascending progression of neural inflammation, specifically affecting the cranial nerves. Inflammation of the larynx and epiglottis is manifested by

hoarseness, stridor, and dyspnea. A child with laryngeal inflammation still retains the ability to cough. Irritability, behavior changes, headache, and vomiting are common signs of increased intracranial pressure in a school-age child. Regression would be manifested by being more dependent and less able to care for self.

CN: Physiological adaptation; CL: Apply

46. 2. An ineffective breathing pattern caused by the ascending paralysis of the disorder interferes with the child's ability to maintain an adequate oxygen supply. Therefore, this nursing diagnosis takes precedence. Additionally, as the neurologic impairment progresses, it will probably have an effect on the child's ability to maintain respirations. An increased risk for infection related to an altered immune system is not associated with Guillain-Barré syndrome. Although impaired swallowing and incontinence may occur with the ascending paralysis of this disorder, oxygenation is the priority.

CN: Physiological adaptation; CL: Analyze

47. 4. Even in the absence of respiratory problems or distress, the child must be turned frequently to help prevent the cardiopulmonary complications associated with immobility, such as atelectasis and pneumonia. Maintaining the child in a supine position is unnecessary. Doing so does not prevent unnecessary nerve stimulation. In addition, maintaining a supine position may lead to stasis of secretions, placing the child at risk for pneumonia. Transferring the child to a chair will not prevent postural hypotension. However, doing so will increase vascular tone and help prevent respiratory and skin complications. During the acute disease phase, vigorous physiotherapy is contraindicated because the child may experience muscle pain and be hypersensitive to touch. Careful and gentle handling is essential.

CN: Physiological adaptation; CL: Synthesize

48. 3. Developmentally appropriate activities and therapeutic play should be used as rehabilitation modalities. Taking the child to the pool to exercise with other children indicates that the child is participating in exercise as well as engaging with other children, thus fostering development. Arguing with the sister does not address the discharge plan. Inappropriate rewards or threats should not be used to coerce a child into compliance. Although the

mother is attempting to comply with the discharge plan, bribery is an inappropriate technique to foster compliance. Missing therapy sessions delays recovery. The parents need to help set the child's schedule to ensure that she gets adequate rest to be able to follow her treatment plan.

CN: Physiological adaptation; CL: Evaluate

The Client with a Head Injury

49. 1. This client is experiencing neurologic changes consistent with increasing intracranial pressure (ICP). The nurse should first notify the **HCP** . The HCP may intubate the child to ensure a patent airway. The nurse should not lower the head of the bed as this will cause increased ICP. The nurse should ensure an adequate fluid balance. The HCP will likely prescribe hypertonic saline to draw fluid from the brain.

CN: Management of care; CL: Synthesize

50. 1. An ICP level greater than 15 mm Hg is abnormal. This child's vital signs indicate increased ICP. Mannitol is an osmotic diuretic and will decrease the child's ICP. Suctioning the child will increase the ICP. Encouraging the parent to talk to the child may be comforting but will not decrease the ICP. The priority for this child is decreasing the ICP to avoid further brain injury. The fever is likely due to the head injury and will not decrease with acetaminophen. A cooling blanket is the most effective means of reducing a fever in a client with a head injury.

CN: Reduction of risk potential; CL: Apply

51. 2. For the child with serious head trauma, a nasogastric tube is inserted initially to decompress the stomach and to prevent vomiting and aspiration. Medications would be administered intravenously in the initial period. The tube will not be used to obtain gastric specimens. Nutrition is not a priority initially. Later on, the tube may be used to administer feedings.

CN: Reduction of risk potential; CL: Apply

52. 1. Because a basilar skull fracture can involve the frontal and ethmoid bones, inserting a nasogastric tube carries the risk of introducing the tube into the cranial cavity through the fracture. An oral gastric tube is preferred for a

client with a basilar skull fracture. The tube would not be placed into the duodenum. Gastric aspirate is not routinely tested for blood unless there is an indication to suggest bleeding, such as a falling hemoglobin or visible blood in the drainage.

CN: Reduction of risk potential; CL: Synthesize

53. 3. As a rule, children demonstrate more rapid and more complete recovery from coma than do adults. However, it is extremely difficult to predict a specific outcome. Reassuring the parents that they will be kept informed helps open lines of communication and establish trust. Telling the parents that children do not do well would be extremely negative, destroying any hope that the parents might have. Telling the parents that children recover rapidly may give the parents false hopes. Telling the parents to talk to the **HCP**  ignores the parents' concerns and interferes with trust building.

CN: Physiological adaptation; CL: Synthesize

54. 2. The level of consciousness (LOC) is the best indicator of brain function. If the child's condition deteriorates, the nurse would notice changes in LOC before any other changes and should notify the **healthcare provider (HCP)**  that these changes are occurring. Changes in vital signs and pupils typically follow changes in LOC. Motor strength is primarily assessed as a voluntary function. With changes in levels of consciousness, there may be motor changes.

CN: Physiological adaptation; CL: Apply

55. 2. The unconscious child is positioned to prevent aspiration of saliva and minimize intracranial pressure. The head of the bed should be elevated, and the child should be in either the semiprone or the side-lying position. Lying prone with hips and knees slightly elevated increases intracranial pressure, as does lying on the back in the Trendelenburg position. The semi-Fowler's position with arms at the side is not the best choice.

CN: Physiological adaptation; CL: Synthesize

56. 3. Mannitol is an osmotic diuretic used to reduce intracranial pressure. The use of the drug is controversial and should be reserved to cases that do not respond to other treatments or when brain herniation is likely. Children

this sick should be on intracranial pressure (ICP) monitoring. The best indicator that the drug has produced the desired results is a reduction in the ICP. Improved levels of consciousness should follow reduced ICP. While the drug will cause increased urine output, that measurement in and of itself does not indicate successful treatment. Because the drug is being used for head injuries, not to improve urine output in acute renal failure, the child may not have visible edema.

CN: Pharmacological and parenteral therapies; CL: Evaluate

57. 2. Appearing dazed or stunned after a head injury is a symptom of a concussion. Concussion care includes removing the athlete from play and having the injury evaluated. Athletes should not return to play until they have been cleared by an HCP. Concussions require ongoing monitoring. Since the client has no signs of deterioration in neurologic function, it may best be provided by an HCP, who will follow him over time, rather than through an emergency department.

CN: Reduction of risk potential; CL: Apply

58. 2,3,4,6. Concussion recovery can be complicated by any previous brain injury, such as a previous concussion. Recovery can also be complicated by the presence of other neurologic problem, such as migraines, ADHD, and depression. Asthma and obesity have not been linked to concussion recovery.

CN: Risk reduction; CL: Analyze

59. 3. The inability to hop is not concerning because it is a milestone for a 4-year-old, not a 3-year-old. Lack of interest in toys, changes in eating habits, and increased temper tantrums that persist several weeks all require an evaluation by a neurologist or other specialist.

CN: Physiologic adaptation; CL: Analyze

60. 4. While recovery from a concussion takes time, adequate rest and limiting exertion facilitate recovery. Both physical and cognitive exertion can cause the reemergence of symptoms and delay recovery. As symptoms resolve, clients may slowly return to previous levels of activity.

CN: Risk reduction; CL: Evaluate.

The Client with a Brain Tumor

61. 2. A decreasing level of consciousness, decerebrate positioning, or Cushing's triad (elevated systolic blood pressure, decreased pulse, and decreased respiratory rate) indicates that there is pressure on the brain stem, and the client could require intubation and cardiac resuscitation unless the **healthcare provider (HCP)** 📖 can prescribe a medication or surgical procedure to reduce the intracranial pressure. Raising the head of the bed could offer some reduction in the intracranial pressure by increasing venous blood return from the head, but it is not the priority at this time. An analgesic administered at this time would mask the sign of decreasing level of consciousness and hinder assessment. An oximeter would measure the oxygen level in the blood, but not necessarily in the brain.

🔑 CN: Physiological adaptation; CL: Synthesize

62. 1. A WBC of $2,000 \text{ mm}^3$ ($2 \times 10^9/\text{L}$) is low and increases risk for infection. Meticulous handwashing is a universal precaution and the first line of defense in combating infection. A platelet count of $150,000 \text{ } \mu\text{L}$ ($150 \times 10^9/\text{L}$) is normal, so there is no need for a platelet transfusion. Mouth care will help decrease the risk of infection. However, handwashing is the priority as it will have the greatest impact on diminishing the risk of infection. An Hgb of 12.5 g/dL (125 g/L) and an HCT of 36.8% (0.37) are within normal range, so there is no need to transfuse packed red blood cells.

🔑 CN: Reduction of risk potential; CL: Analyze

63. 3. A child who has symptoms of vomiting, headaches, and problems walking needs to be evaluated by a **healthcare provider (HCP)** 📖 to determine the cause. Unexplained headaches and vomiting along with difficulty walking (e.g., ataxia) may suggest a brain tumor. Evaluation by an eye HCP would be appropriate once a complete medical evaluation has been accomplished. Psychological counseling may be indicated for this adolescent, but only after medical evaluation to determine that she is physically healthy. Meeting with the child's teachers would be appropriate after medical evaluation.

🔑 CN: Physiological adaptation; CL: Synthesize

64. 4. When a brain tumor is suspected, the child and parents are likely to be very apprehensive and anxious. It is unrealistic to expect to eliminate their fears; rather, the nurse's goal is to decrease them. Preparing both the child and family during hospitalization can help them cope with some of their fears. Although the nurse may be able to decrease some of the child's anxiety, it would be impossible to eliminate it. Children with infratentorial tumors seldom have seizures, so seizure precautions are not indicated. Although introducing the child to other children is a positive action, this action would be more appropriate once the nurse has decreased some of the child's and parents' anxiety by preparing them.

CN: Psychosocial integrity; CL: Synthesize

65. 1. The infant has opisthotonos, an indication of brain stem herniation; the nurse should notify the **HCP**  immediately and have resuscitation equipment ready. Stroking the back will not relieve the herniation or release the arching. Although the infant may also have a seizure, and padded side rails will prevent injury, the first action is to notify the HCP. Placing the child in a prone position will not relieve the herniation or release the arching.

CN: Management of care; CL: Synthesize

66. 1,2,4. Head tilt, vomiting, and lethargy are classic signs assessed in a child with a brain tumor. Clinical manifestations are the result of location and size of the tumor. Polydipsia is rare with a brain tumor. It is more often a sign of diabetes insipidus following a closed head injury. Increased appetite occurs during a growth spurt and is not necessarily a sign of a brain tumor. Increased pulse is a nonspecific sign and can occur with many illnesses, cardiac anomalies, fever, or exercise. Slow heart rate is more associated with increased intracranial pressure seen with brain tumors

CN: Physiological adaptation; CL: Analyze

67. 3. After surgery for an infratentorial tumor, the child is usually positioned flat on either side, with the head and neck in midline and the body slightly extended. Pillows against the back, not the head, help maintain position. Such a position helps avoid pressure on the operative site. Placing the child in a prone or semi-Fowler's position will cause pressure on the operative site. The Trendelenburg position is usually contraindicated because

keeping the head below the level of the heart increases intracranial pressure as well as the risk of hemorrhage.

CN: Physiological adaptation; CL: Synthesize

68. 1. Hypercapnia, hypoxia, and acidosis are potent cerebral vasodilating mechanisms that can cause increased intracranial pressure. Lowering the carbon dioxide level and increasing the oxygen level through hyperventilation is the most effective short-term method of reducing intracranial pressure. Although ensuring a patent airway is important, this is not accomplished by manual hyperventilation. Manual hyperventilation does not lower the arousal level; in fact, the arousal level may increase. Manual hyperventilation is used to reduce hypoxia, not produce it.

CN: Reduction of risk potential; CL: Evaluate

69. 3. Glucose in this clear, colorless fluid indicates the presence of cerebrospinal fluid. Excessive fluid leakage should be reported to the **HCP**. The nurse should not change the dressing of a postoperative craniotomy client unless instructed to do so by the surgeon. Ordinarily, the head of the bed would not be elevated because this would put pressure on the sutures. The nurse should notify the HCP after testing the fluid for glucose.

CN: Reduction of risk potential; CL: Synthesize

70. 1. It is not uncommon for a child to be concerned about a change in appearance when the entire head or only part of the head has been shaved. The child should be encouraged to participate in decisions about her care when possible. Asking her if she would like to wear a hat is one way to encourage this participation. Reassuring the child that her hair will grow back does not address the immediate change in appearance, and it ignores the child's current feelings. Explaining that this type of reaction is normal does not address the child's feelings. The child needs to be able to express feelings and be involved in care as much as possible. Buying the child a wig as a surprise does not address the child's feelings and does not allow her to participate in decision making. Rather, the parents should ask the child if she would like a wig and then work with the child to determine what kind of wig she would like.

CN: Psychosocial integrity; CL: Synthesize

71. 1. Parents of a child who has undergone neurosurgery can easily become overprotective. Yet, the parents must foster independence in the convalescing child. It is important for the child to resume age-appropriate activities, and parents play an important role in encouraging this. Statements about going back to school would be expected. Parents want the child to return to normal activities after a serious illness or injury as a sign that the child is doing well.

CN: Psychosocial integrity; CL: Evaluate

The Client with a Spinal Cord Injury

72. 2. The adolescent's signs and symptoms suggest a spinal cord injury. A client with suspected spinal cord injury should not be moved until the spine has been immobilized. Removing the helmet could further aggravate a spinal cord injury. The nurse could assess for abdominal trauma, but only if it can be done without moving the adolescent.

CN: Reduction of risk potential; CL: Synthesize

73. 1. In spinal cord injury, temperature regulation is lost below T3. Body temperature must be maintained by adjusting room temperature or bed linens, such as covering the client's legs with blankets. Coolness of the extremities is an expected finding. Therefore, it is not necessary to notify the **HCP**  immediately. Repositioning the client's legs does not alleviate the temperature regulation problem and could be harmful, considering the client's diagnosis. Moving the legs before the spine is stabilized could lead to further cord damage. Laying the client flat will not increase the warmth to the legs and feet.

CN: Physiological adaptation; CL: Synthesize

74. 3. A thoracic spinal cord injury involves the muscles of the lower extremities, bladder, and rectum. Paralytic ileus often occurs as a result of decreased gastrointestinal muscle innervation. The nurse evaluates this by auscultating the abdomen. Because the client has a thoracic spinal cord injury, the client may not feel abdominal cramping. Additionally, auscultation would provide no evidence of cramping. Hyperactive bowel sounds would be evidenced with increased peristalsis; peristalsis would

probably be diminished with this injury. Profuse diarrhea, resulting from increased peristalsis, would not be an expected finding. Diarrhea would be more commonly associated with a gastrointestinal infection.

 CN: Physiological adaptation; CL: Analyze

75. 3. Spinal shock causes a loss of reflex activity below the level of the injury, resulting in bladder atony and flaccid paralysis. When the reflex arc returns, it tends to be overactive, resulting in spasticity. The reflexes and bladder become hypertonic during this phase of spinal shock resolution; sensation does not return. A widened pulse pressure is not associated with resolution of spinal shock.

 CN: Physiological adaptation; CL: Evaluate

76. 1. After a catastrophic injury, individuals commonly experience grief. Initially, the person experiences denial, the most common response. With gradual awareness of the situation, anger commonly occurs. The child is demonstrating anger, not rebellion, as he gradually becomes aware of his situation. Rebellion is the child's way to maintain autonomy and individuality. It is a reaction to rigid rules. Examples include refusing to follow a treatment protocol when the child had no input and running away. Sensory overload would cause the child to be irritable and tired and to have difficulty sleeping. Too much attention usually would lead to irritability, difficulty sleeping, and mood swings.

 CN: Psychosocial integrity; CL: Analyze

77. 1. The adolescent is exhibiting signs of autonomic dysreflexia, a generalized sympathetic response usually caused by bladder or bowel distention. Immediate treatment involves eliminating the cause. Because bladder distention is a common cause of this problem, the nurse should immediately determine the patency of the indwelling (Foley) catheter. Lowering the head below the knees would increase the blood pressure and is contraindicated because of the spinal cord injury. Lying flat will not decrease blood pressure. Epinephrine is contraindicated because it elevates blood pressure and therefore can exacerbate the problem.

 CN: Physiological adaptation; CL: Synthesize

Managing Care, Quality, and Safety of Children with Neurologic Health Problems

78. 4. Bacterial meningitis is caused by one of three organisms, *H. influenzae* type b, *Neisseria meningitidis*, or *Streptococcus pneumoniae*. All three organisms may be transmitted through contact with respiratory droplets. These droplets are heavy and typically fall within 3 feet (91.4 cm) of the client. Droplet precautions require, in addition to standard (routine) precautions, that **HCPs** wear masks when coming into close contact with the client. Standard or routine precautions, previously referred to as universal precautions, are general measures used for all clients. Contact precautions are used when direct or indirect contact with the client causes disease transmission. Gowns and gloves are needed but not masks. Airborne precautions differ from droplet in that the particles are smaller and may stay suspended in the air for longer periods of time. These clients require negative pressure rooms, and all healthcare workers must wear respirators.

CN: Safety and infection control; CL: Apply

79. 3,4,5. Using only oral syringes to administer oral medications reduces the chance that the medication will be given intravenously. The use of smart pumps alone is not enough to prevent IV fluid administration. An additional measure that pediatric floors can institute to prevent accidental fluid overload is to use smaller IV fluid bags, such as 250 mL. Whenever a medication comes in multiple concentrations and doses, there is risk of administering the wrong dose. The use of pediatric satellite pharmacies with pediatric pharmacists greatly increases the safety of medication administration. Any time steps are added to the medication administration process, there is one more place where an error might occur.

CN: Safety and infection control; CL: Synthesize

80. 4. The coating on an extended-release medication helps assure slow absorption of the medication. If the nurse crushes the medication, the medication may enter the client's system too quickly and result in toxic levels. The only appropriate action is to contact the prescriber and ask that the prescription be changed. Cutting the medication or trying to dissolve a whole tablet would have similar results as crushing it. Carbamazepine comes as an

oral suspension, but it is not extended release. Therefore, a prescription would be needed to address dosing if switching to this form.

CN: Safety and infection control; CL: Synthesize

81. 1. A poster presentation is an eye-catching way to disseminate information that can be used to educate nurses on all shifts. The addition of the posttest will verify that the poster information has been received. Because of the large volume of e-mails the typical employee receives, information sent this way might be overlooked. If several nurses are observed not using the most current practice, it is quite possible many more do not understand it. Thus, a larger-scale plan is needed. Posting an article will not alone assure that the information is read.

CN: Reduction of risk potential; CL: Create

82. 1. The child is exhibiting signs and symptoms of increased intracranial pressure (ICP). A lumbar puncture is contraindicated in children with increased ICP due to the risk of herniation. Magnetic resonance imaging and a computerized tomography scan are indicated in children with suspected increased ICP. Radiology studies will allow visualization of the cause of the increased ICP, such as inflammation, a tumor, or hemorrhage. An arterial blood draw is not indicated in this client. However, there is no contraindication for performing an arterial blood draw on a child with increased ICP.

CN: Reduction of risk potential; CL: Analyze

83. 2. IV lorazepam is the benzodiazepine of choice for treating prolonged seizure activity. IV benzodiazepines act to potentiate the action of the gamma-aminobutyric acid (GABA) neurotransmitter, stopping seizure activity. If an IV is not available, rectal diazepam is the benzodiazepine of choice. The child does have a low-grade fever; however, this is likely caused by the excessive motor activity. The primary goal for the child is to stop the seizure in order to reduce neurologic damage. Benzodiazepines are used for the initial treatment of prolonged seizures. Once the seizure has ended, a loading dose of fosphenytoin or phenobarbital is given.

CN: Pharmacological and parenteral therapies; CL: Apply

The Child with Musculoskeletal Health Problems

- The Client with Torticollis, Legg-Calvé-Perthes Disease, and Musculoskeletal Dysfunction
- The Client with Cerebral Palsy
- The Client with Duchenne's Muscular Dystrophy
- The Client with Developmental Dysplasia of the Hip
- The Client with Congenital Clubfoot
- The Client with Juvenile Idiopathic Arthritis
- The Client with a Fracture
- The Client with Osteomyelitis
- The Client with Scoliosis
- Managing Care, Quality, and Safety of Children with Musculoskeletal Health Problems
- Answers, Rationales, and Test-Taking Strategies

The Client with Torticollis, Legg-Calvé-Perthes Disease, and Musculoskeletal Dysfunction

1. In planning the discharge for a newborn diagnosed with torticollis (wry neck), the nurse should:

- ☐ **1.** teach the parent the side effects of botulinum toxin.
- ☐ **2.** coordinate outpatient physical therapy.
- ☐ **3.** verify the date for corrective surgery.
- ☐ **4.** demonstrate the use of positioning wedges for sleep.

2. A child who limps and has pain has been found to have Legg-Calvé-Perthes disease. What should the nurse expect to include in the child's plan of

care?

- ☐ 1. initiation of pain control measures, especially at night when acute
- ☐ 2. promotion of ambulation despite child's discomfort in the affected hip
- ☐ 3. prevention of flexion in the affected hip and knee
- ☐ 4. avoidance of weight bearing on the head of the affected femur

3. When planning home care for the child with Legg-Calvé-Perthes disease, what should be the **primary** focus for family teaching?

- ☐ 1. need for intake of protein-rich foods
- ☐ 2. gentle stretching exercises for both legs
- ☐ 3. management of the corrective appliance
- ☐ 4. relaxation techniques for pain control

4. At the 2-week well-child visit, a parent states, "My baby seems to keep his head tilted to the right." The nurse should further assess the:

- ☐ 1. fontanelle.
- ☐ 2. cervical vertebrae.
- ☐ 3. trapezius muscle.
- ☐ 4. sternocleidomastoid muscle.

5. An adolescent tells the nurse that the area below his knee has been hurting for several weeks. The nurse should obtain history information about participation in which sport?

- ☐ 1. soccer
- ☐ 2. golf
- ☐ 3. diving
- ☐ 4. swimming

6. An adolescent is on the football team and practices in the morning and afternoon before school starts for the year. The temperature on the field has been high. The school nurse has been called to the practice field because the adolescent is now reporting that he has muscle cramps, nausea, and dizziness. Which action should the school nurse do **first**?

- ☐ 1. Administer cold water with ice cubes.
- ☐ 2. Take the adolescent's temperature.

- ☐ 3. Have the adolescent lie supine.
- ☐ 4. Move the adolescent to a cool environment.

The Client with Cerebral Palsy

7. During a developmental screening, the nurse finds that a 3-year-old child with cerebral palsy has arrested social and language development. The nurse tells the family:

- ☐ 1. "This is a sign the cerebral palsy is progressing."
- ☐ 2. "Your child has reached his maximum language abilities."
- ☐ 3. "I need to refer you for more developmental testing."
- ☐ 4. "We need to modify your therapy plan."

8. A child with spastic cerebral palsy is to begin botulinum toxin type A injections. Which treatment goals should the healthcare team set for the child related to botulinum toxin? Select all that apply.

- ☐ 1. improved nutritional status
- ☐ 2. decreased pain from spasticity
- ☐ 3. improved motor function
- ☐ 4. enhanced self-esteem
- ☐ 5. reduced caregiver strain and improved self-care
- ☐ 6. decreased speech impediments

9. The nurse judges that the mother understands the term *cerebral palsy* when she describes it as a term applied to impaired movement resulting from which factor?

- ☐ 1. injury to the cerebrum caused by viral infection
- ☐ 2. malformed blood vessels in the ventricles caused by inheritance
- ☐ 3. nonprogressive brain damage caused by injury
- ☐ 4. inflammatory brain disease caused by metabolic imbalances

10. When assessing the development of a 15-month-old child with cerebral palsy, which milestones should the nurse expect a typically developing toddler of this age to have achieved?

- ☐ 1. walking up steps

- ☐ 2. using a spoon
- ☐ 3. copying a circle
- ☐ 4. putting a block in a cup

11. The parent of a child with spastic cerebral palsy and a communication disorder tells the nurse, “He seems so restless. I think he is in pain.” Which action is **most** indicated?

- ☐ 1. Assess the child for pain using the faces, legs, activity, cry, consolability (FLACC) scale.
- ☐ 2. Assess the child for pain using the pediatric FACES scale.
- ☐ 3. Administer prescribed pain medication.
- ☐ 4. Notify the healthcare provider (HCP) of the change in behavior.

12. The parent asks the nurse whether a child with hemiparesis due to spastic cerebral palsy will be able to walk normally because he can pull - himself to a standing position. Which response by the nurse would be **most** appropriate?

- ☐ 1. “Ask your healthcare provider what he or she thinks at your next appointment.”
- ☐ 2. “Being able to pull to a stand really only tells us his upper-body strength is good”
- ☐ 3. “It is difficult to predict, but his ability to bear weight is a positive factor.”
- ☐ 4. “If he really wants to walk, and works hard, he probably will eventually.”

13. The nurse assesses the family’s ability to cope with the child’s cerebral palsy. Which action should alert the nurse to the possibility of their inability to cope with the disease?

- ☐ 1. limiting interaction with extended family and friends
- ☐ 2. learning measures to meet the child’s physical needs
- ☐ 3. requesting teaching about cerebral palsy in general
- ☐ 4. seeking advice on coping on social media

The Client with Duchenne’s Muscular Dystrophy

14. The mother of a child with Duchenne's muscular dystrophy asks about the chance that her next child will have the disease. The nurse responds based on the understanding of what information?

- ☐ 1. Sons have a 50% chance of being affected.
- ☐ 2. Daughters have a 1 in 4 chance of being carriers.
- ☐ 3. Each child has a 1 in 4 chance of developing the disease.
- ☐ 4. Each child has a 50% chance of being a carrier.

15. A nurse is making an initial visit to a family with a 3-year-old child with early Duchenne's muscular dystrophy. Which finding is expected when assessing this child?

- ☐ 1. contractures of the large joints
- ☐ 2. enlarged calf muscles
- ☐ 3. difficulty riding a tricycle
- ☐ 4. atrophied muscles

16. The nurse observes as a child with Duchenne's muscular dystrophy attempts to rise from a sitting position on the floor. After attaining a kneeling position, the child "walks" his hands up his legs to stand. The nurse documents this as which sign?

- ☐ 1. Galeazzi's sign
- ☐ 2. Goodell's sign
- ☐ 3. Goodenough's sign
- ☐ 4. Gower's sign

17. When developing the plan of care for a child with early Duchenne's muscular dystrophy, which nursing goal is the **priority**?

- ☐ 1. Encourage early wheelchair use.
- ☐ 2. Foster social interactions.
- ☐ 3. Maintain function of unaffected muscles.
- ☐ 4. Prevent circulatory impairment.

18. When interacting with the parent of a child who has Duchenne's muscular dystrophy, the nurse observes behavior indicating that the parent may feel guilty about the child's condition. The nurse interprets this behavior as guilt stemming from which factor?

- ☐ 1. the terminal nature of the disease
- ☐ 2. the dependent behavior of the child
- ☐ 3. the genetic mode of transmission
- ☐ 4. the sudden onset of the disease

19. The nurse teaches the parent of a young child with Duchenne's muscular dystrophy about the disease and its management. Which statement by the parent indicates successful teaching?

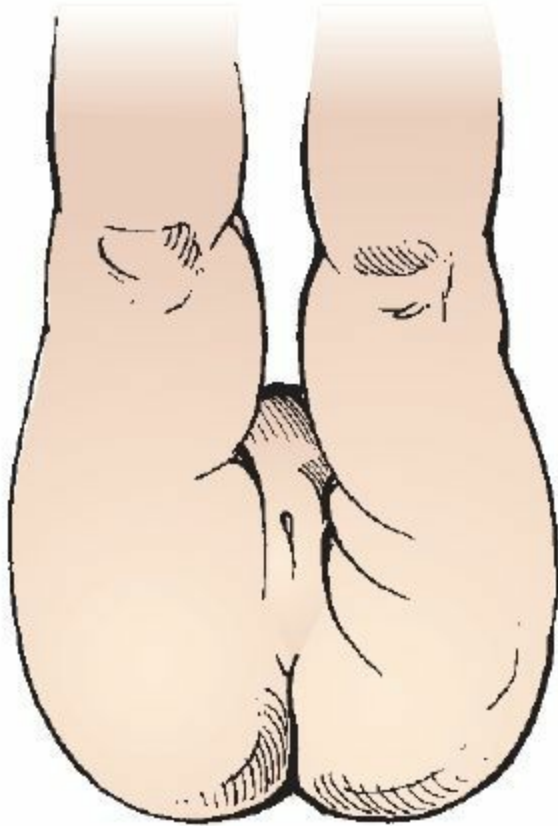

- ☐ 1. "My son will probably be unable to walk independently by the time he is 9 to 11 years old."
- ☐ 2. "Muscle relaxants are effective for some children; I hope they can help my son."
- ☐ 3. "When my son is a little older, he can have surgery to improve his ability to walk."
- ☐ 4. "I need to help my son be as active as possible to prevent progression of the disease."

The Client with Developmental Dysplasia of the Hip

20. A 16-month-old child is seen in the clinic for a checkup for the first time. The nurse notices that the toddler limps when walking. Which would be appropriate to use when assessing this toddler for developmental dysplasia of the hip?

- ☐ 1. Ortolani's maneuver
- ☐ 2. Barlow's maneuver
- ☐ 3. Adam's position
- ☐ 4. Trendelenburg's sign

21. The nurse is assessing the infant shown in the figure. On observing the client from this angle, the nurse should document that this infant has which finding?

- ☐ 1. Ortolani's "click"
- ☐ 2. limited abduction
- ☐ 3. Galeazzi's sign
- ☐ 4. asymmetric gluteal folds

22. The nurse teaches the parents of an infant with developmental dysplasia of the hip how to handle their child in a Pavlik harness. Which care is **most** appropriate?

- ☐ 1. Fit the diaper under the straps.
- ☐ 2. Leave the harness off while the infant sleeps.
- ☐ 3. Check for skin redness under straps every other day.
- ☐ 4. Put powder on the skin under the straps every day.

23. When developing the teaching plan for parents using the Pavlik harness with their child, what should be the nurse's **initial** step?

- ☐ 1. Assess the parents' current coping strategies.
- ☐ 2. Determine the parents' knowledge about the device.
- ☐ 3. Provide the parents with written instructions.

- ☐ 4. Give the parents a list of community resources.

24. When teaching the family of an older infant who has had a spica cast applied for developmental dysplasia of the hip, which information should the nurse include when describing the abduction stabilizer bar?

- ☐ 1. It can be adjusted to a position of comfort.
- ☐ 2. It is used to lift the child.
- ☐ 3. It adds strength to the cast.
- ☐ 4. It is necessary to turn the child.

25. A parent asks the nurse about using a car seat for a toddler who is in a hip spica cast. The nurse should tell the parent:

- ☐ 1. "You can use a seat belt because of the spica cast."
- ☐ 2. "You will need a specially designed car seat for your toddler."
- ☐ 3. "You can still use the car seat you already have."
- ☐ 4. "You will need to get a special release from the police so that a car seat will not be needed."

The Client with Congenital Clubfoot

26. The nurse is discharging a baby with clubfoot who has had a cast applied. The nurse should provide additional teaching to the parents if they state:

- ☐ 1. "I should call if I see changes in the color of the toes under the cast."
- ☐ 2. "I should use a pillow to elevate my child's foot as he sleeps."
- ☐ 3. "My baby will need a series of casts to fix her foot."
- ☐ 4. "Having a cast should not prevent me from holding my baby."

27. The parents of a neonate born with congenital clubfoot express feelings of helplessness and guilt and are exhibiting anxiety about how the neonate will be treated. Which action by the nurse would be **most** appropriate initially?

- ☐ 1. Ask them to share these concerns with the healthcare provider (HCP).
- ☐ 2. Arrange a meeting with other parents whose infants have had successful clubfoot treatment.
- ☐ 3. Discuss the problem with the parents and the current feelings that they

are experiencing.

- ☐ 4. Suggest that they make an appointment to talk things over with a counselor.

28. After teaching the parents of an infant with clubfoot requiring application of a plaster cast how to care for the cast, which statement would indicate that the parents have understood the teaching?

- ☐ 1. "If the cast becomes soiled, we will clean it with soap and water."
- ☐ 2. "We will elevate the leg with the cast on pillows so the leg is above heart level."
- ☐ 3. "We will check the color and temperature of the toes of the casted leg frequently."
- ☐ 4. "The petals on the edge of the cast can be removed after the first 24 hours."

The Client with Juvenile Idiopathic Arthritis

29. The parent of a preschool-age child with a tentative diagnosis of juvenile idiopathic arthritis (JIA) asks about a test to definitively diagnose JIA. The nurse's response is based on knowledge of what information?

- ☐ 1. The latex fixation test is diagnostic.
- ☐ 2. An increased erythrocyte sedimentation rate is diagnostic.
- ☐ 3. A positive synovial fluid culture is diagnostic.
- ☐ 4. No specific laboratory test is diagnostic.

30. The parents of a child just diagnosed with juvenile idiopathic arthritis (JIA) tell the nurse that the diagnosis frightens them because they know nothing about the prognosis. What information should the nurse include when teaching the parents about the disease?

- ☐ 1. The more joints affected, the more severe the disease will be.
- ☐ 2. Many affected children go into long remissions but have severe deformities.
- ☐ 3. The disease usually progresses to crippling rheumatoid arthritis.
- ☐ 4. Most affected children recover completely within a few years.

31. The mother of a 4-year-old child with juvenile idiopathic arthritis

(JIA) is worried that her child will have to stop attending preschool because of the illness. Which response by the nurse would be **most** appropriate?

- ☐ 1. "It may be difficult for your child to attend school because of the side effects of the medications he will be prescribed."
- ☐ 2. "Your child should be encouraged to attend school, but he will need extra time to work out early morning stiffness."
- ☐ 3. "You should keep your child at home from school whenever he experiences discomfort or pain in his joints."
- ☐ 4. "Your child will probably need to wear splints and braces so that his joints will be supported properly."

32. A preschool-age child with juvenile idiopathic arthritis (JIA) has become withdrawn, and the mother asks the nurse what she should do. Which suggestion by the nurse would be **most** appropriate?

- ☐ 1. Introduce the child to other children her age who also have JIA.
- ☐ 2. Tell the mother to spend extra time with the child and less time with her other children.
- ☐ 3. Recommend that the mother send the child to see a counselor for therapy.
- ☐ 4. Encourage the mother to be supportive and understanding of the child.

33. Nonsteroidal anti-inflammatory drugs are the first choice in treating a child with juvenile idiopathic arthritis. Which adverse effects should the nurse include in the teaching plan for the parents? Select all that apply.

- ☐ 1. weight gain
- ☐ 2. abdominal pain
- ☐ 3. blood in the stool
- ☐ 4. folic acid deficiency
- ☐ 5. reduced blood clotting ability

34. What information should the nurse include when developing the teaching plan for the parents of a child with juvenile idiopathic arthritis who is being treated with naproxen?

- ☐ 1. Anti-inflammatory effect will occur in approximately 8 weeks.
- ☐ 2. Within 24 hours, the child will have anti-inflammatory relief.

- ☐ 3. The nurse should be called before giving the child any over-the-counter medications.
- ☐ 4. If a dose is forgotten or missed, that dose is not made up.

The Client with a Fracture

35. A 10-year-old has 5 lb (2.27 kg) of Buck's extension traction on his left leg. What finding should the nurse assess the child for? Select all that apply.

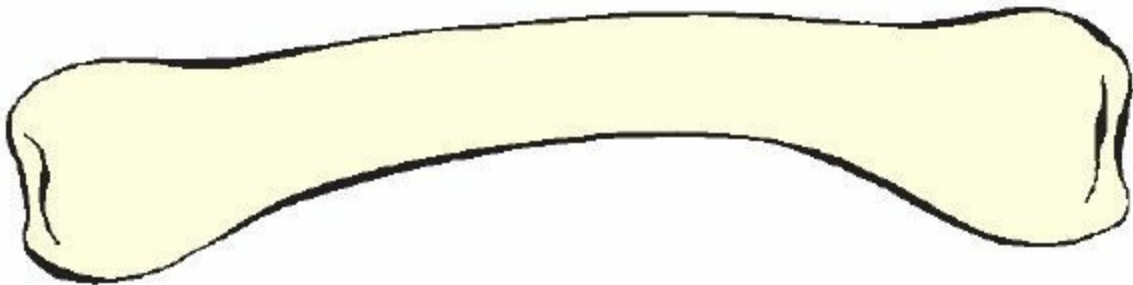

- ☐ 1. dryness of the skin, by removing the foam wraps and boot
- ☐ 2. alignment of the shoulder, hips, and knees
- ☐ 3. frayed rope near pulleys
- ☐ 4. correct amount of traction weight on fracture
- ☐ 5. pressure on the coccyx

36. A 14-year-old has just had a plaster cast placed on his lower left leg. To provide safe cast care, the nurse should:

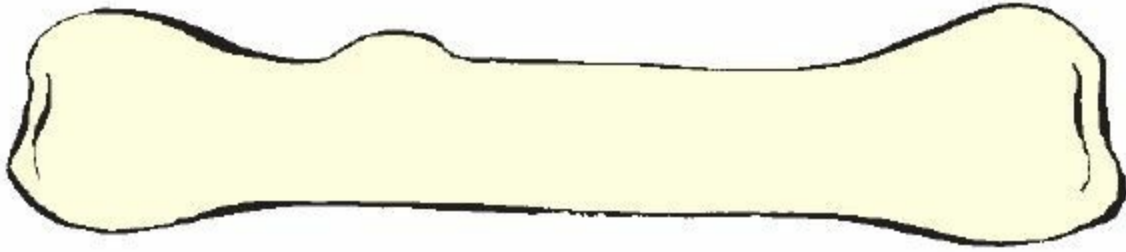

- ☐ 1. petal the cast as soon as it is put on.
- ☐ 2. keep the child in the same position for 24 hours until the cast is dry.
- ☐ 3. use only the palms of the hand when handling the cast.
- ☐ 4. notify the healthcare provider (HCP) if the client feels heat.

37. The nurse is explaining the nature of the fracture to the parents of a 10-year-old who has a greenstick fracture. Which drawing should the nurse choose to explain the fracture to the parents?

- ☐ 1.

- ☐ 2.

☐ 3.

☐ 4.

38. A 9-year-old is given morphine for postoperative pain. As the nurse is assessing the client for pain 4 hours later, his parent leaves the room, and the child begins to cry. The nurse's initial assessment of the child's pain is that he is:

- ☐ 1. not in pain because the crying began after the parent leaves.
- ☐ 2. less tolerant of pain because he is upset.
- ☐ 3. in pain because he is crying.
- ☐ 4. not in pain because he was medicated 4 hours ago.

39. A 13-year-old is having surgery to repair a fractured left femur. As a part of the preoperative safety checklist, what should the nurse do?

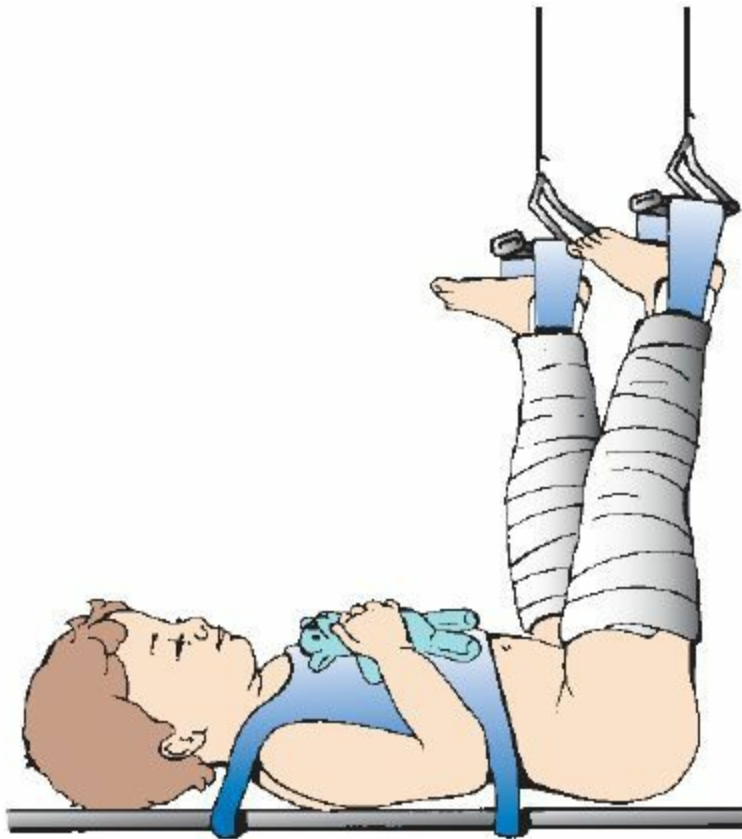

- ☐ 1. Ask the teen to point to the surgery site.
- ☐ 2. Verify that the site, side, and level are marked.
- ☐ 3. Ask the parents if they have signed the operative permit.

- ☐ 4. Restate the surgery risks to the parents.

40. A child is admitted with a fracture of the femur and placed in skeletal traction. What should the nurse assess **first**?

- ☐ 1. the pull of traction on the pin
- ☐ 2. the Ace bandage
- ☐ 3. the pin sites for signs of infection
- ☐ 4. the dressings for tightness

41. The nurse is caring for a child in Bryant's traction (see figure). The nurse should:

- ☐ 1. adjust the weights on the legs until the buttocks rest on the bed.
- ☐ 2. provide frequent skin care.
- ☐ 3. place a pillow under the buttocks.
- ☐ 4. remove the elastic leg wraps every 8 hours for 10 minutes.

42. A preschooler with a fractured femur of the left leg in traction tells the nurse that his leg hurts. It is too early for pain medication. The nurse should:

- ☐ 1. place a pillow under the child's buttocks to provide support.
- ☐ 2. remove the weight from the left leg.
- ☐ 3. assess the feet for signs of neurovascular impairment.
- ☐ 4. reposition the pulleys so the traction is looser.

43. The nurse in the emergency department is caring for a 3-year-old child with a fractured humerus. The child is crying and screaming, "I hate you!" Which action would be **most** appropriate?

- ☐ 1. Tell the parents they will need to wait out in the lobby.
- ☐ 2. Ask the charge nurse to assign this client to another nurse.
- ☐ 3. Reassure the parents that this is a normal behavior under the circumstances.
- ☐ 4. Ask the parents to discipline the child so that the team can treat her.

44. After a plaster cast has been applied to the arm of a child with a fractured right humerus, the nurse completes discharge teaching. The nurse should evaluate the teaching as successful when the mother agrees to seek medical advice if the child experiences which symptom?

- ☐ 1. inability to extend the fingers on the right hand
- ☐ 2. vomiting after the cast is applied
- ☐ 3. coolness and dampness of the cast after 5 hours
- ☐ 4. fussiness with statements that the cast is heavy

45. The nurse should teach the parent of a child who has a new cast for a fractured radius to do which intervention for the first few days at home?

- ☐ 1. Use a hair dryer to dry the cast more quickly.
- ☐ 2. Have the child refrain from strenuous activities.
- ☐ 3. Check movement and sensation of the child's fingers once a day.
- ☐ 4. Administer acetaminophen every 8 to 12 hours for discomfort.

46. While assessing a 3-year-old child who has had an injury to the leg, has pain, and refuses to walk, the nurse notes that the child's left thigh is swollen. What should the nurse do **next**?

- ☐ 1. Assess the neurologic status of the toes.
- ☐ 2. Determine the circulatory status of the upper thigh.
- ☐ 3. Obtain the child's vital signs.

- ☐ 4. Notify the healthcare provider (HCP) immediately.

47. Anticipating that a 3-year-old child in traction will have need for diversion, what should the nurse offer the child?

- ☐ 1. a video game
- ☐ 2. blocks
- ☐ 3. hand puppets
- ☐ 4. remote-controlled car

48. The parents of a child who requires skeletal traction are unable to visit their child for more than 1 hour a day because there are five other children at home and both parents work outside of the home. The nurse recognizes expressions of guilt in both parents. To help alleviate this guilt, the nurse should make which statement?

- ☐ 1. "I am sure you feel guilty about not being able to visit often."
- ☐ 2. "It is important that you visit even for 1 hour."
- ☐ 3. "Not all parents can stay all the time."
- ☐ 4. "Perhaps you could take turns visiting for a bit longer."

49. The child in a new hip spica cast seems to be adjusting to the cast, except that after each meal the child tells the nurse that the cast is too tight. What should the nurse plan to do?

- ☐ 1. Administer a laxative prior to each meal.
- ☐ 2. Offer smaller, more frequent meals.
- ☐ 3. Give the child a mechanical soft diet.
- ☐ 4. Offer the child more fruits and grains.

50. The nurse is helping a family plan for the discharge of their child who will be going home in a spica cast. Which information would be **most** important for the nurse to consider?

- ☐ 1. The bathrooms are all on the second floor.
- ☐ 2. The child's bedroom is on the second floor.
- ☐ 3. A 16-year-old sister will care for the child during the day.
- ☐ 4. There are three steps up to the front door.

51. The nurse is measuring a child for crutches. What factors should the

nurse consider? Select all that apply.

- ☐ 1. type of gait child will be using
- ☐ 2. degree of child's elbow flexion
- ☐ 3. space above the crutch to child's axilla
- ☐ 4. weight of the child
- ☐ 5. whether child has to use the stairs

The Client with Osteomyelitis

52. During the initial assessment of a child admitted to the pediatric unit with osteomyelitis of the left tibia, when assessing the area over the tibia, which is an expected finding?

- ☐ 1. diffuse tenderness
- ☐ 2. decreased pain
- ☐ 3. increased warmth
- ☐ 4. localized edema

53. A child is to receive IV antibiotics for osteomyelitis. Before the initial dose of antibiotics can be given, the nurse confirms that a blood sample for which test has been drawn?

- ☐ 1. creatinine
- ☐ 2. culture
- ☐ 3. hemoglobin
- ☐ 4. white blood count

54. A child is being treated with vancomycin 40 mg/kg/day IV divided into three doses for osteomyelitis. The healthcare provider (HCP) has prescribed drug protocol management by pharmacy and a trough vancomycin level 30 minutes before the third dose scheduled for 09:00 hours. The laboratory report returns prior to the third dose:

Laboratory Results	
0830 Vancomycin 7 mcg/mL (4.8 μ mol/L) **	Therapeutic range 10–15 mcg/mL (6.9 to 10.4 μ mol/L).

The nurse should:

- ☐ 1. administer the 09:00 dose.
- ☐ 2. notify the healthcare provider (HCP).
- ☐ 3. notify the pharmacist.
- ☐ 4. draw a peak drug level.

55. The nurse is caring for a child with osteomyelitis who will be receiving high-dose intravenous antibiotic therapy for 3 to 4 weeks. What should the nurse plan to monitor?

- ☐ 1. blood glucose level
- ☐ 2. thrombin times
- ☐ 3. urine glucose level
- ☐ 4. urine specific gravity

56. To meet the developmental needs of an 8-year-old child who is confined to home with osteomyelitis, what goal should the nurse include in the care plan?

- ☐ 1. Encourage the child to communicate with schoolmates.
- ☐ 2. Encourage the parents to stay with the child.
- ☐ 3. Allow siblings to visit freely throughout the day.
- ☐ 4. Talk to the child about his interests twice daily.

57. A child with newly diagnosed osteomyelitis has nausea and vomiting. The parent wishes to give the child ginger cookies to help control the nausea. The nurse should tell the parent:

- ☐ 1. “You can try them and see how he does.”

- ☐ 2. "I will need to get a prescription."
- ☐ 3. "Your child needs medication for the vomiting."
- ☐ 4. "We discourage the use of home remedies in children."

The Client with Scoliosis

58. When assessing an adolescent for scoliosis, what should the nurse ask the client to do?

- ☐ 1. Bend forward at the waist with arms hanging freely.
- ☐ 2. Lie flat on the floor and extend the legs straight from the trunk.
- ☐ 3. Sit in a chair while lifting the feet and legs to a right angle with the trunk.
- ☐ 4. Stand against a wall while pressing the length of the back against the wall.

59. The nurse determines that teaching about the correct use of a Boston brace to treat scoliosis has been effective if the child and family state they will remove the brace at which times?

- ☐ 1. when bathing, for about 1 hour per day
- ☐ 2. while eating, for a total of 3 hours a day
- ☐ 3. during school, for about 8 hours a day
- ☐ 4. when sleeping, for a total of 10 hours a day

60. When teaching the child with scoliosis being treated with a Boston brace about exercises, the nurse explains that the exercises are performed primarily for what reason?

- ☐ 1. to decrease back muscle spasms
- ☐ 2. to improve the brace's traction effect
- ☐ 3. to prevent spinal contractures
- ☐ 4. to strengthen the back and abdominal muscles

61. A 10-year-old with scoliosis has to wear a brace. The nurse should develop a teaching plan with the client to include which instruction?

- ☐ 1. Wear the brace during waking hours.
- ☐ 2. Use lotions to relieve skin irritations.

- ☐ 3. Wear a form-fitting t-shirt under the brace.
- ☐ 4. Bathe the skin under the brace once per week.

Managing Care, Quality, and Safety of Children with Musculoskeletal Health Problems

62. A child with spastic cerebral palsy receiving intrathecal baclofen therapy is admitted to the pediatric floor with vomiting and dehydration. The family tells the nurse that they were scheduled to refill the baclofen pump today but had to cancel the appointment when the child became ill. The nurse should:

- ☐ 1. explain that the medication should be discontinued during illness.
- ☐ 2. arrange for the pump to be refilled in the hospital.
- ☐ 3. reschedule the pump refill for the day of discharge.
- ☐ 4. instruct caregivers to call for a refill when the low-volume alarm sounds.

63. Which procedures can the nurse working on a pediatric floor safely delegate to the licensed practical/vocational nurse (LPN/VN)? Select all that apply.

- ☐ 1. refilling a baclofen pump
- ☐ 2. administering gastrostomy tube feedings
- ☐ 3. inserting hearing aids
- ☐ 4. giving an IV push medication
- ☐ 5. calling the morning blood sugars to the healthcare provider (HCP)

64. An 8-year-old child with juvenile idiopathic arthritis (JIA) is being admitted to the hospital for evaluation of progressively increasing symptoms. The child weighs 60 lb (27 kg) and is 50 inches (127 cm) tall. The nurse is reconciling the medications the parent brought from home with the medications prescribed. What should the nurse do? (See chart.)

Prescriptions

Home meds	Prescribed meds
Ibuprofen tablet 200 mg PO 4× day (for arthritis) Purchased over the counter	Ibuprofen tablet 200 mg PO 4× day
Cetirizine hydrochloride tablet 10 mg PO daily (for allergies) Purchased over the counter	Methotrexate tablet 10 mg PO every Monday

- ☐ 1. Have the family give the child cetirizine daily using the medication they have from home.
- ☐ 2. Explain the need to limit over-the-counter medications while in the hospital.
- ☐ 3. Request a cetirizine prescription from the healthcare provider (HCP).
- ☐ 4. Contact the HCP to question the methotrexate.

65. A 4-year-old male presents to the emergency department. His father tearfully reports that his son was on his shoulders in the driveway playing when he began to fall. When the child began to fall, the father grabbed him by the leg, swinging him toward the grass to avoid landing on the pavement. As the father swung his son, the child hit his head on the driveway and twisted his right leg. After a complete examination, it is determined that the child has a skull fracture and a spiral fracture of the femur. Which action should the nurse take?

- ☐ 1. Restrict the father's visitation.
- ☐ 2. Notify the police immediately.
- ☐ 3. Refer the father for parenting classes.
- ☐ 4. Record the father's story in the medical record.

Answers, Rationales, and Test-Taking Strategies

*The answers and rationales for each question follow below, along with keys () to the client need (CN) and cognitive level (CL) for each question. In addition, you will also see a glossary icon () highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 10–21 and pages 31–32 in Part 1 of this book.*

The Client with Torticollis, Legg-Calvé-Perthes Disease, and Musculoskeletal Dysfunction

1. 2. Physical therapy is the most important part of the child's plan of care. Most cases of torticollis respond to gentle stretching exercises, which the parents perform daily. Regular physical therapy is needed to monitor the infant's progress. Botulinum toxin injections are not approved for children under the age of 2 and would not be an appropriate first-line treatment for an infant. Surgery is only done if physical therapy is not successful after several months. The use of wedges to position children during sleep is not recommended because they increase the risk of SIDS.

 CN: Management of care; CL: Create

2. 4. Legg-Calvé-Perthes disease, also known as *coxa plana* or *osteochondrosis*, is characterized by aseptic necrosis at the head of the femur when the blood supply to the area is interrupted. Avoidance of weight bearing is especially important to prevent the head of the femur from leaving the acetabulum, thus preventing hip dislocation. Devices such as an abduction

brace, a leg cast, or a harness sling are used to protect the affected joint while revascularization and bone healing occur. Surgical procedures are used in some cases. Although pain control measures may be appropriate, pain is not necessarily more acute at night. Initial therapy involves rest and non-weight bearing to help restore motion. Preventing flexion is not necessary.

CN: Physiological adaptation; CL: Create

3. 3. Because most of the child's care takes place at home, the primary focus of family teaching would be on the care and management of the corrective device. Devices such as an abduction brace, a leg cast, or a harness sling are used to protect the affected joint while revascularization and bone healing occur. As long as the child is eating a well-balanced diet, there is no need for an intake of protein-rich foods. The parents can encourage range of motion in the unaffected leg, but motion in the affected leg is limited until it heals. Once therapy has been initiated, pain is usually not a problem. The key is management of the corrective device.

CN: Reduction of risk potential; CL: Create

4. 4. The parent is describing symptoms consistent with torticollis, or wry neck syndrome. With this musculoskeletal disorder, the sternocleidomastoid muscle shortens, causing the infant to drop the head toward the affected muscle and tilt the chin upward in the opposite direction. Frequently, a lump may be felt in the affected muscle. Palpating the fontanelle is done to assess neurologic status, not musculoskeletal status. Torticollis does not involve the cervical vertebrae or trapezius muscle.

CN: Physiological adaptation; CL: Analyze

5. 1. The adolescent's problem should alert the nurse to the possibility of Osgood-Schlatter disease. This disease, found primarily in boys 10 to 15 years of age and in girls 8 to 13 years of age, occurs when the infrapatellar ligament of the quadriceps muscle is not well anchored to the tibial tubercle. Excessive activity of the quadriceps muscle results in microtrauma, which causes swelling and pain. Track, soccer, and football commonly produce this condition. Osgood-Schlatter disease is self-limited and usually responds to rest and application of ice.

CN: Physiological adaptation; CL: Analyze

6. 4. The adolescent is most likely experiencing heat exhaustion or heat collapse, which are common after vigorous exercise in a hot environment. Symptoms result from loss of fluids and include nausea, vomiting, dizziness, headache, and thirst. Treatment consists of moving the adolescent to a cool environment and giving cool liquids. Cool liquids are easier to drink than are cold liquids. Taking the adolescent's temperature would be appropriate once these actions have been completed. However, the adolescent's temperature is likely to be normal or only mildly elevated. Lying in the supine position increases the risk for aspiration if vomiting occurs in a client with nausea.

CN: Basic care and comfort; CL: Synthesize

The Client with Cerebral Palsy

7. 3. It is important to identify primary developmental delays in children with cerebral palsy and to prevent secondary and tertiary delays. The arrested development is worrisome and requires further investigation. It is possible the lack of development indicates hearing loss or may be a sign of autism. The brain damage caused by cerebral palsy is not progressive. The brain of a young child is quite plastic; assuming the child's development has peaked at age 3 would be a serious mistake. The therapy plan will need to be modified, but a better understanding of the underlying problem will lead to the greatest chance of creating a successful therapy plan.

CN: Health promotion and maintenance; CL: Synthesize

8. 2,3,4,5. Botulinum toxin injections can be used to improve many aspects of quality of life for the child with cerebral palsy. The injections can help decrease pain from spasticity. Injections improve motor status by reducing rigidity and allowing for more effective physical therapy to improve range of motion. Decreased spasms enhance self-esteem. Improved motor status facilitates the ability to provide some aspects of care, especially transfers. Botulinum does not significantly affect nutritional status or speech.

CN: Management of care; CL: Create

9. 3. The term *cerebral palsy* (CP) refers to a group of nonprogressive disorders of upper motor neuron impairment that result in motor dysfunction due to injury. In addition, a child may have speech or ocular difficulties,

seizures, hyperactivity, or cognitive impairment. The condition of congenital malformed blood vessels in the ventricles is known as arteriovenous malformations. Viral infection and metabolic imbalances do not cause CP.

CN: Physiological adaptation; CL: Evaluate

10. 4. Delay in achieving developmental milestones is a characteristic of children with cerebral palsy. Ninety percent of typically developing 15-month-old children can put a block in a cup. Walking up steps typically is accomplished at 18 to 24 months. A child usually is able to use a spoon at 18 months. The ability to copy a circle is achieved at approximately 3 to 4 years of age.

CN: Health promotion and maintenance; CL: Analyze

11. 3. The parent is the child's **HCP**  and may be very in tune to subtle changes in the child's behavior. If the parent thinks the child is in pain, it is very likely to be so. The nurse should administer the pain medication and evaluate if the medication affected the child's behavior. The FLACC scale may be difficult to interpret when the child has spasticity. The FACES scale requires self-report, which may not be possible in a child with a communication disorder. The HCP should be contacted regarding the change in behavior only if other available interventions are unsuccessful.

CN: Basic care and comfort; CL: Synthesize

12. 3. The nurse needs to respond honestly to the mother. Most children with hemiparesis due to spastic cerebral palsy are able to walk because the motor deficit is usually greater in the upper extremity. There is no need to refer the mother to the **HCP** . Pulling to a stand requires both upper body and lower body strength. The will to walk is important, but without neurologic stability, the child may be unable to do so.

CN: Physiological adaptation; CL: Synthesize

13. 1. Limited interaction or lack of interaction with friends and family may lead the nurse to suspect a possible problem with the family's ability to cope with others' reactions and responses to a child with cerebral palsy. Learning measures to meet the child's physical needs demonstrates some understanding and acceptance of the disease. Requesting teaching about the

disease suggests curiosity or a desire for understanding, thus demonstrating that the family is dealing with the situation. Participating in social media may serve as a form of support and can be a healthy coping mechanism.

CN: Psychosocial integrity; CL: Evaluate

The Client with Duchenne's Muscular Dystrophy

14. 1. Duchenne's muscular dystrophy is an X-linked recessive disorder. The gene is transmitted through female carriers to affected sons 50% of the time. Daughters have a 50% chance of being carriers.

CN: Physiological adaptation; CL: Apply

15. 3. Usually, the first clinical manifestations of Duchenne's muscular dystrophy include difficulty with typical age-appropriate physical activities such as running, riding a tricycle, and climbing stairs. Contractures of the large joints typically occur much later in the disease process. Occasionally, enlarged calves may be noted, but they are not typical findings in a child with Duchenne's muscular dystrophy. Muscular atrophy and development of small, weak muscles are later signs.

CN: Physiological adaptation; CL: Analyze

16. 4. With Gower's sign, the child walks the hands up the legs in an attempt to stand, a common approach used by children with Duchenne's muscular dystrophy when rising from a sitting to a standing position. Galeazzi's sign refers to the shortening of the affected limb in congenital hip dislocation. Goodell's sign refers to the softening of the cervix, considered a sign of probable pregnancy. Goodenough's sign refers to a test of mental age.

CN: Physiological adaptation; CL: Analyze

17. 3. The primary nursing goal is to maintain function in unaffected muscles for as long as possible. There is no effective treatment for childhood muscular dystrophy. Children who remain active are able to forestall being confined in wheelchair. Remaining active also minimizes the risk for social isolation. Preventing rather than encouraging wheelchair use by maintaining function for as long as possible is an appropriate nursing goal. Children with muscular dystrophy become socially isolated as their condition deteriorates

and they can no longer keep up with friends. Maintaining function helps prevent social isolation. Circulatory impairment is not associated with muscular dystrophy.

CN: Physiological adaptation; CL: Create

18. 3. The guilt that mothers of children with muscular dystrophy commonly experience usually results from the fact that the disease is genetic and the mother transmitted the defective gene. Although many children die from the disease, the disease is considered chronic and progressive. As the disease progresses, the child becomes more dependent. However, guilt typically stems from the knowledge that the mother transmitted the disease to her son rather than the dependency of the child. The disease onset is usually gradual, not sudden.

CN: Psychosocial integrity; CL: Analyze

19. 1. Muscular dystrophy is a progressive disease. Children who are affected by this disease usually are unable to walk independently by age 9 to 11 years. There is no effective treatment for childhood muscular dystrophy. Although children who remain active are able to avoid wheelchair confinement for a longer period, activity does not prevent disease progression.

CN: Physiological adaptation; CL: Evaluate

The Client with Developmental Dysplasia of the Hip

20. 4. A Trendelenburg's sign is seen in children with developmental dysplasia of the hip who are walking. Weight bearing causes the pelvis to tilt downward on the unaffected side instead of upward as it would normally. Ortolani's maneuver is used during the neonatal period to assess developmental dysplasia of the hip in infants. With the infant quiet, relaxed, and lying on the back, the hips and knees are flexed at right angles. The knees are moved to abduction, and pressure is exerted. If the femoral head moves forward, then it is dislocated. Barlow's maneuver is used to assess developmental dysplasia of the hip in infants. As the femur is moved into or out of the acetabulum, a "clunk" is heard, indicating dislocation. Adam's position is used to evaluate for structural scoliosis. The child bends forward

with feet together and arms hanging freely or with palms together.

CN: Reduction of risk potential; CL: Analyze

21. 4. This infant with congenital hip dysplasia has asymmetric gluteal folds. The Ortolani's "click" occurs when the nurse feels the femur sliding into the acetabulum with a "click." Limited abduction may be observed during an attempt to abduct the infant's thighs. Galeazzi's sign reveals femoral foreshortening and is observed by flexing the thighs.

CN: Health promotion and maintenance; CL: Analyze

22. 1. The Pavlik harness is worn over a diaper. Knee socks are also worn to prevent the straps and foot and leg pieces from rubbing directly on the skin. For maximum results, the infant needs to wear the harness continuously. The skin should be inspected several times a day, not every other day, for signs of redness or irritation. Lotions and powders are to be avoided because they can cake and irritate the skin.

CN: Reduction of risk potential; CL: Synthesize

23. 2. Assessing the learner's knowledge level is the initial step in any teaching plan to promote the maximum amount of learning. This assessment also provides the nurse with a starting point for teaching. Assessing coping strategies can provide important information to the development of the teaching plan but is not the initial step. Giving parents written instructions or a list of community resources is appropriate once the parents' knowledge level has been determined and teaching has begun.

CN: Reduction of risk potential; CL: Create

24. 3. The abduction bar is incorporated into the cast to increase the cast's strength and maintain the legs in alignment. The bar cannot be removed or adjusted, unless the cast is removed and a new cast is applied. The bar should never be used to lift or turn the client because doing so may weaken the cast.

CN: Reduction of risk potential; CL: Synthesize

25. 2. The toddler in a hip spica cast needs a specially designed car seat. The one that the mother already has will not be appropriate because of the need for the car seat to accommodate the cast and abductor bar.

CN: Safety and infection control; CL: Synthesize

The Client with Congenital Clubfoot

26. 2. Elevating the extremity at different points during the day is helpful to prevent edema, but pillows should not be used in the crib because they increase the risk of sudden infant death syndrome (SIDS). A change in the color of the toes is a sign of impaired circulation and requires medical evaluation. Children typically need a series of 5 to 10 casts to correct the deformity. Infants with clubfeet still need frequent holding like any other newborn.

CN: Safety and infection control; CL: Evaluate

27. 3. When an infant is born with an unexpected anomaly, parents are faced with questions, uncertainties, and possible disappointments. They may feel inadequate, helpless, and anxious. The nurse can help the parents initially by assessing their concerns and providing appropriate information to help them clarify or resolve the immediate problems. Referring the parents to the **healthcare provider (HCP)** 📖 is not necessary at this time. The nurse can assist the parents by listening to their concerns. Having them talk with other parents would be helpful a little bit later, once the nurse assesses their concerns and discusses the problem and the parents' current feelings. If the parents continue to have difficulties expressing and working through their feelings, referral to a counselor would be appropriate.

CN: Psychosocial integrity; CL: Synthesize

28. 3. A cast that is too tight can cause a tourniquet effect, compromising the neurovascular integrity of the extremity. Manifestations of neurovascular impairment include pain, edema, pulselessness, coolness, altered sensation, and inability to move the distal exposed extremity. The toes of the casted extremity should be assessed frequently to evaluate for changes in neurovascular integrity. Wetting a plaster cast with water and soap softens the plaster, which may alter the cast's effectiveness. There is no reason to elevate the casted extremities when a child with clubfoot is being treated with nonsurgical measures. The legs would be elevated if swelling were present. Petals, which are applied to cover the rough edges of the cast, are to be left in

place to minimize the risk for skin irritation from the cast edges.

CN: Reduction of risk potential; CL: Evaluate

The Client with Juvenile Idiopathic Arthritis

29. 4. The nurse's response to the father is based on the knowledge that there is no definitive test for JIA. The latex fixation test, which is commonly used to diagnose arthritis in adults, is negative in 90% of children. The erythrocyte sedimentation rate may or may not be increased during active disease. This test identifies the presence of inflammation only. Synovial fluid cultures are done to rule out septic arthritis, not to diagnose JIA.

CN: Reduction of risk potential; CL: Analyze

30. 1. With JIA, the more joints affected, the more severe the disease is likely to be and the less likely the symptoms will totally resolve. Approximately one-third of the children will continue to have the disease into adulthood, and approximately one-sixth will experience severe, crippling deformities.

CN: Physiological adaptation; CL: Apply

31. 2. Socialization is important for this preschool-age child, and activity is important to maintain function. Because children with JIA commonly experience most problems in the early morning after arising, they need more time to “warm up.” Adverse effects may or may not occur. The child's normal routine needs to be maintained as much as possible. Although splints and braces may be needed, they are worn during periods of rest, not activity, to maintain function.

CN: Physiological adaptation; CL: Synthesize

32. 4. Because the child is dealing with grief and loss associated with a chronic illness, parents need to be supportive and understanding. The child needs to feel valued and worthwhile. Introducing the child to others of the same age who also have JIA most probably would be ineffective because preschoolers are developmentally egocentric. Although the child needs to feel valued, the mother's spending more time with the child and less time with her other children is inappropriate because the child with JIA may experience

secondary gain from the illness if the family interaction patterns are altered. Also, this action reinforces the child's withdrawal behavior. Psychological counseling is not needed at this time because the child's reaction is normal.

CN: Psychosocial integrity; CL: Synthesize

33. 2,3,5. Adverse effects from nonsteroidal anti-inflammatory drugs include abdominal pain, blood in stool, and reduced clotting ability. Weight gain is common with corticosteroids. Folic acid deficiency is associated with methotrexate therapy.

CN: Pharmacological and parenteral therapies; CL: Apply

34. 3. The first group of drugs typically prescribed is the nonsteroidal anti-inflammatory drugs, which include naproxen. Once therapy is started, it takes hours or days for relief from pain to occur. However, it takes 3 to 4 weeks for the anti-inflammatory effects to occur, including reduction in swelling and less pain with movement. Naproxen is included in only a few over-the-counter medications, but aspirin is in several. The family should check with the nurse before giving any over-the-counter medications. Toxicity or GI bleeding may occur when nonsteroidal anti-inflammatory drugs are combined. The missed dose will need to be made up to maintain the serum level and to maintain therapeutic effectiveness of the drug.

CN: Pharmacological and parenteral therapies; CL: Apply

The Client with a Fracture

35. 2,3,4,5. Buck's traction provides a skin traction that keeps the extremity in straight alignment and can be observed by noting a straight line formed between the shoulder, hips, and knees. The rope must be intact to maintain the prescribed traction from the weights. The correct amount of traction must be maintained to keep the fractured femur in correct alignment. Because the client is in a recumbent position, the nurse should also inspect the skin on the back and buttocks for integrity. The nurse should not remove the client's wraps and boot unless he or she has a **healthcare provider's (HCP's)** prescription to do so.

CN: Physiological adaptation; CL: Analyze

36. 3. The wet plaster cast should be handled using only the palms of the hands to prevent indentations of the cast surface. Petaling a cast should be done only when the edges of the cast are rough and are causing irritation to the client's skin. The nurse should not keep the child in the same position until the cast is dry. Doing so would prohibit proper toileting and elimination and would produce undue pressure on the coccyx. The cast typically emits heat as it dries, so notifying a **healthcare provider (HCP)** 📖 is not necessary in this instance. If needed, a fan can be used to circulate the room air.

🔑 CN: Health promotion and maintenance; CL: Evaluate

37. 3. The nurse should show the parents the figure of the greenstick fracture as noted in answer 3 in which the fracture does not completely cross through the bone. Answer A is a plastic deformation, or a bend in the bone. Answer B is a buckle. Answer D is a complete fracture.

🔑 CN: Physiological adaptation; CL: Synthesize

38. 2. Emotional or physical stress lowers a person's tolerance of pain. The parent's presence may have distracted him, and when the parent left, it caused him to focus on the pain he was having. Crying does not automatically indicate pain. The nurse must further assess the client for pain. Although an analgesic was given 4 hours before, pain may be present.

🔑 CN: Physiological adaptation; CL: Analyze

39. 2. As part of a surgery safety checklist, the nurse must verify that the site, side, and level are marked. Pointing to the area is not sufficient identification of the surgery site. The nurse must verify the form has been signed by reviewing the form. The surgeon holds primary responsibility for explaining the risks of surgery.

 CN: Safety and infection control; CL: Synthesize

40. 1. Skeletal traction applies the pull directly to the skeletal structure by tongs, pin, or wire. The nurse should assess the pull of the traction on the pin first. This is critical to the success of the traction. Once this is assessed, then the pin sites are assessed for signs of infection. The dressings would be examined after the pull of the traction, neurovascular status, and pin sites were assessed. The Ace wrap is used to anchor skin traction nonadherent straps, not skeletal traction.

 CN: Reduction of risk potential; CL: Synthesize

41. 2. The traction is positioned correctly; the nurse should provide frequent skin care to the back and shoulder areas. The hips and buttocks should be lifted off the bed to provide countertraction; the nurse should not adjust the weights. The nurse should not place a pillow under the buttocks as this would prevent countertraction. The elastic wraps should remain on the legs unless removal is prescribed by the **healthcare provider (HCP)** .

 CN: Physiological adaptation; CL: Synthesize

42. 3. The nurse should assess the client frequently for signs of neurovascular impairment of the feet, such as pallor, coldness, numbness, or tingling. Pillows are not placed under the buttocks because the pillows would alter the alignment of the traction. Weights provide traction and should not be removed. Pulleys help to maintain optimal alignment of the traction and therefore should be left alone.

 CN: Basic care and comfort; CL: Synthesize

43. 3. Explaining to the parents that this is a normal reaction under the circumstances is most appropriate. The child's outburst is related to the child's fears of the unknown. The child is scared and anxious and needs the parents for support. Asking the parents to wait outside would only add to the child's fear and anxiety. The reaction is normal for a child her age and does not usually call for a change in staff assignments. Asking the parents to discipline their child for her behavior is inappropriate. The nurse needs to handle the situation.

 CN: Health promotion and maintenance; CL: Synthesize

44. 1. Inability to extend the fingers of the involved arm may indicate neurologic impairment caused by pressure on soft tissue. It is not unusual for a child to vomit after experiencing a traumatic injury. It may take up to 72 hours for a plaster cast to dry. Until the cast dries, the dampness causes the sensation of coolness. The cast will seem heavy until the child adjusts to the extra weight. The child may exhibit fussiness (such as whining, crying, or clinging) as a result of numerous causes, such as placement of the cast, the hospital experience, or pain. These reactions are normal and do not warrant medical advice.

CN: Reduction of risk potential; CL: Evaluate

45. 2. For the first few days after application of a plaster or fiberglass cast, the child should not engage in strenuous activities, to minimize swelling that would cause the cast to become too tight. Use of a hair dryer to complete the drying of the cast is not encouraged because the hair dryer only dries the outside of the cast. Movement and sensation of the fingers need to be checked several times a day for the first few days. Typically, the parent would be instructed to administer acetaminophen every 4 to 6 hours, not every 8 to 12 hours, for discomfort.

CN: Reduction of risk potential; CL: Synthesize

46. 1. Because the nurse suspects a possible fracture based on the child's presentation, assessing the neurologic and circulatory status of the toes, the tissues distal to the fracture, is important. Soft tissue contusions, which accompany femur fractures, can result in severe hemorrhage into the tissue and subsequent circulatory and neurologic impairment. Once this information has been obtained, vital signs can be assessed, and the nurse can notify the **healthcare provider (HCP)**  and report the findings. In fractures, circulation impairment will occur distal to the injury.

CN: Physiological adaptation; CL: Synthesize

47. 3. Hand puppets would enable a 3-year-old child in traction to act out feelings within the constraints imposed by the traction. A 3-year-old needs creative play. The video game would make the child too active in bed and does not meet the child's developmental need for creative play. Blocks would be more appropriate for a younger child. Remote-controlled cars are

appropriate for older children but can present a fall risk to others if used in a hospital.

CN: Health promotion and maintenance; CL: Synthesize

48. 2. Stressing the importance of the parents' visiting when they can helps to alleviate the guilt they feel. It allows the parents to feel that they are doing what they can. Acknowledging the guilt gives the parents an opportunity to talk about it but does not help alleviate it. Comparing the parents with other parents does not alleviate guilt feelings. The parents need reinforcement that what they are doing is appropriate. Suggesting that the parents take turns visiting implies that they should feel guilty because they may not be doing all they could.

CN: Psychosocial integrity; CL: Synthesize

49. 2. A hip spica cast encircles the abdomen. When the child eats a large meal, abdominal pressure increases, causing the cast to feel tight. Therefore, the nurse should plan to offer smaller, more frequent meals to minimize abdominal distention. If the child's appetite were decreased in conjunction with a feeling of fullness, the nurse might suspect that the child was becoming constipated and plan to use laxatives or a higher-fiber diet. A mechanical soft diet is indicated when the child has difficulty chewing food adequately. Giving the child more fruits and grains would contribute to abdominal distention and problems with the cast tightness after eating.

CN: Reduction of risk potential; CL: Synthesize

50. 2. The child with a hip spica cast who is going home and has a bedroom on the second floor of the home needs to have the bed moved to an area that is more central to family life. Negotiating a flight of steps at least twice a day (on awakening in the morning and before going to bed at night) with a child in a hip spica cast would be difficult and most likely dangerous. Because the child in a hip spica cast will need to use a bedpan or urinal, the bathrooms can be on any floor. Because the family is involved in the discharge, the 16-year-old sister should be taught appropriate care along with the rest of the family. The child can be carried up and down the three steps to the house the few times necessary after discharge.

CN: Safety and infection control; CL: Create

51. 2,3. To ensure proper fit of crutches, the child's elbow flexion should be 20 degrees, and the area above the top of the crutch to the child's axilla should be 1 to 1½ inches (2.5 to 3.8 cm). The type of gait, weight of the child, and use of stairs are not factors in the measurement.

CN: Reduction of risk potential; CL: Apply

The Client with Osteomyelitis

52. 3. Findings associated with osteomyelitis commonly include pain over the area, increased warmth, localized tenderness, and diffuse swelling over the involved bone. The area over the affected bone is red.

CN: Physiological adaptation; CL: Analyze

53. 2. Cultures are used to determine exactly what organism is causing the inflammation. From the culture, sensitivities to various antibiotics may be determined. If the antibiotics are given before obtaining the culture, the antibiotics may inhibit the growth of the organism in the culture medium. This may lead to a delay in the most appropriate treatment. Unless a child has a known renal problem, baseline creatinine levels are not typically needed. However, levels may be needed during treatment depending on the medication. A complete blood count (CBC) with hemoglobin and white blood cell count is typically prescribed for any suspected infection, but these tests do not identify the causative organism.

CN: Reduction of risk potential; CL: Apply

54. 3. The vancomycin level is not therapeutic and will need to be adjusted. Drug management by the pharmacy is prescribed. Thus, the nurse should notify the pharmacist to adjust the dose. This is very frequently done in institutions with pediatric clinical pharmacists. Giving subtherapeutic doses may prolong care. If needed, the pharmacist would notify the care provider. Peak levels are not prescribed on this client.

CN: Pharmacological and parenteral therapies; CL: Synthesize

55. 4. Long-term, high-dose antibiotic therapy can adversely affect renal, hepatic, and hematopoietic function. Urine specific gravity would provide valuable information about the kidneys' ability to concentrate or dilute urine,

thereby suggesting renal impairment. Blood glucose levels reveal how well the client's body is using glucose. Thrombin times reveal information about the clotting mechanism. Urine glucose levels reveal information about the body's use and excretion of glucose.

CN: Pharmacological and parenteral therapies; CL: Analyze

56. 1. Encouraging contact with schoolmates allows the school-age child to maintain and develop socialization with peers, an important developmental task of this age group. Although having family visits and interacting with the child are important, they do not meet the child's developmental needs. Talking to the child about his interests is important, but encouraging contact with schoolmates is crucial to maintain and develop socialization with peers.

CN: Health promotion and maintenance; CL: Create

57. 1. Some clients find ginger cookies or “snaps” help relieve nausea. Ginger, in small doses such as would be found in the cookies, has few side effects. There is no reason that the parent should not try this dietary intervention; however, the nurse must monitor the client's response. If the child has a diet as tolerated prescription, there is no need for an additional prescription. Ultimately, the child may need an antiemetic medication, but dietary strategies are often successful in treating vomiting related to osteomyelitis. Making a universal statement disregarding home remedies is not a client-centered approach.

CN: Physiological adaptation; CL: Synthesize

The Client with Scoliosis

58. 1. Scoliosis, a lateral deviation of the spine, is assessed by having the client bend forward at the waist with arms hanging freely and then looking for lateral curvature of the spine and a rib hump. The other positions will not reveal the deviation of the spine.

CN: Health promotion and maintenance; CL: Analyze

59. 1. One of the most effective spinal braces for correcting scoliosis, the Boston brace should be worn for at least 16 to 23 hours a day, except when carrying out personal hygiene measures.

 CN: Reduction of risk potential; CL: Evaluate

60. 4. Exercises are prescribed for the child with scoliosis wearing a Boston brace to help strengthen spinal and abdominal muscles and provide support. Typically, children wearing a Boston brace do not have muscle spasms. Performing exercises provides no effect on the brace's traction ability. Spinal contractures do not occur when a Boston brace is worn.

 CN: Physiological adaptation; CL: Apply

61. 3. A form-fitting t-shirt can be worn under the brace to prevent skin irritation and collect perspiration. Braces are worn 23 hours each day. Lotions may cause irritation and should not be used. The skin under the brace should be bathed daily to help prevent irritation from the brace. The brace can be removed for bathing so all the skin can be bathed.

 CN: Physiological adaptation; CL: Create

Managing Care, Quality, and Safety of Children with Musculoskeletal Health Problems

62. 2. To prevent a baclofen withdrawal, pump refills are scheduled several days before anticipated low-volume alarms. The nurse should make it a high priority to have the pump refilled as soon as possible. Discontinuing baclofen suddenly can result in a high fever, muscle rigidity, change in level of consciousness, and even death. Waiting until the child leaves the hospital for a refill may lead to a low dose or withdrawal. Waiting for the low-volume alarm puts the client at risk because medication and team members who can refill the pump may not be readily available under all circumstances.

 CN: Management of care; CL: Synthesize

63. 2,3. In general, LPN/VNs  may perform skills related to feeding, oral medication administration, and activities of daily living, such as insertion of a hearing aid. Refilling a baclofen pump constitutes administering an intrathecal medication and is beyond the scope of practice for LPN/VNs in most areas. Some institutions allow LPN/VNs to give IV push medicines; however, special training is required. Communicating with the **healthcare provider (HCP)**  would require discussion of the client's assessments and

evaluations, which fall under the RN scope of practice.

CN: Management of care; CL: Synthesize

64. 3. If the child was taking cetirizine for allergies, the nurse should contact the **HCP**  for a prescription to continue the medication in the hospital. The provider should either prescribe the medication or provide a valid reason to discontinue its use. Advising the family to take a home supply of medications increases the risk of adverse reactions because the provider would be unaware of potential medication interactions. Many allergy medications that formerly required a prescription are now available over the counter, and because parents use them, the nurse should be aware of the interactions and risks. The nurse does not need to question the methotrexate prescription as this medication is being added to treat the JIA.

CN: Safety and infection control; CL: Synthesize

65. 4. The father's story is consistent with the injuries incurred by the child; therefore, the nurse should document the cause of injury. There is no need to restrict the father's visitation because the injuries sustained by the child are consistent with the explanation given. The police only need to be notified if there is suspicion of child abuse. The injuries incurred by this child appear to be accidental. There is no need to refer the father for parenting classes. The father appears to be upset about the accident and will not likely repeat such reckless behavior. However, the nurse should educate the father regarding child safety.

CN: Management of care; CL: Analyze

The Child with Dermatologic and Endocrine Health Problems

- The Client with Skin Disorders
- The Client with Burns
- The Client with a Thyroid Problem
- The Client with Insulin-Dependent Diabetes Mellitus
- The Client with Polycystic Ovarian Syndrome
- Managing Care, Quality, and Safety of Children with Dermatologic and Endocrine Health Problems
- Answers, Rationales, and Test-Taking Strategies

The Client with Skin Disorders

1. A 17-year-old female with severe nodular acne is considering treatment with isotretinoin. Prior to beginning the medication, the nurse explains that the client will be required to:

- ☐ **1.** enroll in a risk management plan.
- ☐ **2.** have proof of a mental health evaluation.
- ☐ **3.** begin an effective form of birth control when starting the medication.
- ☐ **4.** temporarily give up sports.

2. When teaching an adolescent with facial acne about skin care, the nurse should instruct the adolescent to:

- ☐ **1.** wash the face twice a day with mild soap and water.
- ☐ **2.** remove whiteheads and comedones after washing the face with antibacterial soap.
- ☐ **3.** apply vitamin E ointment twice daily to the affected skin.

- ☐ 4. apply tretinoin daily in the morning and expose the face to the sun.

3. A 9-month-old infant with eczema has lesions that are secondarily infected. Which recommendation is the **most** appropriate to help the parents best meet the needs of the child?

- ☐ 1. Prevent siblings from being in close contact.
- ☐ 2. Send the child to day care as usual.
- ☐ 3. Play video games for several hours each evening.
- ☐ 4. Play with the child every day.

4. After the nurse teaches the mother of a child with atopic dermatitis how to bathe her child, which statement by the mother indicates effective teaching?

- ☐ 1. "I let my child play in the tub for 30 minutes every night."
- ☐ 2. "My child loves the bubble bath I put in the tub."
- ☐ 3. "When my child gets out of the tub I just pat the skin dry."
- ☐ 4. "I make sure my child has a bath every night."

5. A 5-year-old child brought to the clinic with several superficial sores on the front of the left leg is diagnosed with impetigo. Which instructions should the nurse give the parent?

- ☐ 1. Wash the child's legs once a day with a mild soap.
- ☐ 2. Cover the sores with loose gauze.
- ☐ 3. Allow the child to go back to school after 24 hours of treatment.
- ☐ 4. Have the child return to the clinic the next week for a follow-up examination.

6. When developing the teaching plan for the mother of a 2-year-old child diagnosed with scabies, what information should the nurse expect to include?

- ☐ 1. The floors of the house should be cleaned with a damp mop.
- ☐ 2. The child should be held frequently.
- ☐ 3. Itching should cease in a few days.
- ☐ 4. The entire family should be treated.

The Client with Burns

7. A 10-year-old has just spilled hot liquid on his arm, and a 4-inch (10-cm) area on his forearm is severely burned. His mother calls the emergency department. What should the nurse advise the mother to do?

- ☐ 1. Keep the child warm.
- ☐ 2. Cover the burned area with an antibiotic cream.
- ☐ 3. Apply cool water to the burned area.
- ☐ 4. Call 911 to transport the child to the hospital.

8. A school-age child who has received burns over 60% of his body is to receive 2,000 mL of IV fluid over the next 8 hours. At what rate (in milliliters per hour) should the nurse set the infusion pump? Round your answer to a whole number.

_____ mL/h.

9. Which interventions would be **most** appropriate to institute when a school-age child with burns becomes angry and combative when it is time to change the dressings and apply mafenide acetate?

- ☐ 1. Ensure parental support during the dressing changes.
- ☐ 2. Allow the child to assist in removing the dressings and applying the cream.
- ☐ 3. Give the child permission to cry during the procedure.
- ☐ 4. Allow the child to schedule the time for dressing changes.

10. A 5-year-old child with burns on the trunk and arms has no appetite. The nurse and the parent develop a plan of care to stimulate the child's appetite. Which suggestion made by the parent would indicate the need for additional teaching?

- ☐ 1. deciding that she will feed the child herself
- ☐ 2. withholding dessert and treats unless meals are eaten
- ☐ 3. offering the child finger foods that the child likes
- ☐ 4. serving smaller and more frequent meals

11. After teaching the parent of a child with severe burns about the importance of specific nutritional support in burn management, which selection of foods, if chosen by the parent from the child's diet menu, indicate the need for further instruction?

- ☐ 1. bacon, lettuce, and tomato sandwich; milk; and celery and carrot sticks
- ☐ 2. cheeseburger, cottage cheese and pineapple salad, chocolate milk, and a brownie
- ☐ 3. chicken nuggets, orange and grapefruit sections, and a vanilla milkshake
- ☐ 4. beef, bean, and cheese burrito; a banana; fruit-flavored yogurt; and skim milk

12. When caring for a child with moderate burns from the waist down, what should the nurse do when positioning the child?

- ☐ 1. Place the child in a position of comfort.
- ☐ 2. Allow the child to lie on the abdomen.
- ☐ 3. Ensure the application of leg splints.
- ☐ 4. Have the child flex the hips and knees.

The Client with a Thyroid Problem

13. An adolescent is to receive radioactive iodine for Graves' disease. Which statement by the client reflects the need for more teaching?

- ☐ 1. "I plan to talk on Facebook since I have to keep several feet (meters) from my friends for 3 days."
- ☐ 2. "Taking radioactive iodine will not affect my ability to have children in the future."
- ☐ 3. "The advantage of radioactive iodine is that I will not need future medication for my disease."
- ☐ 4. "I should try to use a separate bathroom from the rest of my family for several days."

14. Which clinical manifestations would lead the nurse to suspect that an infant has hypothyroidism? Select all that apply.

- ☐ 1. cool extremities
- ☐ 2. umbilical hernia
- ☐ 3. increased appetite
- ☐ 4. muscle weakness
- ☐ 5. lethargy

- ☐ 6. tachycardia

15. The nurse should instruct the family of a child with newly diagnosed hyperthyroidism to:

- ☐ 1. keep their home warmer than usual.
- ☐ 2. encourage plenty of outdoor activities.
- ☐ 3. promote interactions with one friend instead of groups.
- ☐ 4. limit bathing to prevent skin irritation.

16. An 11-year-old child has been diagnosed with Graves' disease and is to start drug therapy. Which instruction should the nurse include in the teaching plan for the child's parent and teacher?

- ☐ 1. Continue with the same amount of schoolwork and homework.
- ☐ 2. Understand that mood swings are rare with this disorder.
- ☐ 3. Limit the amount of food that is offered to the child.
- ☐ 4. Provide the child with a calm, nonstimulating environment.

The Client with Insulin-Dependent Diabetes Mellitus

17. A student with type 1 diabetes tells the nurse she is feeling light-headed. The student's blood sugar is 60 mg/dL (3.3 mmol/L). Using the 15-15 rule, the nurse should give:

- ☐ 1. 15 mL of juice and give another 15 mL in 15 minutes.
- ☐ 2. 15 g of carbohydrate and retest the blood sugar in 15 minutes.
- ☐ 3. 15 g of carbohydrate and 15 g of protein.
- ☐ 4. 15 oz of juice and retest in 15 minutes.

18. An overweight adolescent has been diagnosed with type 2 diabetes. To increase the client's self-efficacy to manage the disease, the nurse should:

- ☐ 1. provide the client with a written daily food and exercise plan.
- ☐ 2. discuss eliminating junk food in the home with the parents.
- ☐ 3. arrange for the school nurse to weigh the child weekly.
- ☐ 4. utilize a peer with type 2 diabetes to role model lifestyle changes.

19. After 6 months of treatment with diet and exercise, a 12-year-old with type 2 diabetes still has a fasting blood glucose level of 140 mg/dL (7.8

mmol/L). The healthcare provider (HCP) has decided to begin metformin. The adolescent asks how the medication works. The nurse should tell the client that the medicine decreases the glucose production and:

- ☐ 1. replaces natural insulin.
- ☐ 2. helps the body make more insulin.
- ☐ 3. increases insulin sensitivity.
- ☐ 4. decreases carbohydrate adsorption.

20. The nurse is evaluating a child's skills in self- administering insulin (see figure). The nurse should:

- ☐ 1. have the child use both hands on the syringe.
- ☐ 2. ask the child to place the needle at a 45-degree angle.
- ☐ 3. tell the child to use a site lower on her thigh.
- ☐ 4. remind the child to rotate sites.

21. A 14-year-old is using glargine and lispro to manage type 1 diabetes. The prescription for sliding scale lispro reads:

Lispro subcutaneous give units according to sliding scale:

Blood glucose: 70–150 mg/dL

(3.9–8.3 mmol/L) = 0 units

151–200 mg/dL (8.4 –11.1 mmol/L) = 1 unit

201–250 mg/dL (11.2 – 13.9 mmol/L) = 2 units

251–300 mg/dL (13.93 – 16.65 mmol/L) = 3 units

301–350 mg/dL (17 – 19.4 mmol/L) = 4 units

Call for Blood glucose > 350 (19.4 mmol/L)

In addition give 1 unit for every
15 g of carbohydrate.

The morning blood glucose is 202 mg/dL (11.2 mmol/L), and the client is going to eat two carbohydrate exchanges. The nurse has the client administer how many units of lispro?

_____ units. Round your answer to a whole number.

22. An 8-year-old with diabetes is placed on an intermediate-acting insulin and regular insulin before breakfast and before dinner. She will receive a snack of milk and cereal at bedtime. The snack will:

- ☐ 1. help her regain lost weight.
- ☐ 2. provide carbohydrates for immediate use.
- ☐ 3. prevent late night hypoglycemia.
- ☐ 4. help her stay on her diet.

23. A nurse is teaching an 8-year-old with diabetes and her parents about managing diabetes during illness. The nurse determines the parents understand the instruction when they indicate that when the child is ill they will provide:

- ☐ 1. more calories.
- ☐ 2. more insulin.
- ☐ 3. less insulin.
- ☐ 4. less protein and fat.

24. A nurse is assessing an 8-year-old with diabetes who is experiencing hyperglycemia. Which symptoms indicate that the hyperglycemia requires immediate intervention? Select all that apply.

- ☐ 1. weakness
- ☐ 2. thirst
- ☐ 3. shakiness
- ☐ 4. hunger
- ☐ 5. headache
- ☐ 6. dizziness

25. The nurse talks to an adolescent about how she can tell her friends about her new diagnosis of diabetes. Which behavior by the adolescent indicates that the adolescent has responded positively to the discussion?

- ☐ 1. She asks the nurse for material on diabetes for a school paper.
- ☐ 2. She introduces the nurse to her friends as “the one who taught me all about my diabetes.”
- ☐ 3. She says, “I will try to tell my friends, but they will probably quit hanging out with me.”
- ☐ 4. She asks her friends what they think about someone who has a lifelong illness.

26. An adolescent with insulin-dependent diabetes is being taught the importance of rotating the sites of insulin injections. The nurse should judge that the teaching was successful when the adolescent identifies which complication that can result from using the same site?

- ☐ 1. destruction of the fat tissue and poor absorption
- ☐ 2. destruction of nerves and painful neuritis
- ☐ 3. destruction of the tissue and too-rapid insulin uptake
- ☐ 4. development of resistance to insulin and need for increased amounts

The Client with Polycystic Ovarian Syndrome

27. A 16-year-old has been diagnosed with polycystic ovarian syndrome (PCOS). Which statement indicates the need for more teaching?

- ☐ 1. “High levels of male hormones contribute to my PCOS.”

- ☐ 2. “I am at risk for type 2 diabetes.”
- ☐ 3. “Maintaining a healthy weight is an important part of my treatment plan.”
- ☐ 4. “Untreated PCOS will make getting pregnant impossible.”

28. A 15-year-old female client suspects that she might have polycystic ovarian syndrome (PCOS). Which symptoms would be consistent with PCOS? Select all that apply.

- ☐ 1. primary amenorrhea
- ☐ 2. obesity
- ☐ 3. increased body hair
- ☐ 4. acne
- ☐ 5. darkened skin in body fold
- ☐ 6. enlarged breast

29. A 17-year-old with polycystic ovarian syndrome (PCOS) has been placed on metformin. The nurse determines the client needs more teaching about metformin if she states the medication helps achieve which outcome?

- ☐ 1. reduced androgen levels
- ☐ 2. normalization of the menstrual cycle
- ☐ 3. increased insulin levels
- ☐ 4. reduced blood glucose levels

30. A 16-year-old female with polycystic ovarian syndrome (PCOS) is extremely upset, saying, “I am so embarrassed by hair on my face. I just do not fit in.” Which intervention is **most** needed?

- ☐ 1. Refer the client to a hair removal specialist.
- ☐ 2. Screen the client for depression.
- ☐ 3. Provide more information on causes and treatment options.
- ☐ 4. Suggest the client join a support group.

Managing Care, Quality, and Safety of Children with Dermatologic and Endocrine Health Problems

31. The parent of a 17-year-old boy, who is hospitalized for complications related to type I diabetes, requests to review the adolescent’s medical record.

The client reported receiving mental health counseling during the admission history but did not want his parent to know. The nurse is uncertain of how to protect the adolescent's privacy and accommodate the parent's request. Who is the **most** appropriate person to consult?

- ☐ 1. the unit nurse manager
- ☐ 2. the health care provider (HCP)
- ☐ 3. the organization's privacy officer
- ☐ 4. the customer service representative

32. The charge nurse on the pediatric floor has assigned a 6-year-old girl with newly diagnosed type 1 diabetes and an 8-year-old girl recovering from ketoacidosis to the same semiprivate room. The 6-year-old's mother is upset because the parent staying with the other child is male and believes the arrangement violates her social norms. The nurse should:

- ☐ 1. explain to the parents that this room arrangement facilitates teaching.
- ☐ 2. reassign the children to different rooms.
- ☐ 3. offer the parent another place to sleep.
- ☐ 4. refer the parent to the customer service representative.

33. A 7-year-old client with type 1 diabetes is sick with the flu. What is the **most** important information for the nurse to convey regarding diabetes management during illness?

- ☐ 1. Blood glucose needs to be checked more frequently during illness.
- ☐ 2. Children require less insulin when they are sick with the flu.
- ☐ 3. Urine ketones should be checked every other day during illness.
- ☐ 4. Increase intake of fluids high in carbohydrate to prevent diarrhea.

34. Which nursing intervention should be done **first** when managing a pediatric client admitted to the emergency department with severe diabetic ketoacidosis (DKA)?

- ☐ 1. Begin an insulin drip to lower the client's blood glucose level.
- ☐ 2. Correct any fluid deficit using an isotonic saline solution.
- ☐ 3. Draw a blood glucose level and serum electrolyte panel.
- ☐ 4. Secure the client's airway to ensure adequate ventilation.

35. The mother of an 8-year-old with diabetes tells the nurse that she does

not want the school to know about her daughter's condition. The nurse should reply:

- ☐ 1. "Your daughter will most likely tell her teacher even if you do not."
- ☐ 2. "What is it that concerns you about having the school know about your daughter's condition?"
- ☐ 3. "It would be fine not to tell your daughter's friends, but the teacher must know."
- ☐ 4. "In order to keep your daughter safe, it is necessary for all adults in the school to know her condition."

Answers, Rationales, and Test-Taking Strategies

*The answers and rationales for each question follow below, along with keys () to the client need (CN) and cognitive level (CL) for each question. In addition, you will also see a glossary icon () highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 12–23 and pages 35–36 in Part 1 of this book.*

The Client with Skin Disorders

1. 1. Because of the risk of birth defects with isotretinoin, risk management plans require all clients to meet certain requirements to obtain the medication. Providers are advised to closely monitor clients for signs of depression, but a mental health evaluation is not universally required. It is not sufficient to begin a single form of birth control after starting the medication. Women of childbearing age must use two forms of effective birth control for 2 months before, during, and 1 month after taking the drug. Isotretinoin may cause muscle aches, and extreme exercise should be avoided, but general participation in sports should be considered on an individual basis.

 CN: Safety and infection control; CL: Synthesize

2. 1. Washing the face once or twice a day with a mild soap removes fatty acids from the skin. Acne is an inflammation of the sebaceous glands that produce sebum. Washing the face with mild soap and water keeps the sebaceous glands from becoming plugged. Excessive washing or squeezing the eruptions can cause rupture of these glands, spreading the sebum and causing further inflammation. Applying vitamin E to the lesions does not reduce the inflammation and, due to the greasiness of the preparation, may plug the ducts. Isotretinoin should be applied at night. Exposure to the sun can result in sunburn and an increased risk of skin cancer and should be avoided. Sunscreen with a sun protection factor of at least 15 must be applied before the client can be exposed to the sun.

CN: Physiological adaptation; CL: Synthesize

3. 4. The parents can best meet the needs of their 9-month-old infant by playing with the child every day. All infants need time with their parents to develop trust and thus attain optimal development. The parents of a child with a chronic problem may need more guidance to meet the child's needs because of the focus on medical problems. The child's lesions are secondarily infected and therefore should not be contagious. Siblings do not need to stay away. Even with lesions that are infected, the child can still attend day care, but the child needs attention from the parents as well. Playing video games for several hours is not appropriate for a 9-month-old infant.

CN: Health promotion and maintenance; CL: Synthesize

4. 3. Atopic dermatitis is a chronic pruritic dermatitis that usually begins in infancy. Many of the children diagnosed with it have a family history of eczema, allergies, or asthma. Atopic dermatitis is best treated with hydrating the skin, controlling the pruritus, and preventing secondary infection. Patting the skin dry removes less natural skin moisturizer and thus maintains skin hydration. Playing in the tub for 30 minutes each night would deplete the skin of its natural moisturizers, thereby leading to increased pruritus and dry skin. Bubble baths are to be avoided in children with atopic dermatitis because they may act as an irritant, possibly exacerbating the condition. Also, bubble baths deplete the skin of its natural moisturizers. The issue is not whether the child bathes every night. Rather, the goal is to decrease dryness and itching.

 CN: Physiological adaptation; CL: Evaluate

5. 3. Impetigo involving several superficial lesions is usually treated topically, including washing the affected areas, removing crusts, and applying antibiotic ointment several times a day. The child can return to day care or school after being treated for 24 hours. The lesions do not need to be covered, and they can remain open to the air. There is no need for follow-up unless the lesions have not resolved or have become more severe.

 CN: Physiological adaptation; CL: Create

6. 4. Scabies is caused by the scabies mite, *Sarcoptes scabiei*. The mite burrows into the stratum corneum of the epidermis, where the female deposits eggs and fecal material. These burrows are linear. Scabies is highly contagious. The length of time from infestation to physical symptoms is 30 to 60 days, so everyone in close contact with the child will need to be treated. The bed linens and the child's clothing should be washed in hot water and dried on the hot setting. It is not necessary to damp mop the floors to prevent the spread of scabies. The child should be held minimally until treatment is completed. Family members should wash their hands after contact with the child. Itching lasts for 2 to 3 weeks until the stratum corneum is replaced.

 CN: Safety and infection control; CL: Create

The Client with Burns

7. 3. To prevent further injury to the skin, the mother should apply cool water to the burn site. Doing so causes vasoconstriction, retards further damage to tissues, and decreases fluid loss. Keeping the child warm promotes vasodilation, increases fluid loss, and decreases blood pressure and, thus, circulation to the area. Applying ointment to the burn is contraindicated because it does not allow healing to occur and may need to be removed in the hospital. Only a clean cloth should be used to cover the wound to prevent contamination or decrease pain or chilling. If only the arm is burned, a call to 911 for emergency care is not necessary, but the mother should seek health care services immediately.

 CN: Health promotion and maintenance; CL: Synthesize

8. 250 mL/h

$$2,000 \text{ mL} \div 8\text{h} = 250 \text{ mL/h}$$

 CN: Pharmacological and parenteral therapies; CL: Apply

9. 2. Expressions of anger and combativeness are often the result of loss of control and a feeling of powerlessness. Some control over the situation is regained by allowing the child to participate in care. Although having parental support during the dressing changes may be helpful, this action does nothing to allow the child control. Giving the child permission to cry may help with verbalizing feelings, but doing so does nothing to provide the child with control over the situation. Although allowing the child to determine the time for dressing changes may provide a sense of control over the situation, doing so is inappropriate because the dressing changes need to be performed as prescribed to ensure effectiveness and healing.

 CN: Physiological adaptation; CL: Synthesize

10. 2. Withholding certain foods until the child complies is punitive and rarely successful. Allowing the mother to feed the child, serving smaller and more frequent meals, and offering finger foods are all acceptable interventions for a 5-year-old child. This is true whether the child is well or ill.

 CN: Basic care and comfort; CL: Evaluate

11. 1. Hypoproteinemia is common after severe burns. The child's diet should be high in protein to compensate for protein loss and to promote tissue healing. The child will also require a diet that is high in calories and rich in iron. The menu of bacon, lettuce, and tomato sandwich; milk; and celery sticks is lacking in sufficient protein and calories.

 CN: Physiological adaptation; CL: Evaluate

12. 3. A child with moderate burns is at high risk for contractures. A position of comfort would encourage contracture formation. Therefore, splints need to be applied to maintain proper positioning and joint function, thereby preventing contractures and loss of function. Allowing the child to lie on the abdomen or with the hips and knees flexed often encourages contracture formation.

CN: Reduction of risk potential; CL: Synthesize

The Client with a Thyroid Problem

13. 3. Most clients will need lifelong thyroid replacement after treatments with radioactive iodine. Most clients are treated as outpatients. To reduce the risk of exposure to radioactivity to others, clients are advised to avoid public places for at least 1 day and maintain a prudent distance from others for 2 to 3 days. Additionally, clients are advised to avoid close contact with pregnant women and children for 5 to 11 days. The use of radioiodine to treat Graves' disease has not been found to affect long-term fertility. Clients are taught not to share food, utensils, and towels. Use of a private bathroom is desirable. Clients are also instructed to flush the toilet more than one time after each use.

CN: Safety and infection control; CL: Evaluate

14. 1,2,4,5. Hypothyroidism is a disorder in which the levels of active thyroid hormone are decreased. Clinical manifestations include cool extremities, mottling, umbilical hernia, lethargy, constipation, muscle weakness, and a hoarse cry. Hyperthyroidism occurs when thyroid hormone levels are increased. Clinical manifestations include increased appetite, goiter, irritability, prominent eyes, and tachycardia.

CN: Physiological adaptation; CL: Analysis

15. 3. Children with hyperthyroidism experience emotional lability that may strain interpersonal relationships. Focusing on one friend is easier than adapting to group dynamics until the child's condition improves. Because of their high metabolic rate, children with hyperthyroidism feel too warm. Bright sunshine may be irritating because of disease-related ophthalmopathy. Sweating is common, and bathing should be encouraged.

CN: Physiological adaptation; CL: Synthesize

16. 4. Because it takes approximately 2 weeks before the response to drug treatment occurs, much of the child's care focuses on managing the child's physical symptoms. Signs and symptoms of the disorder include inability to sit still or concentrate, increased appetite with weight loss, emotional lability,

and fatigue. Nursing care is directed toward ensuring that the mother and teacher know how to handle the child, suggesting a shortened school day, a nonstimulating environment, and decreased stress and workload. The child should be encouraged to eat a well-balanced diet.

CN: Physiological adaptation; CL: Create

The Client with Insulin-Dependent Diabetes Mellitus

17. 2. The 15-15 rule is a general guideline for treating hypoglycemia where the client consumes 15 g of carbohydrate and repeats testing the blood sugar in 15 minutes. Fifteen grams of carbohydrate equals 60 calories and is roughly equal to $\frac{1}{2}$ cup (120 mL) of juice or soda, six to eight Life Savers, or a tablespoon of honey or sugar. The general recommendation is if the blood sugar is still low, the client may repeat the sequence. Fifteen milliliters of juice would only provide 8 calories. This would not be sufficient carbohydrates to treat the hypoglycemia. Protein does not treat insulin-related hypoglycemia; however, a protein-starch snack may be offered after the blood glucose improves. Fifteen ounces of juice would be approximately 440 mL—almost four times the recommended 4 oz (120 mL) of juice.

CN: Physiological adaptation; CL: Synthesize

18. 4. Self-efficacy, or the belief that one can act in a way to produce a desired outcome, can be promoted through the observation of role models. Peers are particularly effective role models because clients can more readily identify with them and believe they are capable of similar behaviors. Providing a written plan alone does not promote self-efficacy. Having parents eliminate junk food and having the school nurse weigh the adolescent can be part of the plan, but these actions do not empower the client.

CN: Management of care; CL: Synthesize

19. 3. Metformin is currently approved by the FDA and Health Canada to treat type 2 diabetes in children. The medication decreases glucogenesis in the liver and increases insulin sensitivity in the peripheral tissues. Only insulin can actually replace insulin. This treatment is reserved for clients with type 1 diabetes or those with type 2 who do not respond to diet, exercise, and an oral diabetic agent. Other oral medications used to treat diabetes augments

insulin production or decreases carbohydrate absorption, but those medications are primarily used in adults.

CN: Pharmacological and parenteral therapies; CL: Apply

20. 4. The child is using the correct injection technique, and the nurse can remind the child to rotate sites. The nurse should also reinforce that the child has used the correct technique and praise the child for doing so. If the child can manipulate the plunger of the syringe with one hand, this is appropriate. Insulin is administered at a 90-degree angle as shown. The child should identify appropriate sites on the thighs as one handbreadth below the hip and above the knee; the child is using appropriate sites.

CN: Health promotion and maintenance; CL: Apply

21. Four units. Each carbohydrate food exchange has 15 g of carbohydrate. Two units are needed to cover the current blood glucose, and 2 units are needed to cover the anticipated carbohydrate intake.

CN: Pharmacological and parenteral therapies; CL: Apply

22. 3. Intermediate-acting insulin peaks in 6 to 8 hours, which would occur during sleep. A bedtime snack is needed to prevent late night hypoglycemia. The snack is not given to help regain weight. Milk contains fat and protein, which cause delayed absorption into the bloodstream, and maintains the blood glucose level at night when the intermediate-acting insulin will peak. The snack is not used to provide carbohydrates for immediate use because an intermediate-acting insulin, unlike regular insulin, does not peak immediately. The snack has nothing to do with a diet.

CN: Psychosocial integrity; CL: Apply

23. 2. The child needs more insulin during an illness, because the cells become more insulin resistant during illness and need more insulin to achieve a normal blood glucose level. Glucose levels rise with illness; therefore, more food calories are not needed. During an acute illness, simple carbohydrates and fluids are usually tolerated best.

CN: Physiological adaptation; CL: Evaluate

24. 1,2,6. Weakness, thirst, and dizziness are symptoms related to

dehydration caused by excretion of large amounts of glucose and water in the urine. The nurse should notify the **healthcare provider (HCP)** . Shakiness, hunger, headache, and irritability are related to hypoglycemia and result from the brain and other cells being starved for nutrients.

 CN: Physiological adaptation; CL: Analyze

25. 2. The ability to talk about her diabetes indicates that the adolescent feels good enough about herself to share her problem with her peers. Asking for reference material does not specifically indicate that the client's self-esteem has improved or that she has accepted her diagnosis. Saying that her friends will probably desert her if she tells them about the illness indicates that the adolescent still needs to work on her self-esteem and her feelings about the disease. Asking her friends what they think of someone with a lifelong illness would not indicate that the nurse's interventions targeted toward improving self-esteem have been successful. Rather, this statement demonstrates the adolescent's uncertainty about herself.

 CN: Psychosocial integrity; CL: Evaluate

26. 1. Repeated use of the same injection site can result in atrophy of the fat in the subcutaneous tissue and lead to poor insulin absorption. The neuritis that develops from diabetes is related to microvascular changes that occur. Subcutaneous tissue is not destroyed, and insulin is not rapidly absorbed. Resistance to insulin is caused by an immune response to the insulin protein.

 CN: Pharmacological and parenteral therapies; CL: Evaluate

The Client with Polycystic Ovarian Syndrome

27. 4. While pregnancy may be difficult for some clients, the nurse must work to prevent the false conception that a sexually active teen with PCOS does not need to use a reliable form of birth control. PCOS is associated with high levels of androgens and excessive insulin. It is the excess insulin that is thought to increase androgen production. Clients with PCOS are at risk for type 2 diabetes. Initial treatment focuses on weight management and exercise. These measures often reduce insulin production and restore normal menstrual cycles.

 CN: Physiologic adaptation; CL: Evaluate

28. 2,3,4,5. PCOS is associated with obesity, increased body or facial hair (hirsutism), acne, and darkening of the skin usually in body folds (acanthosis nigricans). When a female has never had a menstrual cycle, it is referred to as primary amenorrhea. PCOS is associated with irregular menstrual cycles and/or secondary amenorrhea, not primary amenorrhea. High androgen levels frequently lead to decreased versus enlarged breast size.

 CN: Physiologic adaptation; CL: Analyze

29. 3. Metformin works by decreasing the production of glucose in the liver and improving insulin sensitivity. These two mechanisms reduce insulin and blood glucose level. Reducing insulin levels reduces androgens and helps to restore menstruation.

 CN: Pharmacology and parental therapies; CL: Evaluate

30. 2. Many clients with PCOS suffer from depression. As depression is associated with a significant risk of suicide, the priority would be to determine if the client has symptoms of depression requiring further evaluation and treatment. Referrals to a hair removal specialist and possibly a support group would be appropriate, but only after determining if the client needs a referral for a major mood disorder. Providing more information on causes and treatment options is better saved for when the client is less distraught.

 CN: Psychosocial integrity; CL: Analyze

Managing Care, Quality, and Safety of Children with Dermatologic and Endocrine Health Problems

31. 3. Confidentiality legislation specifies that institutions designate a “privacy officer” who is responsible for developing and implementing privacy policies. This would be the very best resource for the nurse to contact. Depending on the nurse manager’s experience, he or she may or may not know the answer and may have to consult the privacy officer. While **HCPs**  would have an understanding of confidentiality laws, it is unlikely they understand the specifics of nursing policies. The customer service

representatives typically address client concerns or complaints. At this time, the family has not voiced a complaint.

 CN: Management of care; CL: Apply

32. 2. Sleeping in the same room with a person of the opposite sex may be viewed as a violation of norms by persons of conservative faiths. If at all possible, the charge nurse should reassign the family to a different room. While it makes sense to have two clients with similar educational needs in the same room, it is likely that the arrangement would be distressing enough to create a learning barrier. Offering the mother another place to sleep deprives the child of her parent at night. The customer service representative would only need to be involved if it became impossible to accommodate the mother's needs.

 CN: Management of care; CL: Synthesize

33. 1. Blood sugar levels can go up during the flu; therefore, blood glucose levels should be monitored every 3 to 4 hours during flu. Because glucose levels are higher when a client has the flu, clients should continue to take diabetes medications as ordered. If blood sugar level is over 240 mg/dL, ketones should be checked. If ketones are present, the client should be encouraged to drink calorie-free fluids and eat small meals.

 CN: Management of care; CL: Synthesize

34. 4. Treating pediatric clients with severe DKA is a medical emergency; therefore, attending to the airway, breathing, and circulation is the first priority. Once the airway is secured, the healthcare team should estimate the level of dehydration and begin replacement fluids of normal saline. An insulin drip should be started after the initial 1 to 2 hours of treatment at a rate of 0.1 units/kg/h. Blood glucose should be tested every 1 to 2 hours until the client is stable, then it should be every 6 hours. Additionally, serum electrolytes should be drawn every 1 to 2 hours until the client is stable, then every 4 to 6 hours.

 CN: Management of care; CL: Synthesis

35. 2. The nurse's first response should be to obtain more information about the mother's concerns. It is true that the child may have a diabetic

reaction anywhere at school, and it is advisable that her teacher, classmates, and other adults know about her diabetes in order to help her; however, it is ultimately the client and her parents who will make the decision about informing the school. The nurse can facilitate a dialogue that will help the mother reach this decision. Dictating to the mother does not explain any rationale for the necessity of the information. Telling the mother that her daughter will tell the school does not address the mother's concerns.

CN: Safety and infection control; CL: Synthesize

The Nursing Care of Adults with Medical and Surgical Health Problems

TEST

1

The Client with Cardiac Health Problems

- The Client with Acute Coronary Syndromes
- The Client with Heart Failure
- The Client with Valvular Heart Disease
- The Client with Hypertension
- The Client with Atrial Fibrillation and Other Dysrhythmias
- The Client Requiring Rapid Response or Cardiopulmonary Resuscitation
- Managing Care, Quality, and Safety for Clients with Cardiac Health Problems
- Answers, Rationales, and Test-Taking Strategies

The Client with Acute Coronary Syndromes

1. A client returns from a left heart catheterization. The right groin was used for catheter access. In which location should the nurse palpate the distal pulse on this client?

- ☐ 1. anterior to the right tibia
- ☐ 2. dorsal surface of the right foot
- ☐ 3. posterior to the right knee
- ☐ 4. right midinguinal area

2. A client is admitted with chest pain and kept overnight for stress testing the next morning. Prior to sending the client to the stress test, the nurse reviews the results of the laboratory reports (see lab report). The nurse should report which elevated laboratory value to the healthcare provider (HCP) prior to the stress test?

- ☐ 1. cholesterol level
- ☐ 2. erythrocyte sedimentation rate
- ☐ 3. prothrombin time
- ☐ 4. troponin

3. A client has chest pain rated at 8 on a 10-point visual analog scale. The 12-lead electrocardiogram reveals ST elevation in the inferior leads, and troponin levels are elevated. What should the nurse do **first**?

- ☐ 1. Monitor daily weights and urine output.
- ☐ 2. Limit visitation by family and friends.
- ☐ 3. Provide client education on medications and diet.
- ☐ 4. Reduce pain and myocardial oxygen demand.

4. A client with chest pain is prescribed intravenous nitroglycerin. Which assessment is of **greatest** concern for the nurse initiating the nitroglycerin drip?

- ☐ 1. Serum potassium is 3.5 mEq/L (3.5 mmol/L).
- ☐ 2. Blood pressure is 88/46 mm Hg.
- ☐ 3. ST elevation is present on the electrocardiogram.
- ☐ 4. Heart rate is 61 bpm.

5. The nurse is caring for a client diagnosed with an anterior myocardial infarction 2 days ago. Upon assessment, the nurse identifies a systolic murmur at the apex. The nurse should **first**:

- ☐ 1. assess for changes in vital signs.
- ☐ 2. draw an arterial blood gas.
- ☐ 3. evaluate heart sounds with the client leaning forward.
- ☐ 4. obtain a 12-lead electrocardiogram.

6. A client with acute chest pain is receiving IV morphine sulfate. Which is an expected effect of morphine? Select all that apply.

- ☐ 1. reduces myocardial oxygen consumption
- ☐ 2. promotes reduction in respiratory rate
- ☐ 3. prevents ventricular remodeling
- ☐ 4. reduces blood pressure and heart rate
- ☐ 5. reduces anxiety and fear

7. A client is receiving an IV infusion of heparin sodium at 1,200 units/h. The dilution is 25,000 units/500 mL. How many milliliters per hour will this client receive? Round your answer to a whole number.

_____ mL/h.

8. An older adult has chest pain and shortness of breath. The healthcare provider (HCP) prescribes nitroglycerin tablets. What should the nurse instruct the client to do?

- ☐ 1. Put the tablet under the tongue until it is absorbed.
- ☐ 2. Swallow the tablet with 120 mL of water.
- ☐ 3. Chew the tablet until it is dissolved.
- ☐ 4. Place the tablet between the cheek and gums until it disappears.

9. The nurse has completed an assessment on a client with a decreased cardiac output. Which findings should receive the **highest priority**?

- ☐ 1. BP 110/62 mm Hg, atrial fibrillation with HR 82, bilateral basilar crackles
- ☐ 2. confusion, urine output 15 mL over the last 2 hours, orthopnea
- ☐ 3. SpO₂ 92 on 2 L nasal cannula, respirations 20, 1+ edema of lower extremities
- ☐ 4. weight gain of 1 kg in 3 days, BP 130/80, mild dyspnea with exercise

10. The nurse notices that a client's heart rate decreases from 63 to 50 bpm on the monitor. The nurse should **first**:

- ☐ 1. administer atropine 0.5 mg IV push.
- ☐ 2. auscultate for abnormal heart sounds.
- ☐ 3. prepare for transcutaneous pacing.
- ☐ 4. take the client's blood pressure.

11. When preparing a client for a cardiac angiogram, what actions should

the nurse take? Select all that apply.

- ☐ 1. Determine if the client has an allergy to liquid contrast material.
- ☐ 2. Inform the client that an intravenous infusion will be started before the procedure.
- ☐ 3. Remind the client to have nothing to eat or drink 8 hours before the procedure.
- ☐ 4. Instruct the client to remain still during the procedure.
- ☐ 5. Explain that the client will receive a fast-acting acting anesthetic.

12. A client is admitted with a myocardial infarction and atrial fibrillation. While auscultating the heart, the nurse notes an irregular heart rate and hears an extra heart sound at the apex after the S₂ that remains constant throughout the respiratory cycle. The nurse should document these findings as:

- ☐ 1. heart rate irregular with S₃.
- ☐ 2. heart rate irregular with S₄.
- ☐ 3. heart rate irregular with aortic regurgitation.
- ☐ 4. heart rate irregular with mitral stenosis.

13. A 60-year-old comes into the emergency department with crushing substernal chest pain that radiates to the shoulder and left arm. The admitting diagnosis is acute myocardial infarction (MI). Admission prescriptions include oxygen by nasal cannula at 4 L/min, complete blood count (CBC), a chest radiograph, a 12-lead electrocardiogram (ECG), and 2 mg of morphine sulfate given IV. The nurse should **first**:

- ☐ 1. administer the morphine.
- ☐ 2. obtain a 12-lead ECG.
- ☐ 3. obtain the blood work.
- ☐ 4. prescribe the chest radiograph.

14. An older adult had a myocardial infarction (MI) 4 days ago. At 0930, the client's blood pressure is 102/64 mm Hg. After reviewing the client's progress notes (see chart), the nurse should **first**:

Nurses Progress Notes

Date	1/10
Time	0030
Urinary output for the last 4 hours	90 mL
Capillary refill	>3 seconds
Blood pressure	128/82
Extremities	Cool
	D. Smith, RN

- ☐ 1. give a fluid challenge/bolus.
- ☐ 2. notify the healthcare provider (HCP).
- ☐ 3. assist the client to walk.
- ☐ 4. administer furosemide as prescribed.

15. When administering a thrombolytic drug to the client who is experiencing a myocardial infarction (MI) and who has premature ventricular contractions, the expected outcome of the drug is to:

- ☐ 1. promote hydration.
- ☐ 2. dissolve clots.
- ☐ 3. prevent kidney failure.
- ☐ 4. treat dysrhythmias.

16. The nurse is assessing a client who has had a myocardial infarction (MI). The nurse notes the cardiac rhythm on the monitor (see the electrocardiogram strip). The nurse should:

- ☐ 1. notify the healthcare provider (HCP).
- ☐ 2. call the rapid response team.

- ☐ 3. assess the client for changes in the rhythm.
- ☐ 4. administer lidocaine as prescribed.

17. The nurse is assessing a client who has had a stent inserted in a coronary artery via the right femoral artery. The client is receiving intravenous heparin sodium at 1,000 units per hour. During the second postprocedure check, the nurse notes that the puncture site at the groin has begun to steadily ooze blood. The nurse should **first**:

- ☐ 1. don gloves and apply direct pressure over the site.
- ☐ 2. observe and document the bleeding.
- ☐ 3. notify the healthcare provider (HCP).
- ☐ 4. prepare protamine sulfate for intravenous administration.

18. A client admitted for a myocardial infarction (MI) develops cardiogenic shock. An arterial line is inserted. Which prescription from the healthcare provider should the nurse verify before implementing?

- ☐ 1. Call for urine output < 30 mL/h for 2 consecutive hours.
- ☐ 2. Administer metoprolol 5 mg IV push.
- ☐ 3. Prepare for a pulmonary artery catheter insertion.
- ☐ 4. Titrate dobutamine to keep systolic BP > 100 mm Hg.

19. The nurse is monitoring a client admitted with a myocardial infarction (MI) who is at risk for cardiogenic shock. The nurse should report which changes noted from the client's chart to the healthcare provider (HCP)?

Nurses Progress Notes

	1300	1500	
BP	110/70	100/65	
T	98.7 (37.1)	99 (37.2)	
HR	70	75	
R	20	26	
Urine output	90 mL/h	20 mL/h	

- ☐ 1. urine output
- ☐ 2. heart rate
- ☐ 3. blood pressure
- ☐ 4. respiratory rate

20. The healthcare provider (HCP) prescribes continuous IV nitroglycerin infusion for the client with myocardial infarction. The nurse should:

- ☐ 1. obtain an infusion pump for the medication.
- ☐ 2. take the blood pressure every 4 hours.
- ☐ 3. monitor urine output hourly.
- ☐ 4. obtain serum potassium levels daily.

21. The client is admitted to the telemetry unit due to chest pain. The client has polysubstance abuse, and the nurse assesses that the client is anxious and irritable and has moist skin. What should the nurse do in order of priority from first to last? All options must be used.

1. Obtain a history of which drugs the client has used recently.

2. Administer the prescribed dose of morphine.

3. Position electrodes on the chest.

4. Take vital signs.

22. A client is scheduled for insertion of a coronary stent with right groin access. Which teaching points should the nurse include in this client's preoperative teaching plan? Select all that apply.

- ☐ 1. "If you have a hearing aid, you will need to remove it prior to leaving for the procedure."
- ☐ 2. "If you have chest pain during this procedure, please tell the staff when or if this should occur."
- ☐ 3. "The stitches at your right groin will be able to be removed in 7 to 10 days following the procedure."
- ☐ 4. "You will be given general anesthesia and will be asleep for throughout this procedure."
- ☐ 5. "You will need to remain flat during the procedure and for 3 to 6 hours after the procedure."
- ☐ 6. "You will need to keep your right leg in a flexed position for 1 to 2 hours following the procedure."

23. The nurse is assessing a client who has had a myocardial infarction. The nurse notes the cardiac rhythm shown on the electrocardiogram strip. The nurse interprets this rhythm as:

- ☐ 1. atrial fibrillation.
- ☐ 2. ventricular tachycardia.
- ☐ 3. premature ventricular contractions.
- ☐ 4. sinus tachycardia.

24. While caring for a client who has sustained a myocardial infarction (MI), the nurse notes eight premature ventricular contractions (PVCs) in 1 minute on the cardiac monitor. The client is receiving an IV infusion of 5% dextrose in water (D₅W) at 125 mL/h and oxygen at 2 L/min. The nurse should **first**:

- ☐ 1. increase the IV infusion rate to 150 mL/h.
- ☐ 2. notify the healthcare provider (HCP).
- ☐ 3. increase the oxygen concentration to 4 L/min.
- ☐ 4. administer a prescribed analgesic.

25. Which is an expected outcome for a client on the 2nd day of hospitalization after a myocardial infarction (MI)? The client:

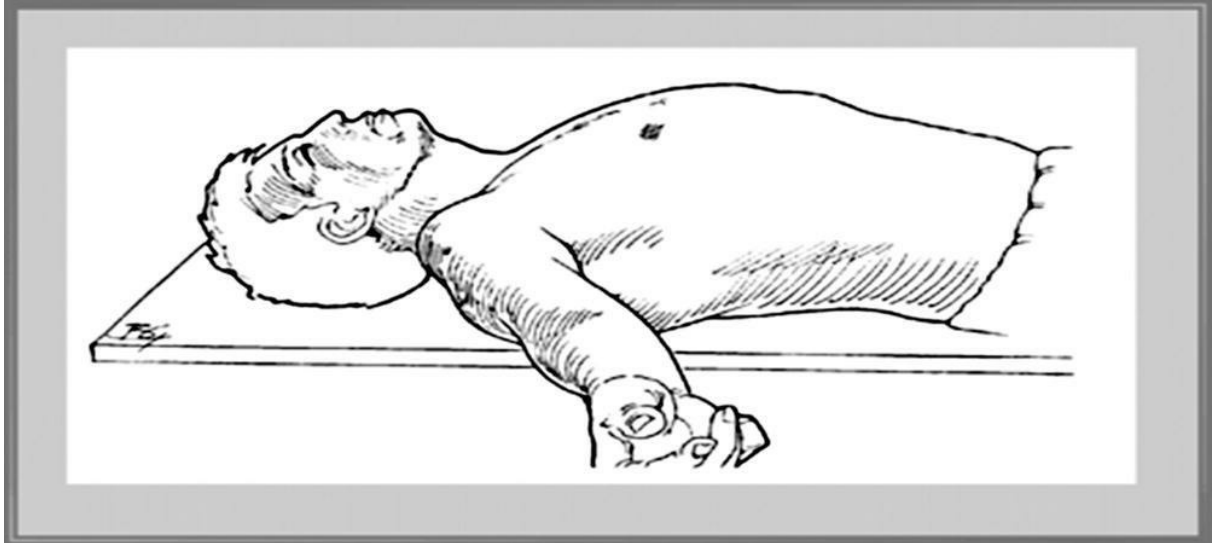

- ☐ 1. continues to have severe chest pain.
- ☐ 2. can identify risk factors for MI.
- ☐ 3. participates in a cardiac rehabilitation walking program.
- ☐ 4. can perform personal self-care activities without pain.

26. Which is an expected outcome when a client is receiving an IV administration of furosemide?

- ☐ 1. increased blood pressure
- ☐ 2. increased urine output
- ☐ 3. decreased pain

- ☐ 4. decreased premature ventricular contractions

27. The nurse is preparing to measure central venous pressure (CVP). Mark the spot on the torso indicating the location for leveling the transducer.

28. A client has had a pulmonary artery catheter inserted. In performing hemodynamic monitoring with the catheter, the nurse should wedge the catheter to gain information about:

- ☐ 1. cardiac output.
- ☐ 2. right atrial blood flow.
- ☐ 3. left end-diastolic pressure.
- ☐ 4. cardiac index.

29. After a myocardial infarction, the hospitalized client is taught to move the legs while resting in bed. What is the expected outcome of this exercise?

- ☐ 1. Prepare the client for ambulation.
- ☐ 2. Promote urinary and intestinal elimination.
- ☐ 3. Prevent thrombophlebitis and blood clot formation.
- ☐ 4. Decrease the likelihood of pressure ulcer formation.

30. Which is the **most** appropriate diet for a client during the acute phase of myocardial infarction?

- ☐ 1. liquids as desired
- ☐ 2. small, easily digested meals

- ☐ 3. three regular meals per day
- ☐ 4. nothing by mouth

31. The nurse is caring for a client who recently experienced a myocardial infarction and has been started on clopidogrel. The nurse should develop a teaching plan that includes which points? Select all that apply.

- ☐ 1. The client should report unexpected bleeding or bleeding that lasts a long time.
- ☐ 2. The client should take clopidogrel with food.
- ☐ 3. The client may bruise more easily and may experience bleeding gums.
- ☐ 4. Clopidogrel works by preventing platelets from sticking together and forming a clot.
- ☐ 5. The client should drink a glass of water after taking clopidogrel.

32. Which client is at **greatest** risk for coronary artery disease?

- ☐ 1. a 32-year-old female with mitral valve prolapse who quit smoking 10 years ago
- ☐ 2. a 43-year-old male with a family history of CAD and cholesterol level of 158 (8.8 mmol/L)
- ☐ 3. a 56-year-old male with an HDL of 60 (3.3 mmol/L) who takes atorvastatin
- ☐ 4. a 65-year-old female who is obese with an LDL of 188 (10.4 mmol/L)

33. The client has been managing angina episodes with nitroglycerin. Which finding indicates that the therapeutic effect of the drug has been achieved?

- ☐ 1. decreased chest pain
- ☐ 2. increased blood pressure
- ☐ 3. decreased blood pressure
- ☐ 4. decreased heart rate

34. A client has risk factors for coronary artery disease, including smoking cigarettes, eating a diet high in saturated fat, and leading a sedentary lifestyle. The nurse can coach this client to improve health by:

- ☐ 1. explaining how the risk factors lead to poor health.
- ☐ 2. withholding praise until the client changes the risky behavior.

- ☐ 3. helping the client establish a wellness vision to reduce the health risks.
- ☐ 4. instilling mild fear into the client about the potential outcomes of the risky health behaviors.

35. Alteplase recombinant, or tissue plasminogen activator (t-PA), a thrombolytic enzyme, is administered during the first 6 hours after onset of myocardial infarction (MI) to:

- ☐ 1. control chest pain.
- ☐ 2. reduce coronary artery vasospasm.
- ☐ 3. control the arrhythmias associated with MI.
- ☐ 4. revascularize the blocked coronary artery.

36. When monitoring a client who is receiving tissue plasminogen activator (t-PA), the nurse should have resuscitation equipment available because reperfusion of the cardiac tissue can result in:

- ☐ 1. cardiac arrhythmias.
- ☐ 2. hypertension.
- ☐ 3. seizure.
- ☐ 4. hypothermia.

37. Prior to administering tissue plasminogen activator (t-PA), the nurse should assess the client for which contradiction to administering the drug?

- ☐ 1. age > 60 years
- ☐ 2. history of cerebral hemorrhage
- ☐ 3. history of heart failure
- ☐ 4. cigarette smoking

38. A middle-aged client being admitted to the hospital has a history of hypertension and informs the nurse that his father died from a heart attack at age 60. The client reports having “indigestion.” The nurse connects the client to a cardiac monitor, which reveals eight premature ventricular contractions (PVCs) per minute. The nurse should **next**:

- ☐ 1. call the healthcare provider (HCP).
- ☐ 2. start an IV line.
- ☐ 3. obtain a portable chest radiograph.
- ☐ 4. draw blood for laboratory studies.

39. A 68-year-old client on day 2 after hip surgery has no cardiac history but reports having chest heaviness. The nurse should **first**:

- ☐ 1. inquire about the onset, duration, severity, and precipitating factors of the heaviness.
- ☐ 2. administer oxygen via nasal cannula.
- ☐ 3. offer pain medication for the chest heaviness.
- ☐ 4. inform the healthcare provider (HCP) of the chest heaviness.

40. Following diagnosis of angina pectoris, a client reports being unable to walk up two flights of stairs without pain. Which instruction would **most** likely help the client prevent this problem?

- ☐ 1. Climb the steps early in the day.
- ☐ 2. Rest for at least an hour before climbing the stairs.
- ☐ 3. Take a nitroglycerin tablet before climbing the stairs.
- ☐ 4. Lie down after climbing the stairs.

41. The client who experiences angina has been told to follow a low-cholesterol diet. Which meal would be **best**?

- ☐ 1. hamburger, salad, and milk shake
- ☐ 2. baked liver, green beans, and coffee
- ☐ 3. spaghetti with tomato sauce, salad, and coffee
- ☐ 4. fried chicken, green beans, and skim milk

42. Which symptom should the nurse teach the client with unstable angina to report **immediately** to the healthcare provider (HCP)?

- ☐ 1. a change in the pattern of the chest pain
- ☐ 2. pain during sexual activity
- ☐ 3. pain during an argument
- ☐ 4. pain during or after a physical activity

43. A client with unstable angina is scheduled to have a cardiac catheterization. The nurse explains to the client that this procedure is being used to:

- ☐ 1. open and dilate blocked coronary arteries.
- ☐ 2. assess the extent of arterial blockage.

- ☐ 3. bypass obstructed vessels.
- ☐ 4. assess the functional adequacy of the valves and heart muscle.

44. The nurse is caring for a client who has just returned from having a percutaneous transluminal balloon angioplasty with femoral artery access. In which order, from first to last, should the nurse obtain information about the client? All options must be used.

1. vital signs and oxygen saturation

2. pedal pulses

3. color and sensation of extremity

4. catheterization site

45. Which is **not** a risk factor for the development of atherosclerosis?

- ☐ 1. family history of early heart attack
- ☐ 2. late onset of puberty
- ☐ 3. total blood cholesterol level > 220 mg/dL (12.2 mmol/L)
- ☐ 4. elevated fasting blood glucose concentration

46. As an initial step in treating a client with angina, the healthcare provider (HCP) prescribes nitroglycerin tablets, 0.3 mg, given sublingually. This drug's principal effects are produced by:

- ☐ 1. antispasmodic effects on the pericardium.

- ☐ 2. causing an increased myocardial oxygen demand.
- ☐ 3. vasodilation of peripheral vasculature.
- ☐ 4. improved conductivity in the myocardium.

47. A client has a throbbing headache when nitroglycerin is taken for angina. The nurse should instruct the client that:

- ☐ 1. acetaminophen or ibuprofen can be taken for this common side effect.
- ☐ 2. nitroglycerin should be avoided if the client is experiencing this serious side effect.
- ☐ 3. taking the nitroglycerin with a few glasses of water will reduce the problem.
- ☐ 4. the client should lie in a supine position to alleviate the headache.

48. How should the nurse instruct the client with unstable angina to use sublingual nitroglycerin tablets when chest pain occurs? “Sit down and then:

- ☐ 1. take one tablet every 2 to 5 minutes until the pain stops.”
- ☐ 2. take one tablet and rest for 15 minutes. Call the healthcare provider if pain persists after 15 minutes.”
- ☐ 3. take one tablet; then if the pain persists, take additional two tablets in 5 minutes. Call the healthcare provider if pain persists after 15 minutes.”
- ☐ 4. take one tablet. If pain persists after 5 minutes, call 911.”

49. A client with angina is taking nifedipine. What instruction should the nurse give the client?

- ☐ 1. Monitor blood pressure monthly.
- ☐ 2. Perform daily weights.
- ☐ 3. Inspect gums daily.
- ☐ 4. Limit intake of green leafy vegetables.

50. The nurse is developing a teaching plan for a client who will be starting a prescription for simvastatin 40 mg/day. What instructions should the nurse give the client? Select all that apply.

- ☐ 1. “Take once a day in the morning.”
- ☐ 2. “If you miss a dose, take it when you remember it.”
- ☐ 3. “Limit greens such as lettuce in the diet to prevent bleeding.”
- ☐ 4. “Be sure to take the pill with food.”

- ☐ 5. “Report muscle pain or tenderness to your healthcare provider.”
- ☐ 6. “Continue to follow a diet that is low in saturated fats.”

The Client with Heart Failure

51. Captopril, furosemide, and metoprolol are prescribed for a client with systolic heart failure. The client’s blood pressure is 136/82 mm Hg, and the heart rate is 65 bpm. Prior to medication administration at 0900, the nurse reviews the following lab tests (see chart). What should the nurse do **first**?

Laboratory Results

Sodium	140 mEq/L (140 mmol/L)
Potassium	6.8 mEq/L (6.8 mmol/L)
BUN	18 mg/dL (6.4 mmol/L)
Creatinine	1.0 mg/dL (76.3 μ mol/L)
Hemoglobin	12 g/dL (120 g/L)
Hematocrit	37% (0.37)

- ☐ 1. Administer the medications.
- ☐ 2. Call the healthcare provider (HCP).
- ☐ 3. Withhold the captopril.
- ☐ 4. Question the metoprolol dose.

52. A client with chronic heart failure has atrial fibrillation and a left ventricular ejection fraction of 15%. The client is taking warfarin. The expected outcome of this drug is to:

- ☐ 1. decrease circulatory overload.
- ☐ 2. improve the myocardial workload.
- ☐ 3. prevent thrombus formation.
- ☐ 4. regulate cardiac rhythm.

53. A client has a history of heart failure and has been prescribed furosemide, digoxin, and potassium chloride. The client has nausea, blurred vision, headache, and weakness. The nurse notes that the client is confused. The telemetry strip shows first-degree atrioventricular block. The nurse should assess the client for signs of:

- ☐ 1. hyperkalemia.
- ☐ 2. digoxin toxicity.
- ☐ 3. fluid deficit.
- ☐ 4. pulmonary edema.

54. The nurse should assess the client with left-sided heart failure for which findings? Select all that apply.

- ☐ 1. dyspnea
- ☐ 2. jugular vein distention (JVD)
- ☐ 3. crackles
- ☐ 4. right upper quadrant pain
- ☐ 5. oliguria
- ☐ 6. decreased oxygen saturation levels

55. Which are indications that a client with a history of left-sided heart failure is developing pulmonary edema? Select all that apply.

- ☐ 1. distended jugular veins
- ☐ 2. dependent edema
- ☐ 3. anorexia
- ☐ 4. coarse crackles
- ☐ 5. tachycardia

56. An older adult with a history of heart failure is admitted to the emergency department with pulmonary edema. On admission, what should the nurse assess **first**?

- ☐ 1. blood pressure
- ☐ 2. skin breakdown
- ☐ 3. serum potassium level
- ☐ 4. urine output

57. The nurse is caring for an older adult with mild dementia admitted with heart failure. What nursing care will be helpful for this client in reducing potential confusion related to hospitalization and change in routine? Select all that apply.

- ☐ 1. Reorient frequently to time, place, and situation.
- ☐ 2. Put the client in a quiet room furthest from the nursing station.
- ☐ 3. Perform necessary procedures quickly.
- ☐ 4. Arrange for familiar pictures or special items at bedside.
- ☐ 5. Limit the client's visitors.
- ☐ 6. Spend time with the client, establishing a trusting relationship.

58. The nurse is assessing a client with chronic heart failure who is demonstrating neurohormonal compensatory mechanisms. Which are expected findings on assessment? Select all that apply.

- ☐ 1. decreased cardiac output
- ☐ 2. increased heart rate
- ☐ 3. vasoconstriction in skin, GI tract, and kidneys
- ☐ 4. decreased pulmonary perfusion
- ☐ 5. fluid overload

59. Furosemide 40 mg intravenous push (IVP) is prescribed. Furosemide 10 mg/mL is available. How much should the nurse administer? Round your answer to a whole number.

_____ mL.

60. Which position is **best** for a client with heart failure who has orthopnea?

- ☐ 1. semisitting (low Fowler's position) with legs elevated on pillows
- ☐ 2. lying on the right side (Sims' position) with a pillow between the legs
- ☐ 3. sitting upright (high Fowler's position) with legs resting on the mattress
- ☐ 4. lying on the back with the head lowered (Trendelenburg's position) and legs elevated

61. What is the major goal of nursing care for a client with heart failure

and pulmonary edema?

- ☐ 1. Increase cardiac output.
- ☐ 2. Improve respiratory status.
- ☐ 3. Decrease peripheral edema.
- ☐ 4. Enhance comfort.

62. A client with heart failure is receiving digoxin intravenously. The nurse should determine the effectiveness of the drug by assessing:

- ☐ 1. dilated coronary arteries.
- ☐ 2. increased myocardial contractility.
- ☐ 3. decreased cardiac arrhythmias.
- ☐ 4. decreased electrical conductivity in the heart.

63. Furosemide is administered intravenously to a client with heart failure. How soon after administration should the nurse begin to see evidence of the drug's desired effect?

- ☐ 1. 5 to 10 minutes
- ☐ 2. 30 to 60 minutes
- ☐ 3. 2 to 4 hours
- ☐ 4. 6 to 8 hours

64. The nurse teaches a client with heart failure to take oral furosemide in the morning. The **primary** reason for this is to prevent:

- ☐ 1. electrolyte imbalances.
- ☐ 2. nausea or vomiting.
- ☐ 3. excretion of excessive fluids accumulated during the night.
- ☐ 4. sleep disturbances during the night.

65. The nurse should teach the client that signs of digoxin toxicity include:

- ☐ 1. rash over the chest and back.
- ☐ 2. increased appetite.
- ☐ 3. visual disturbances such as seeing yellow spots.
- ☐ 4. elevated blood pressure.

66. The nurse should assess the client for digoxin toxicity if serum levels indicate that the client has a:

- ☐ 1. low sodium level.
- ☐ 2. high glucose level.
- ☐ 3. high calcium level.
- ☐ 4. low potassium level.

67. Which food should the nurse teach a client with heart failure to limit when following a 2-g sodium diet?

- ☐ 1. apples
- ☐ 2. canned tomato juice
- ☐ 3. whole wheat bread
- ☐ 4. beef tenderloin

68. A client receiving a loop diuretic should be encouraged to eat which foods? Select all that apply.

- ☐ 1. angel food cake
- ☐ 2. banana
- ☐ 3. dried fruit
- ☐ 4. orange juice
- ☐ 5. peppers

69. When assessing an older adult, the nurse finds the apical impulse below the fifth intercostal space. The nurse should further assess the client for:

- ☐ 1. left atrial enlargement.
- ☐ 2. left ventricular enlargement.
- ☐ 3. right atrial enlargement.
- ☐ 4. right ventricular enlargement.

70. The nurse is admitting an older adult to the hospital. The echocardiogram report revealed left ventricular enlargement. The nurse notes 2+ pitting edema in the ankles when getting the client into bed. Based on this finding, what should the nurse do **first**?

- ☐ 1. Assess respiratory status.
- ☐ 2. Draw blood for laboratory studies.
- ☐ 3. Insert a Foley catheter.

- ☐ 4. Weigh the client.

71. The nurse's discharge teaching plan for the client with heart failure should emphasize the importance of:

- ☐ 1. maintaining a high-fiber diet.
- ☐ 2. walking 2 miles (3.2 km) every day.
- ☐ 3. obtaining daily weights at the same time each day.
- ☐ 4. remaining sedentary for most of the day.

72. The nurse is teaching a client with heart failure how to avoid complications and future hospitalizations. The nurse is confident that the client has understood the teaching when the client identifies which potential complications? Select all that apply.

- ☐ 1. becoming increasingly short of breath at rest
- ☐ 2. weight gain of 2 lb (0.9 kg) or more in 1 day
- ☐ 3. high intake of sodium for breakfast
- ☐ 4. having to sleep sitting up in a reclining chair
- ☐ 5. weight loss of 2 lb (0.9 kg) in 1 day

The Client with Valvular Heart Disease

73. A client has returned from the cardiac catheterization laboratory after a balloon valvuloplasty for mitral stenosis. Which finding requires **immediate** nursing action?

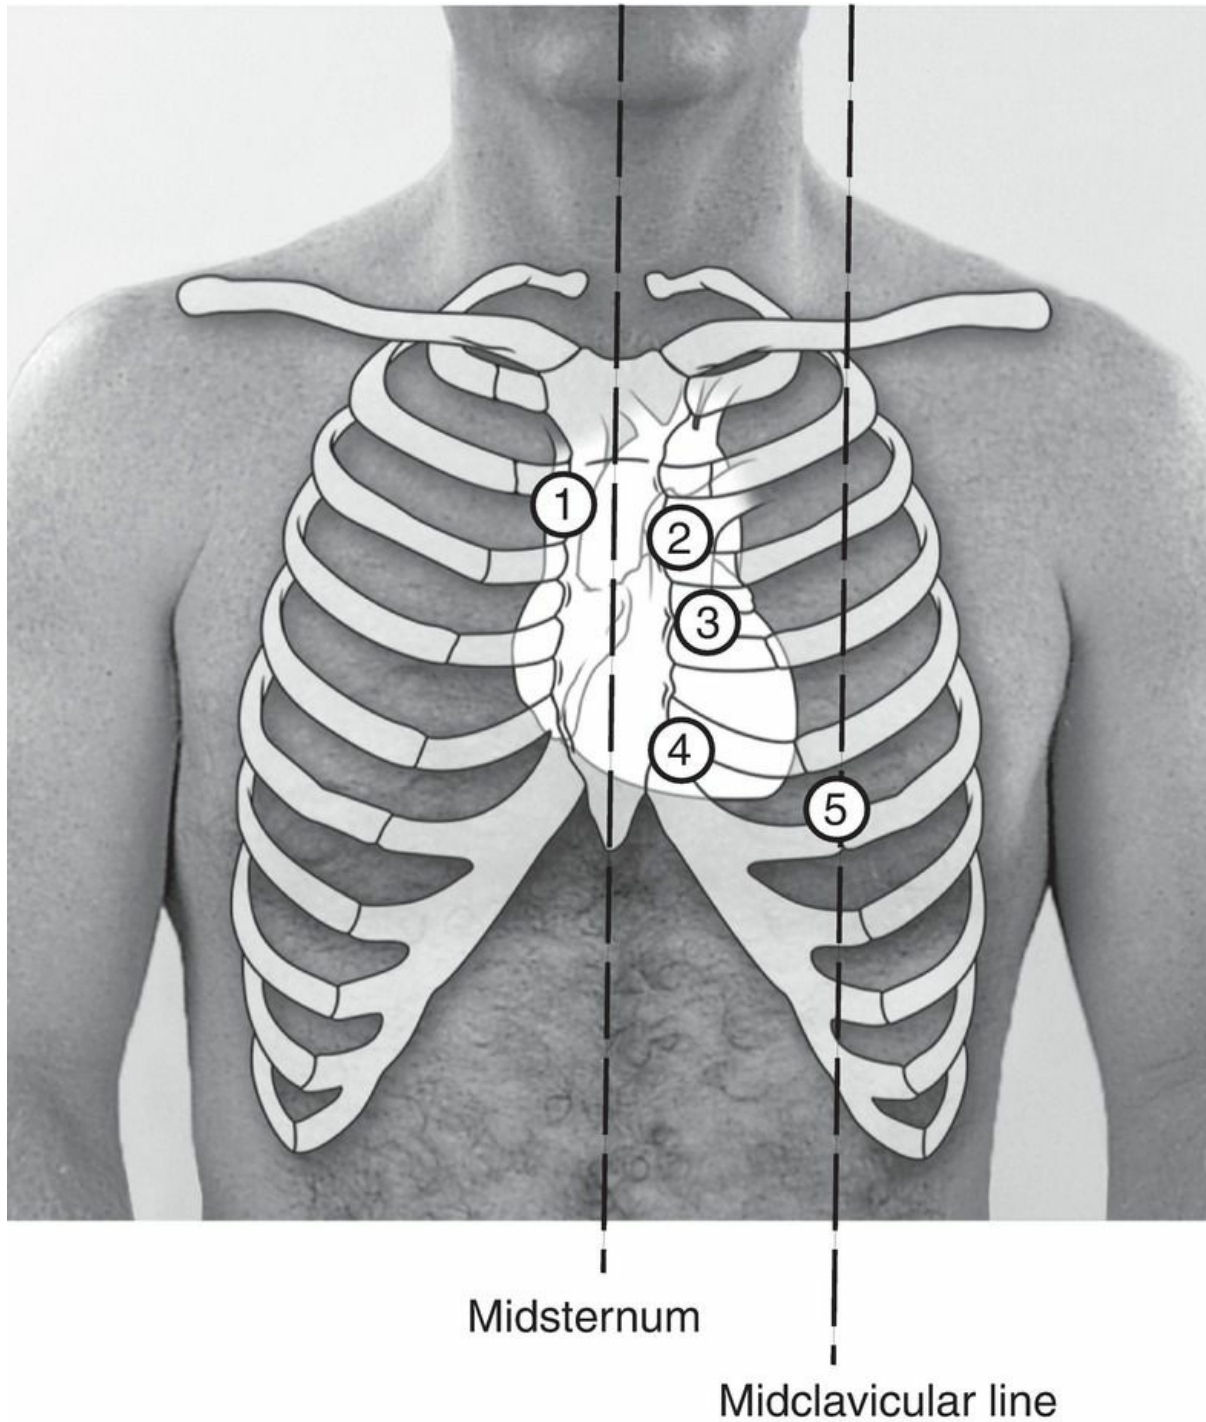

- ☐ 1. There is a low, grade 1 intensity mitral regurgitation murmur.
- ☐ 2. SpO₂ is 94% on 2 L of oxygen via nasal cannula.
- ☐ 3. Client has become more somnolent.
- ☐ 4. Urine output decreased from 60 mL/h to 40 mL over the last hour.

74. An older client with diabetes who has been maintained on metformin has been scheduled for a cardiac catheterization. The nurse should verify that the healthcare provider (HCP) has written a prescription to:

- ☐ 1. limit the amount of protein in the diet prior to the cardiac catheterization.
- ☐ 2. withhold the metformin prior to the cardiac catheterization.

- ☐ 3. administer the metformin with only a sip of water prior to the cardiac catheterization.
- ☐ 4. give the metformin before breakfast.

75. A client with aortic stenosis has increasing dyspnea and dizziness. Identify the area where the nurse would place the stethoscope to assess a -murmur from aortic stenosis.

76. A client is scheduled for a cardiac catheterization. The nurse should do which preprocedure tasks? Select all that apply.

- ☐ 1. Administer all prescribed oral medications.
- ☐ 2. Check for iodine sensitivity.
- ☐ 3. Verify that written consent has been obtained.

- ☐ 4. Withhold food and oral fluids before the procedure.
- ☐ 5. Insert a urinary drainage catheter.

77. Which is the **most** important initial postprocedure nursing assessment for a client who has had a cardiac catheterization?

- ☐ 1. Monitor the laboratory values.
- ☐ 2. Observe neurologic function every 15 minutes.
- ☐ 3. Observe the puncture site for swelling and bleeding.
- ☐ 4. Monitor skin warmth and turgor.

78. A client experiences initial indications of dizziness after having an IV infusion of lidocaine hydrochloride started. The nurse should further assess the client when the client reports having:

- ☐ 1. palpitations.
- ☐ 2. tinnitus.
- ☐ 3. urinary frequency.
- ☐ 4. lethargy.

79. A pulmonary artery catheter is inserted in a client with severe mitral stenosis and regurgitation. The nurse administers furosemide to treat pulmonary congestion and begins a nitroprusside drip as prescribed. The nurse notices a sudden drop in the pulmonary artery diastolic pressure and pulmonary artery wedge pressure. The nurse should **first** assess:

- ☐ 1. 12-lead EKG.
- ☐ 2. blood pressure.
- ☐ 3. lung sounds.
- ☐ 4. urine output.

80. A client has mitral stenosis and will have a valve replacement. The nurse is instructing the client about health maintenance prior to surgery. Inability to follow which prescription would pose the **greatest** health hazard to this client at this time?

- ☐ 1. medication therapy
- ☐ 2. diet modification
- ☐ 3. activity restrictions
- ☐ 4. dental care

81. In preparing the client and the family for a postoperative stay in the intensive care unit (ICU) after open-heart surgery, the nurse should explain that:

- ☐ 1. the client will remain in the ICU for 5 days.
- ☐ 2. the client will sleep most of the time while in the ICU.
- ☐ 3. noise and activity within the ICU are minimal.
- ☐ 4. the client will receive medication to relieve pain.

82. A client who has undergone a mitral valve replacement has had a mediastinal chest tube inserted. The client has persistent bleeding from the sternal incision during the early postoperative period. What actions should the nurse take? Select all that apply.

- ☐ 1. Administer warfarin.
- ☐ 2. Check the postoperative CBC, INR, PTT, and platelet levels.
- ☐ 3. Confirm availability of blood products.
- ☐ 4. Monitor the mediastinal chest tube drainage.
- ☐ 5. Start a dopamine drip for a systolic BP < 100 mm Hg.

83. The **most** effective measure the nurse can use to prevent wound infection when changing a client's dressing after coronary artery bypass surgery is to:

- ☐ 1. observe careful handwashing procedures.
- ☐ 2. clean the incisional area with an antiseptic.
- ☐ 3. use prepackaged sterile dressings to cover the incision.
- ☐ 4. place soiled dressings in a waterproof bag before disposing of them.

84. Which measure should the nurse institute to help prevent complications associated with excessive calcium excretion following cardiac surgery to replace an aortic valve?

- ☐ 1. Ensure a liberal fluid intake.
- ☐ 2. Provide an alkaline-ash diet.
- ☐ 3. Prevent constipation.
- ☐ 4. Enrich the client's diet with dairy products.

85. The nurse should teach the client who is receiving warfarin sodium

that:

- ☐ 1. partial thromboplastin time values determine the dosage of warfarin sodium.
- ☐ 2. protamine sulfate is used to reverse the effects of warfarin sodium.
- ☐ 3. international normalized ratio (INR) is used to assess effectiveness.
- ☐ 4. warfarin sodium will facilitate clotting of the blood.

86. Good dental care is an important measure in reducing the risk of endocarditis. What should a teaching plan to promote good dental care in a client with mitral stenosis instruct the client to do? Select all that apply.

- ☐ 1. Brush the teeth at least twice a day.
- ☐ 2. Avoid use of an electric toothbrush.
- ☐ 3. Take an antibiotic prior to oral surgery.
- ☐ 4. Floss the teeth at least once a day.
- ☐ 5. Have regular dental checkups.
- ☐ 6. Rinse the mouth with an antibiotic mouthwash once a day.

87. Before a client's discharge after mitral valve replacement surgery, the nurse should evaluate the client's understanding of postsurgery activity restrictions. The client should avoid which activity until after the 1-month postdischarge appointment with the surgeon?

- ☐ 1. showering
- ☐ 2. lifting anything heavier than 10 lb (4.5 kg)
- ☐ 3. a program of gradually progressive walking
- ☐ 4. light housework

88. Three days after mitral valve replacement surgery, the client tells the nurse there is a "clicking" noise coming from the chest incision. The nurse's response should reflect the understanding that the client may be experiencing:

- ☐ 1. anxiety related to altered body image.
- ☐ 2. depression related to altered health status.
- ☐ 3. altered tissue perfusion.
- ☐ 4. lack of knowledge regarding the postoperative course.

The Client with Hypertension

89. Metoprolol is added to the pharmacologic therapy of a diabetic female diagnosed with stage 2 hypertension who has been initially treated with furosemide and ramipril. An expected therapeutic effect is:

- ☐ 1. decrease in heart rate.
- ☐ 2. lessening of fatigue.
- ☐ 3. improvement in blood sugar levels.
- ☐ 4. increase in urine output.

90. Which set of postural vital signs (BP in mm Hg and heart rate in beats per minute) indicate inadequate blood volume?

- ☐ 1. Supine 124/76, 88
Sitting 124/74, 92
Standing 122/74, 92
- ☐ 2. Supine 120/70, 70
Sitting 102/64, 86
Standing 100/60, 92
- ☐ 3. Supine 138/86, 74
Sitting 136/84, 80
Standing 134/82, 82
- ☐ 4. Supine 100/70, 72
Sitting 100/68, 74
Standing 98/68, 80

91. A client is taking clonidine for treatment of hypertension. The nurse should teach the client about which common adverse effects of this drug? Select all that apply.

- ☐ 1. dry mouth
- ☐ 2. hyperkalemia
- ☐ 3. impotence
- ☐ 4. pancreatitis
- ☐ 5. sleep disturbance

92. A client with hypertensive emergency is being treated with sodium nitroprusside. In a dilution of 50 mg/250 mL, how many micrograms of sodium nitroprusside are in each milliliter? Round your answer to a whole

number.

mcg.

93. The nurse is discussing medications with a client with hypertension who has a prescription for furosemide daily. The client needs further education when the client states:

- ☐ 1. "I know I should not drive after taking my furosemide."
- ☐ 2. "I should be careful not to stand up too quickly when taking furosemide."
- ☐ 3. "I should take the furosemide in the morning instead of before bed."
- ☐ 4. "I need to be sure to also take the potassium supplement that the doctor prescribed along with my furosemide."

94. In teaching the client with hypertension to avoid orthostatic hypotension, the nurse should teach the client to follow which instructions? Select all that apply.

- ☐ 1. Plan regular times for taking medications.
- ☐ 2. Arise slowly from bed.
- ☐ 3. Avoid standing still for long periods.
- ☐ 4. Avoid excessive alcohol intake.
- ☐ 5. Avoid hot baths.

95. The nurse is teaching a client with hypertension about taking atenolol. The nurse should instruct the client to:

- ☐ 1. avoid sudden discontinuation of the drug.
- ☐ 2. monitor the blood pressure annually.
- ☐ 3. follow a 2-g sodium diet.
- ☐ 4. discontinue the medication if severe headaches develop.

96. The nurse teaches a client who has recently been diagnosed with hypertension about following a low-calorie, low-fat, low-sodium diet. Which of the following menu selections would **best** meet the client's needs?

- ☐ 1. mixed green salad with blue cheese dressing, crackers, and cold cuts
- ☐ 2. ham sandwich on rye bread and an orange
- ☐ 3. baked chicken, an apple, and a slice of white bread

- ☐ 4. hot dogs, baked beans, and celery and carrot sticks

97. A client who has diabetes is taking metoprolol for hypertension. What should the nurse instruct the client to do? Select all that apply.

- ☐ 1. Take the tablets with food at same time each day.
- ☐ 2. Do not crush or chew the tablets.
- ☐ 3. Notify the healthcare provider (HCP) if pulse is 82 beats/min.
- ☐ 4. Have a blood glucose level drawn every 6 to 12 months during therapy.
- ☐ 5. Use an appropriate decongestant if needed.
- ☐ 6. Report any fainting spells to the HCP.

98. A client diagnosed with primary (essential) hypertension is taking chlorothiazide. The nurse determines teaching about this medication is effective when the client makes which statement? “I will: (Select all that apply.)

- ☐ 1. take my weight daily at the same time each day.”
- ☐ 2. not drink alcoholic beverages while on this medication.”
- ☐ 3. reduce salt intake in my diet.”
- ☐ 4. reduce my dosage if I have severe dizziness.”
- ☐ 5. use sunscreen if I have prolonged exposure to sunlight.”
- ☐ 6. take the drug late in the evening.”

99. Which would **most** likely assist the client with hypertension in maintaining an exercise program?

- ☐ 1. Give the client a written exercise program.
- ☐ 2. Explain the exercise program to the client’s spouse.
- ☐ 3. Reassure the client that he or she can do the exercise program.
- ☐ 4. Tailor a program to the client’s needs and abilities.

100. Which would be **most** helpful when coaching a client to stop smoking?

- ☐ 1. Review the negative effects of smoking on the body.
- ☐ 2. Discuss the effects of passive smoking on environmental pollution.
- ☐ 3. Establish the client’s daily smoking pattern.
- ☐ 4. Explain how smoking worsens high blood pressure.

101. When teaching a client about propranolol hydrochloride, the nurse should base the information on the knowledge that propranolol:

- ☐ **1.** blocks beta-adrenergic stimulation and thus causes decreased heart rate, myocardial contractility, and conduction.
- ☐ **2.** increases norepinephrine secretion and thus decreases blood pressure and heart rate.
- ☐ **3.** is a potent arterial and venous vasodilator that reduces peripheral vascular resistance and lowers blood pressure.
- ☐ **4.** is an angiotensin-converting enzyme inhibitor that reduces blood pressure by blocking the conversion of angiotensin I to angiotensin II.

102. What is the **most** important long-term goal for an obese client with hypertension who smokes?

- ☐ **1.** Take medications as prescribed.
- ☐ **2.** Stop smoking.
- ☐ **3.** Make a commitment to long-term lifestyle changes.
- ☐ **4.** Lose weight.

The Client Atrial Fibrillation and Other Dysrhythmias

103. Cardiac telemetry shows that a client who is up to the bathroom has converted from normal sinus rhythm with a rate of 72 beats/min to atrial fibrillation with a ventricular response rate of 100 beats/min. In what order from first to last should the nurse perform these interventions? All options must be used.

1. Assess vital signs.

2. Assist the client to the bed.

3. Initiate intravenous access.

4. Obtain a stat 12-lead electrocardiogram.

104. A client admitted with normal sinus rhythm converts to the following rhythm on the cardiac monitor.

For which symptoms should the nurse assess the client? Select all that apply.

- ☐ 1. carotid bruit
- ☐ 2. light-headedness
- ☐ 3. nausea
- ☐ 4. palpitations
- ☐ 5. shortness of breath
- ☐ 6. systolic murmur

105. A client is admitted to the hospital for evaluation of recurrent episodes of ventricular tachycardia as observed on Holter monitoring. The client is scheduled for electrophysiology studies (EPS) the following morning. Which statement should the nurse include in a teaching plan for this client?

- ☐ 1. "You will continue to take your medications until the morning of the test."
- ☐ 2. "You might be sedated during the procedure and will not remember what has happened."

- ☐ 3. “This test is a noninvasive method of determining the effectiveness of your medication regimen.”
- ☐ 4. “During the procedure, the healthcare provider will insert a special wire to increase the heart rate and produce the irregular beats that caused your signs and symptoms.”

106. During physical assessment, the nurse should further assess the client for signs of atrial fibrillation when palpation of the radial pulse reveals:

- ☐ 1. two regular beats followed by one irregular beat.
- ☐ 2. an irregular rhythm with pulse rate > 100.
- ☐ 3. pulse rate below 60 bpm.
- ☐ 4. a weak, thready pulse.

107. When teaching a client about self-care following placement of a new permanent pacemaker to the left upper chest, the nurse should include which information? Select all that apply.

- ☐ 1. Take and record daily pulse rate.
- ☐ 2. Avoid air travel because of airport security alarms.
- ☐ 3. Immobilize the affected arm for 4 to 6 weeks.
- ☐ 4. Avoid using a microwave oven.
- ☐ 5. Avoid lifting anything heavier than 3 lb (1.36 kg).

108. A client has been admitted to the coronary care unit. The nurse observes third-degree heart block at a rate of 35 bpm on the client’s cardiac monitor. The client has a blood pressure of 90/60 mm Hg. The nurse should first:

- ☐ 1. prepare for transcutaneous pacing.
- ☐ 2. prepare to defibrillate the client at 200 J.
- ☐ 3. administer an IV lidocaine infusion.
- ☐ 4. schedule the operating room for insertion of a permanent pacemaker.

109. A client has atrial fibrillation and a heart rate of 165 bpm. In which order from first to last should the nurse implement these prescriptions? All options must be used.

- 1. Administer oxygen via nasal cannula.

2. Gather supplies for an IV insertion.

3. Place client on a cardiac monitor (ECG).

4. Obtain vital signs including BP, P, R, T, and O₂ saturation.

110. A client is scheduled for the insertion of an implantable cardioverter-defibrillator (ICD). The spouse expresses anxiety about what would happen if the device discharges during physical contact. What should the nurse tell the spouse?

- ☐ 1. Physical contact should be avoided whenever possible.
- ☐ 2. They will not feel the countershock.
- ☐ 3. The shock would feel like a “tingle,” but it would not cause any harm.
- ☐ 4. A warning device sounds before countershock, so there is time to move away.

111. An older adult is admitted to the telemetry unit for placement of a permanent pacemaker because of sinus bradycardia. What is a **priority** goal for the client within 24 hours after insertion of a permanent pacemaker?

- ☐ 1. Maintain skin integrity.
- ☐ 2. Maintain cardiac conduction stability.
- ☐ 3. Decrease cardiac output.
- ☐ 4. Increase activity level.

112. The client who had a permanent pacemaker implanted 2 days earlier

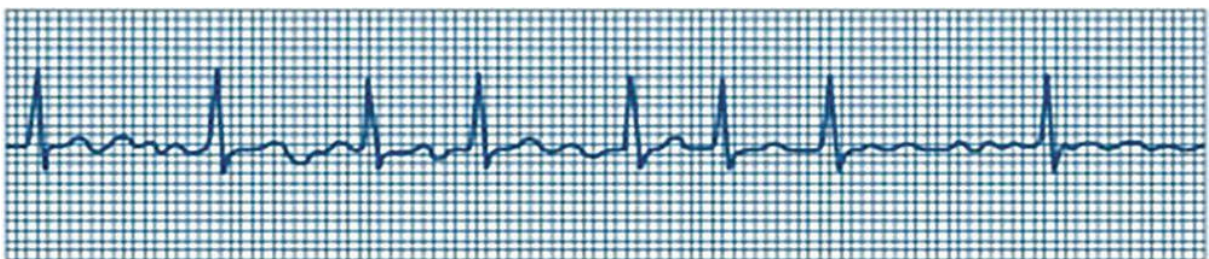

is being discharged from the hospital. The nurse knows that the client understands the discharge plan when the client:

- ☐ 1. selects a low-cholesterol diet to control coronary artery disease.
- ☐ 2. states a need for bed rest for 1 week after discharge.
- ☐ 3. verbalizes safety precautions needed to prevent pacemaker malfunction.
- ☐ 4. explains signs and symptoms of myocardial infarction (MI).

113. An 85-year-old client is admitted to the emergency department (ED) at 2000 hours with syncope, shortness of breath, and reported palpitations (see nurse's notes below). At 2015, the nurse places the client on the ECG monitor and identifies the following rhythm (see below). What should the nurse do? Select all that apply.

Nurse's Progress Notes

Admitted to emergency department	2000
Pulse	150
BP	90/62
Oxygen saturation	92% on room air
RR	22
Progress notes	Client has shortness of breath and states, "My heart is jumping out of my chest and hurts some. I am having trouble catching my breath. I don't want to faint again."
	R. Black, RN

- ☐ 1. Apply oxygen.
- ☐ 2. Prepare to defibrillate the client.
- ☐ 3. Monitor vital signs.
- ☐ 4. Have the client sign consent for cardioversion as prescribed.
- ☐ 5. Teach the client about warfarin treatment and the need for frequent

blood testing.

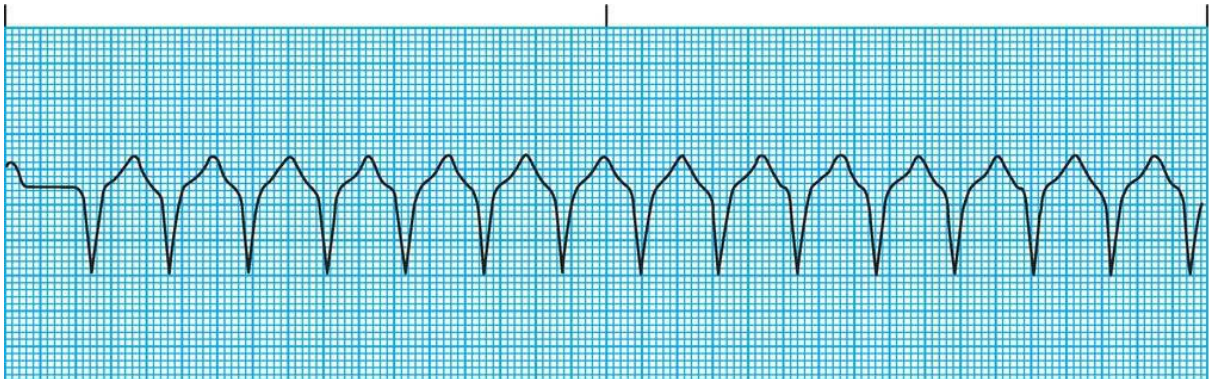

- ☐ 6. Draw blood for a CBC count and thyroid function study.

The Client Requiring Rapid Response or Cardiopulmonary Resuscitation

114. Upon assessment of third-degree heart block on the monitor, what should the nurse do **first**?

- ☐ 1. Call a code.
- ☐ 2. Begin cardiopulmonary resuscitation.
- ☐ 3. Place transcutaneous pacing pads on the client.
- ☐ 4. Prepare for defibrillation.

115. The nurse observes the cardiac rhythm (see below) for a client who is being admitted with a myocardial infarction. What should the nurse do **first**?

- ☐ 1. Prepare for immediate cardioversion.
- ☐ 2. Begin cardiopulmonary resuscitation (CPR).
- ☐ 3. Check for a pulse.
- ☐ 4. Prepare for immediate defibrillation.

116. A client who has been given cardiopulmonary resuscitation (CPR) is transported by ambulance to the hospital's emergency department, where the admitting nurse quickly assesses the client's condition. The **most** effective way to evaluate adequate oxygenation is to determine if:

- ☐ 1. there is a pulse.
- ☐ 2. pupils are reacting to light.
- ☐ 3. mucous membranes are pink.

- ☐ 4. systolic blood pressure is at least 80 mm Hg.

117. A client is given amiodarone in the emergency department for a dysrhythmia. Which finding indicates the drug is having the desired effect?

- ☐ 1. The ventricular rate is increasing.
- ☐ 2. The absent pulse is now palpable.
- ☐ 3. The number of premature ventricular contractions is decreasing.
- ☐ 4. The fine ventricular fibrillation changes to coarse ventricular fibrillation.

118. During cardiopulmonary resuscitation (CPR) for an adult, the rescuer's hands should be placed two fingers' width above the lower end of the sternum. Which organ would be **most** likely at risk for laceration by forceful compressions over the xiphoid process?

- ☐ 1. lung
- ☐ 2. liver
- ☐ 3. stomach
- ☐ 4. diaphragm

119. When performing external chest compressions on an adult during cardiopulmonary resuscitation (CPR), the rescuer should depress the sternum:

- ☐ 1. 0.5 inch (1 cm).
- ☐ 2. 1 inch (2.5 cm).
- ☐ 3. 1.5 inches (4 cm).
- ☐ 4. 2 inches (5 cm).

120. If a client is receiving rescue breaths, and the chest wall fails to rise during cardiopulmonary resuscitation, the rescuer should **first**:

- ☐ 1. try using a bag mask device.
- ☐ 2. decrease the rate of compressions.
- ☐ 3. intubate the client.
- ☐ 4. reposition the airway.

121. During rescue breathing in cardiopulmonary resuscitation (CPR), the victim will exhale by:

- ☐ 1. normal relaxation of the chest.

- ☐ 2. gentle pressure of the rescuer's hand on the upper chest.
- ☐ 3. the pressure of cardiac compressions.
- ☐ 4. turning the head to the side.

122. The rapid response team has been called to manage an unwitnessed cardiac arrest in a client's hospital room. The estimated maximum time a person can be without cardiopulmonary function and still not experience permanent brain damage is:

- ☐ 1. 1 to 2 minutes.
- ☐ 2. 4 to 6 minutes.
- ☐ 3. 8 to 10 minutes.
- ☐ 4. 12 to 15 minutes.

123. A nurse is helping a suspected choking victim. The nurse should perform the Heimlich maneuver when the victim:

- ☐ 1. starts to become cyanotic.
- ☐ 2. cannot speak due to airway obstruction.
- ☐ 3. can make only minimal vocal noises.
- ☐ 4. is coughing vigorously.

124. When performing the Heimlich maneuver on a conscious adult victim, the rescuer delivers inward and upward thrusts specifically:

- ☐ 1. above the umbilicus.
- ☐ 2. at the level of the xiphoid process.
- ☐ 3. over the victim's midabdominal area.
- ☐ 4. below the xiphoid process and above the umbilicus.

125. The monitor technician informs the nurse that the client has started having premature ventricular contractions every other beat. What should the nurse do **first**?

- ☐ 1. Activate the rapid response team.
- ☐ 2. Assess the client's orientation and vital signs.
- ☐ 3. Call the healthcare provider (HCP).
- ☐ 4. Administer a bolus of lidocaine.

126. A client returns to the nursing unit following successful synchronized

cardioversion using transthoracic chest wall patches. The nurse should assess which when the client returns to the room? Select all that apply.

- ☐ 1. vital signs
- ☐ 2. skin of chest wall
- ☐ 3. arterial puncture site
- ☐ 4. level of consciousness
- ☐ 5. cardiac rhythm

127. The nurse is preparing to defibrillate a client on a cardiac monitor who is in ventricular fibrillation (see photo). What should the nurse do?

- ☐ 1. Move the paddle in the nurse's left hand to the midline.
- ☐ 2. Move the paddle in the nurse's right hand to above the client's nipple.
- ☐ 3. Grasp the handles of the paddles to allow visibility of the black markings on the paddle.
- ☐ 4. After pressing the charge button and "calling all clear," push the shock button.

128. The nurse is caring for a client who has become unresponsive, the blood pressure is 80/40 mm Hg, and SpO₂ is 90% on 50% face mask. The nurse should:

- ☐ 1. begin chest compressions.
- ☐ 2. call the rapid response team.
- ☐ 3. remove the family from the room.
- ☐ 4. ventilate the client with a bag mask device.

Managing Care, Quality, and Safety for Clients with Cardiac Health Problems

129. A nurse working the day shift on a cardiac unit receives the following shift report:

1. Client 1: Admitted yesterday morning with hypokalemia. Awaiting repeat electrolyte lab results drawn at 06:00.

2. Client 2: Experienced chest pain at 06:30. Pain resolved after 2 sublingual nitroglycerin tablets.

3. Client 3: Scheduled for oral antihypertensive medications at 0900. Incontinent of urine during the night.

4. Client 4: Scheduled for coronary artery bypass surgery at 0800. The client's family is in the client's room.

At the conclusion of shift report, it is 0730. Put the clients in the order from first to last in which the nurse should plan to assess them. All options must be used.

130. Which activity would be appropriate to delegate to unlicensed assistive personnel (UAP) for a client diagnosed with a myocardial infarction who is stable?

- ☐ 1. Evaluate the lung sounds.
- ☐ 2. Help the client identify risk factors for CAD.
- ☐ 3. Provide teaching on a 2-g sodium diet.
- ☐ 4. Record the intake and output.

131. The unlicensed assistive personnel (UAP) reports to the nurse that a client is “feeling short of breath.” The client’s blood pressure was 124/78 mm Hg 2 hours ago with a heart rate of 82 bpm; the unlicensed assistive personnel reports that blood pressure is now 84/44 mm Hg with a heart rate of 54 bpm, and the client stated, “I just do not feel good.” What actions should the nurse take? Select all that apply.

- ☐ 1. Confirm the client’s vital signs, and complete a quick assessment.
- ☐ 2. Inform the charge nurse of the change in condition, and initiate the hospital’s rapid/emergency response team.
- ☐ 3. Make a quick check on other assigned clients before spending the amount of time required to take care of this client.
- ☐ 4. Position the client in semi-Fowler’s position.
- ☐ 5. Stay with the client, and reassure the client.
- ☐ 6. Call the healthcare provider (HCP), and report the situation using SBAR format.

132. The nurse is assessing a client with heart failure whose blood pressure and weight are being monitored remotely. The nurse reviews data obtained within the last 3 days.

	April 3	April 4	April 5
Weight	160 (72 kg)	162 (73 kg)	165 (74 kg)
Blood Pressure	120/80	130/88	140/90

The nurse calls the client to follow up. The nurse should **first** ask the client:

- ☐ 1. "How are you feeling today?"
- ☐ 2. "Are you having shortness of breath?"
- ☐ 3. "Did you calibrate the scales before using them?"
- ☐ 4. "How much fluid did you drink during the last 24 hours?"

133. The nurse is tracking data on a group of clients with heart failure who have been discharged from the hospital and are being followed at a clinic. Which data are the **best** indicators that nursing interventions of monitoring and teaching have been effective?

- ☐ 1. Ninety percent of clients have not gained weight.
- ☐ 2. Seventy-five percent of the clients viewed the educational DVD.
- ☐ 3. Eighty percent of the clients reported that they are taking their medications.
- ☐ 4. Five percent of the clients required hospitalization in the last 90 days.

134. The nurse in the intensive care unit is giving a report to the nurse in a cardiac step-down unit about a client who had coronary artery bypass surgery. Which is the **most** effective way to assure essential information about the client is reported?

- ☐ 1. Give the report face-to-face with both nurses in a quiet room.
- ☐ 2. Audiotape the report for future reference and documentation.
- ☐ 3. Use a printed checklist with information individualized for the client.
- ☐ 4. Document essential transfer information in the client's medical record.

135. The nurse is planning care for a group of elderly clients who are affected by orthostatic hypotension. What should the nurse do? Select all that

apply.

- ☐ 1. Assist the clients to stand to help prevent falls.
- ☐ 2. Teach clients how to gradually change their position.
- ☐ 3. Request a prescription for antihypertensive medications for clients at high risk.
- ☐ 4. Conduct “fall risk” assessments.
- ☐ 5. Consider the use of sequential compression devices (SCDs) for high-risk clients.
- ☐ 6. Place clients on bed rest.

136. The nurse is caring for a group of clients on a medical-surgical nursing unit. Which task(s) could the nurse delegate to unlicensed assistive personnel (UAP)? Select all that apply.

- ☐ 1. Assess pedal pulses on a client who just returned from a cardiac angiogram.
- ☐ 2. Administer oxygen via nasal cannula to a client with a saturation of 89%.
- ☐ 3. Administer acetaminophen to a client with a pain level of “5” out of “10.”
- ☐ 4. Perform vital signs and oxygen saturation on a client returning from the catheterization lab.
- ☐ 5. Obtain intake and outputs on a client experiencing heart failure.

Answers, Rationales, and Test-Taking Strategies

*The answers and the rationales for each question follow below, along with keys (🔑) to the client need (CN) and cognitive level (CL) for each question. In addition, you will also see a glossary icon (📖) highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 12–23 and pages 35–36 in Part 1 of this book.*

The Client with Acute Coronary Syndromes

1. 2. To best monitor that the client's circulation remains intact, the dorsal surface of the right foot should be palpated. When the left side of the heart is catheterized, the cannula enters via an artery. In this instance, the right femoral artery was accessed. While all options assess arterial points of the right leg, the dorsal surface of the right foot (the pedal pulse) is the most distal. If this pulse point is present and unchanged from before the procedure, the other pulse points should also be intact.

 CN: Physiological adaptation; CL: Apply

2. 4. The elevated troponin level should be reported to the HCP  prior to the stress test as this change indicates myocardial damage. Sending the client to walk on a treadmill for stress testing would be contraindicated with evidence of recent myocardial injury and could further extend the damage. The other blood levels are helpful but not critical to this client's welfare at this point in time.

 CN: Reduction of risk potential; CL: Analyze

3. 4. Nursing management for a client with a myocardial infarction should focus on pain management and decreasing myocardial oxygen demand. Fluid status should be closely monitored. Client education should begin once the client is stable and amenable to teaching. Visitation should be based on client comfort and maintaining a calm environment.

 CN: Physiological adaptation; CL: Synthesize

4. 2. Nitroglycerin is a vasodilator that will lower blood pressure. The client is having chest pain, and the ST elevation indicates injury to the myocardium, which may benefit from nitroglycerin. The potassium and heart rate are within normal range.

 CN: Pharmacological and parenteral therapies; CL: Analyze

5. 1. The nurse should first obtain vital signs as changes in the vital signs will reflect the severity of the sudden drop in cardiac output: decrease in blood pressure, increase in heart rate, and increase in respirations. Infarction of the papillary muscles is a potential complication of an MI causing

ineffective closure of the mitral valve during systole. Mitral regurgitation results when the left ventricle contracts and blood flows backward into the left atrium, which is heard at the fifth intercostal space, left midclavicular line. The murmur worsens during expiration and in the supine or left-side position and can best be heard when the client is in these positions, not with the client leaning forward. A 12-lead ECG views the electrical activity of the heart; an echocardiogram views valve function.

CN: Physiological adaptation; CL: Synthesize

6. 1,4,5. Morphine sulfate acts as an analgesic and sedative. It also reduces myocardial oxygen consumption, blood pressure, and heart rate. Morphine also reduces anxiety and fear due to its sedative effects and by slowing the heart rate. It can depress respirations; however, such an effect may lead to hypoxia, which should be avoided in the treatment of chest pain. Angiotensin-converting enzyme inhibitor drugs, not morphine, may help to prevent ventricular remodeling.

CN: Pharmacological and parenteral therapies; CL: Evaluate

7. 24 mL/h

First, calculate how many units are in each milliliter of the medication:

$$\frac{25,000 \text{ units}}{500 \text{ mL}} = \frac{50 \text{ units}}{1 \text{ mL}}$$

Next, calculate how many milliliters the client receives per hour:

$$\frac{1,200 \text{ units}}{1 \text{ hour}} \div \frac{50 \text{ units}}{1 \text{ mL}}$$

$$= \frac{24}{1} \times \frac{1 \text{ mL}}{1} = 24 \text{ mL/h}$$

 CN: Pharmacological and parenteral therapies; CL: Apply

8. 1. The client is having symptoms of a myocardial infarction. The first action is to prevent platelet formation and block prostaglandin synthesis. The client should place the tablet under the tongue and wait until it is absorbed. Nitroglycerin tablets are not effective if chewed, swallowed, or placed between the cheek and gums.

 CN: Physiological adaptation; CL: Apply

9. 2. A low urine output and confusion are signs of decreased tissue perfusion. Orthopnea is a sign of left-sided heart failure. Crackles, edema, and weight gain should be monitored closely, but the levels are not as high a priority. With atrial fibrillation, there is a loss of atrial kick, but the blood pressure and heart rate are stable.

 CN: Physiological adaptation; CL: Analyze

10. 4. The nurse should first assess the client's tolerance to the drop in heart rate by checking the blood pressure and level of consciousness and - determine if atropine is needed. If the client is symptomatic, atropine and transcutaneous pacing are interventions for symptomatic bradycardia. Once the client is stable, further physical assessments can be done.

 CN: Physiological adaptation; CL: Synthesize

11. 1,2,3,4. When preparing the client for a cardiac angiogram, the nurse should determine if the client has an allergy to the liquid contrast medium

used in the procedure. Contrast dyes contain iodine, and the administration of a dye could lead to an anaphylactic response in clients who are allergic to the dye. An intravenous infusion will be started before the procedure to administer the contrast dye. The client should not eat or drink for 8 hours prior to the procedure. The client may experience a flushing sensation, but this is a normal response and does not indicate a life-threatening reaction. The client may receive light sedation, but not an anesthetic as the client must be awake to follow instructions. The client should be instructed to remain still during the procedure.

CN: Reduction of risk potential; CL: Apply

12. 1. An S_3 heart sound occurs early in diastole as the mitral and tricuspid valves open and blood rushes into the ventricles. To distinguish an S_3 from a physiologic S_2 split, a split S_2 occurs during inspiration and S_3 remains constant during the respiratory cycle. Its pitch is softer and best heard with the bell at the apex, and it is one of the first clinical findings in left ventricular failure. An S_4 is heard in late diastole when atrial contraction pumps volume into a stiff, noncompliant ventricle. An S_4 is not heard in a client with atrial fibrillation because there is no atrial contraction. Murmurs are sounds created by turbulent blood flow through an incompetent or stenotic valve.

CN: Physiological adaptation; CL: Analyze

13. 1. Although obtaining the ECG, chest radiograph, and blood work are all important, the nurse's priority action should be to relieve the crushing chest pain. Therefore, administering morphine sulfate is the priority action.

CN: Physiological adaptation; CL: Synthesize

14. 2. All of the 1200 hour assessments are signs of decreased cardiac output and can be an ominous sign in a client who has recently experienced an MI; the nurse should notify the **HCP** 📖 of these changes. Cardiac output and blood pressure may continue to fall to dangerous levels, which can induce further coronary ischemia and extension of the infarct. While the client is currently hypotensive, giving a fluid challenge/bolus can precipitate increased workload on a damaged heart and extend the myocardial infarction.

Exercise or walking for this client will increase both the heart rate and stroke volume, both of which will increase cardiac output, but the increased cardiac output will increase oxygen needs especially in the heart muscle and can induce further coronary ischemia and extension of the infarct. The client is hypotensive. Although the client has decreased urinary output, this is the body's response to a decreasing cardiac output, and it is not appropriate to administer furosemide.

CN: Physiological adaptation; CL: Synthesize

15. 2. Thrombolytic drugs are administered within the first 6 hours after onset of an MI to lyse clots and reduce the extent of myocardial damage.

CN: Pharmacological and parenteral therapies; CL: Evaluate

16. 3. The client is experiencing a single PVC. PVCs are characterized by a QRS of longer than 0.12 second and by a wide, notched, or slurred QRS complex. There is no P wave related to the QRS complex, and the T wave is usually inverted. PVCs are potentially serious and can lead to ventricular fibrillation or cardiac arrest when they occur more than 6 to 10 in an hour in clients with myocardial infarction. The nurse should continue to monitor the client and note if the PVCs are increasing. It is not necessary to notify the **HCP**  or call the **rapid response team**  at this point. Lidocaine is not indicated from the data on this ECG.

CN: Reduction of risk potential; CL: Synthesize

17. 1. The nurse should first don gloves and apply direct pressure over the site to stop blood loss from the femoral artery. While the nurse will later observe the site for further bleeding and record the extent of bleeding, this is not the first action that is needed. If the bleeding cannot be controlled, the healthcare provider who performed the procedure should be contacted, but first, an attempt to manually stop the bleeding with direct pressure is warranted. Protamine sulfate is the antidote for heparin sodium, but this is not an initial action to control the bleeding.

CN: Reduction of risk potential. CL: Synthesize

18. 2. Metoprolol is indicated in the treatment of hemodynamically stable clients with an acute MI to reduce cardiovascular mortality. Cardiogenic

shock causes severe hemodynamic instability, and a beta-blocker will further depress myocardial contractility. The metoprolol should be discontinued. The decrease in cardiac output will impair perfusion to the kidneys. Cardiac output, hemodynamic measurements, and appropriate interventions can be determined with a PA catheter. Dobutamine will improve contractility and increase the cardiac output that is depressed in cardiogenic shock.

CN: Physiological adaptation; CL: Synthesize

19. 1. Oliguria occurs during cardiogenic shock because there is reduced blood flow to the kidneys. Typical signs of cardiogenic shock include low blood pressure, rapid and weak pulse, decreased urine output, and signs of diminished blood flow to the brain, such as confusion and restlessness. Cardiogenic shock is a serious complication of MI, with a mortality rate approaching 90%. Fever is not a typical sign of cardiogenic shock. The other changes in vital signs on the client's chart are not as significant as the decreased urinary output.

CN: Reduction of risk potential; CL: Analyze

20. 1. IV nitroglycerin infusion requires an infusion pump for precise control of the medication. Blood pressure monitoring would be done with a continuous system and more frequently than every 4 hours. Hourly urine outputs are not always required. Obtaining serum potassium levels is not associated with nitroglycerin infusion.

CN: Pharmacological and parenteral therapies; CL: Synthesize

21. 3,4,2,1. The nurse should first connect the client to the monitor by attaching the electrodes. Electrocardiography can be used to identify myocardial ischemia and infarction, rhythm and conduction disturbances, chamber enlargement, electrolyte imbalances, and the effects of drugs on the client's heart. The nurse next obtains vital signs to establish a baseline. Next, the nurse should administer the morphine; morphine is the drug of choice in relieving myocardial infarction (MI) pain; it may cause a transient decrease in blood pressure. When the client is stable, the nurse can obtain a history of the client's drug use.

CN: Reduction of risk potential; CL: Synthesize

22. 2,5. It is important for clients to wear hearing aids to this procedure so that they can hear the questions posed to them by the healthcare team. Chest pain often occurs when the balloon within the stent is inflated and deployed into the coronary artery. It is expected and brief but should still be reported by the client. During the procedure and for a prescribed amount of time after the procedure, the client will need to remain flat in bed with the right leg straight, not flexed, to prevent bleeding from the access site. The site is not routinely stitched. It is a puncture rather than an incision requiring sutures. The client may be given intravenous medication to help with comfort, but the client is kept awake to answer questions and to hear instructions and explanations. General anesthesia is not given.

CN: Reduction of risk potential; CL: Create

23. 4. Sinus tachycardia is characterized by normal conduction and a regular rhythm, but with a rate exceeding 100 bpm. A P wave precedes each QRS, and the QRS is usually normal.

CN: Reduction of risk potential; CL: Analyze

24. 2. PVCs are often a precursor of life-threatening arrhythmias, including ventricular tachycardia and ventricular fibrillation. An occasional PVC is not considered dangerous, but if PVCs occur at a rate greater than five or six per minute in the post-MI client, the **HCP**  should be notified immediately. More than six PVCs per minute is considered serious and usually calls for decreasing ventricular irritability by administering medications such as lidocaine hydrochloride. Increasing the IV infusion rate would not decrease the number of PVCs. Increasing the oxygen concentration should not be the nurse's first course of action; rather, the nurse should notify the HCP promptly. Administering a prescribed analgesic would not decrease ventricular irritability.

CN: Physiological adaptation; CL: Synthesize

25. 4. By day 2 of hospitalization after an MI, clients are expected to be able to perform personal care without chest pain. Severe chest pain should not be present on day 2 after an MI. Day 2 of hospitalization may be too soon for clients to be able to identify risk factors for MI or to begin a walking program; however, the client may be sitting up in a chair as part of the

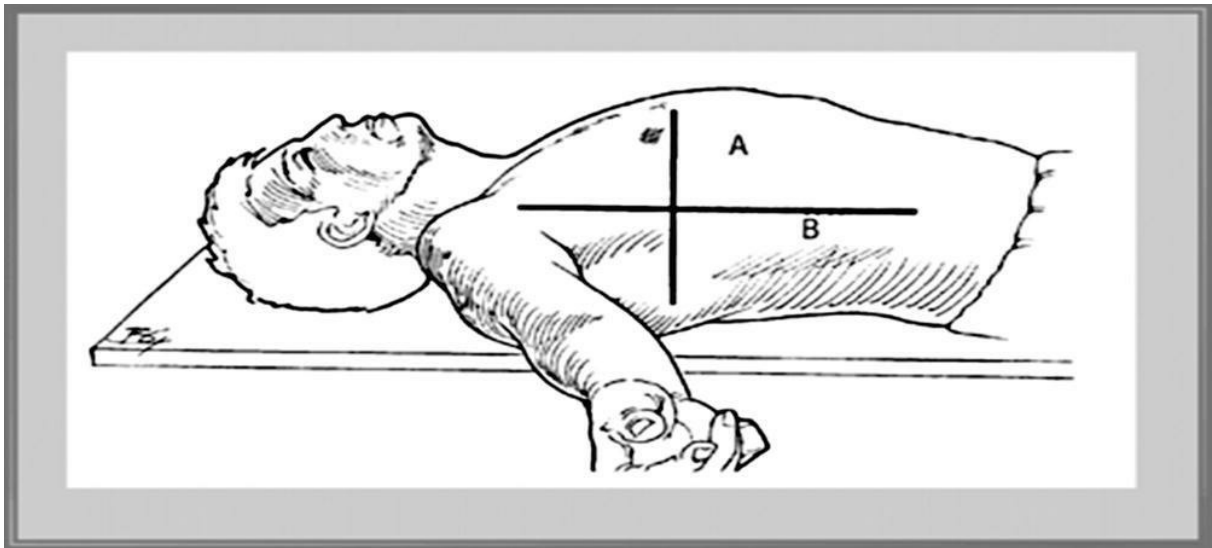

cardiac rehabilitation program.

 CN: Physiological adaptation; CL: Evaluate

26. 2. Furosemide is a loop diuretic that acts to increase urine output. Furosemide does not increase blood pressure, decrease pain, or decrease arrhythmias.

 CN: Pharmacological and parenteral therapies; CL: Evaluate

27.

Correct location: The zero point on the CVP transducer needs to be at the level of the right atrium. The right atrium is located at the midaxillary line at the fourth intercostal space. The phlebostatic axis is determined by drawing an imaginary vertical line from the fourth intercostal space at the sternal border to the right side of the chest (A). A secondary imaginary line is drawn horizontally at the level of the midpoint between the anterior and posterior surfaces of the chest (B). The phlebostatic axis is located at the intersection of points A and B.

 CN: Physiologic adaptation; CL: Apply

28. 3. When wedged, the catheter is “pointing” indirectly at the left end-diastolic pressure. The pulmonary artery wedge pressure is measured when the tip of the catheter is slowly inflated and allowed to wedge into a branch of the pulmonary artery. Once the balloon is wedged, the catheter reads the pressure in front of the balloon. During diastole, the mitral valve is open,

reflecting left ventricular end-diastolic pressure. Cardiac output is the amount of blood ejected by the heart in 1 minute and is determined through thermodilution and not wedge pressure. Cardiac index is calculated by dividing the client's cardiac output by the client's body surface area and is considered a more accurate reflection of the individual client's cardiac output. Right atrial blood pressure is not measured with the pulmonary artery catheter.

CN: Physiologic adaptation; CL: Apply

29. 3. Encouraging the client to move the legs while in bed is a preventive strategy taught to all clients who are hospitalized and on bed rest to promote venous return. The muscular action aids in venous return and prevents venous stasis in the lower extremities. These exercises are not intended to prepare the client for ambulation. These exercises are not associated with promoting urinary and intestinal elimination. These exercises are not performed to decrease the risk of pressure ulcer formation.

CN: Physiological adaptation; CL: Apply

30. 2. Recommended dietary principles in the acute phase of MI include avoiding large meals because small, easily digested foods are better tolerated. Fluids are given according to the client's needs, and sodium restrictions may be prescribed, especially for clients with manifestations of heart failure. Cholesterol restrictions may be prescribed as well. Clients are not prescribed diets of liquids only or restricted to nothing by mouth unless their condition is very unstable.

CN: Physiological adaptation; CL: Apply

31. 1,3,4. Clopidogrel is generally well absorbed and may be taken with or without food; it should be taken at the same time every day, and, while food may help prevent potential GI upset, food has no effect on absorption of the drug. Bleeding is the most common adverse effect of clopidogrel; the client must understand the importance of reporting any unexpected, prolonged, or excessive bleeding including blood in urine or stool. Increased bruising and bleeding gums are possible side effects of clopidogrel; the client should be aware of this possibility. Plavix is an antiplatelet agent used to prevent clot formation in clients that have experienced or are at risk for myocardial

infarction, ischemic stroke, peripheral artery disease, or acute coronary syndrome. It is not necessary to drink a glass of water after taking clopidogrel.

CN: Pharmacological and parenteral therapies; CL: Create

32. 4. The woman who is 65 years old, is overweight, and has an elevated LDL is at greatest risk. Total cholesterol >200 (11.1 mmol/L), LDL >100 (5.5 mmol/L), HDL <40 (2.2 mmol/L) in men, HDL <50 (2.8 mmol/L) in women, men 45 years and older, women 55 years and older, smoking, and obesity increase the risk of CAD. Atorvastatin reduces LDL and decreases risk of CAD. The combination of postmenopausal, obesity, and high LDL places this client at greatest risk.

CN: Health promotion and maintenance; CL: Analyze

33. 1. Nitroglycerin acts to decrease myocardial oxygen consumption. Vasodilation makes it easier for the heart to eject blood, resulting in decreased oxygen needs. Decreased oxygen demand reduces pain caused by heart muscle not receiving sufficient oxygen. While blood pressure may decrease ever so slightly due to the vasodilation effects of nitroglycerin, it is only secondary and not related to the angina the client is experiencing. Increased blood pressure would mean the heart would work harder, increasing oxygen demand and thus angina. Decreased heart rate is not an effect of nitroglycerin.

CN: Pharmacological and parenteral therapy; CL: Evaluate

34. 3. In health coaching, unlike traditional client education techniques in which the nurse provides information, the goal of coaching is to encourage the client to explore the reasons for the behavior and establish a vision for health behavior and the way he or she can make changes to improve their health behavior and reduce or eliminate health risks. When coaching a client, the nurse does not provide information, withhold praise, or instill fear.

CN: Psychosocial integrity; CL: Synthesize

35. 4. The thrombolytic agent t-PA, administered intravenously, lyses the clot blocking the coronary artery. The drug is most effective when administered within the first 6 hours after onset of MI. The drug does not

reduce coronary artery vasospasm; nitrates are used to promote vasodilation. Arrhythmias are managed by antiarrhythmic drugs. Surgical approaches are used to open the coronary artery and re-establish a blood supply to the area.

CN: Pharmacological and parenteral therapies; CL: Apply

36. 1. Cardiac arrhythmias are commonly observed with administration of t-PA. Cardiac arrhythmias are associated with reperfusion of the cardiac tissue. Hypotension is commonly observed with administration of t-PA. Seizures and hypothermia are not generally associated with reperfusion of the cardiac tissue.

CN: Reduction of risk potential; CL: Synthesize

37. 2. A history of cerebral hemorrhage is a contraindication to administration of t-PA because the risk of hemorrhage may be further increased. Age > 60 years, history of heart failure, and cigarette smoking are not contraindications.

CN: Pharmacological and parenteral therapies; CL: Apply

38. 2. Advanced cardiac life support recommends that at least one or two IV lines be inserted in one or both of the antecubital spaces. Calling the **HCP** , obtaining a portable chest radiograph, and drawing blood for the laboratory are important but secondary to starting the IV line.

CN: Physiological adaptation; CL: Synthesize

39. 1. Further assessment is needed in this situation. It is premature to initiate other actions until further data have been gathered. Inquiring about the onset, duration, location, severity, and precipitating factors of the chest heaviness will provide pertinent information to convey to the **HCP** .

CN: Reduction of risk potential; CL: Synthesize

40. 3. Nitroglycerin may be used prophylactically before stressful physical activities such as stair climbing to help the client remain pain free. Climbing the stairs early in the day would have no impact on decreasing pain episodes. Resting before or after an activity is not as likely to help prevent an activity-related pain episode.

CN: Reduction of risk potential; CL: Synthesize

41. 3. Pasta, tomato sauce, salad, and coffee would be the best selection for the client following a low-cholesterol diet. Hamburgers, milk shakes, liver, and fried foods tend to be high in cholesterol.

CN: Basic care and comfort; CL: Apply

42. 1. The client should report a change in the pattern of chest pain. It may indicate increasing severity of coronary artery disease. Pain occurring during stress or sexual activity would not be unexpected, and the client may be instructed to take nitroglycerin to prevent this pain. Pain during or after an activity such as lawn mowing also would not be unexpected; the client may be instructed to take nitroglycerin to prevent this pain or may be restricted from doing such activities.

CN: Reduction of risk potential; CL: Apply

43. 2. Cardiac catheterization is done in clients with angina primarily to assess the extent and the severity of the coronary artery blockage. A decision about medical management, angioplasty, or coronary artery bypass surgery will be based on the catheterization results. Coronary bypass surgery would be used to bypass obstructed vessels. Although cardiac catheterization can be used to assess the functional adequacy of the valves and heart muscle, in this case the client has unstable angina and therefore would need the procedure to assess the extent of arterial blockage.

CN: Reduction of risk potential; CL: Apply

44. 1,2,4,3. When a client returns from having a transluminal balloon angioplasty with femoral access, the nurse should first obtain baseline vital signs and oxygen saturation to determine evidence of bleeding or decreased tissue perfusion. The nurse should next assess the pedal pulses to determine if the client has adequate peripheral tissue perfusion. Next the nurse should inspect the catheterization site and then determine color and sensation in the affected leg.

CN: Physiologic integrity; CL: Analyze

45. 2. Late onset of puberty is not generally considered to be a risk factor for the development of atherosclerosis. Risk factors for atherosclerosis include family history of atherosclerosis, cigarette smoking, hypertension,

high blood cholesterol level, male gender, diabetes mellitus, obesity, and physical inactivity.

CN: Physiological adaptation; CL: Apply

46. 3. Nitroglycerin produces peripheral vasodilation, which reduces myocardial oxygen consumption and demand. Vasodilation in coronary arteries and collateral vessels may also increase blood flow to the ischemic areas of the heart. Nitroglycerin decreases myocardial oxygen demand. Nitroglycerin does not have an effect on pericardial spasticity or conductivity in the myocardium.

CN: Pharmacological and parenteral therapies; CL: Apply

47. 1. Headache is a common side effect of nitroglycerin that can be alleviated with aspirin, acetaminophen, or ibuprofen. The sublingual nitroglycerin needs to be absorbed in the mouth, which will be disrupted with drinking. Lying flat will increase blood flow to the head and may increase pain and exacerbate other symptoms, such as shortness of breath.

CN: Physiological adaptation; CL: Synthesize

48. 4. The nurse should instruct the client that correct protocol for using sublingual nitroglycerin involves immediate administration when chest pain occurs. Sublingual nitroglycerin appears in the bloodstream within 2 to 3 minutes and is metabolized within about 10 minutes. The client should sit down and place the tablet under the tongue. If the chest pain is not relieved within 5 minutes, the client should call 911. Although some **healthcare providers (HCPs)**  may recommend taking a second or third tablet spaced 5 minutes apart and then calling for emergency assistance, it is not appropriate to take two tablets at once. Nitroglycerin acts within 2 to 3 minutes, and the client should not wait 15 minutes to take further action. The client should call 911 to obtain emergency help rather than calling the HCP.

CN: Pharmacological and parenteral therapies; CL: Synthesize

49. 3. The client taking nifedipine should inspect the gums daily to monitor for gingival hyperplasia. This is an uncommon adverse effect but one that requires monitoring and intervention if it occurs. The client taking nifedipine might be taught to monitor blood pressure, but more often than

monthly. These clients would not generally need to perform daily weights or limit intake of green leafy vegetables.

CN: Pharmacological and parenteral therapies; CL: Synthesize

50. 2,5,6. Simvastatin is used in combination with diet and exercise to decrease elevated total cholesterol. The client should take simvastatin in the evening, and the nurse should instruct the client that if a dose is missed, to take it as soon as remembered, but not to take at the same time as the next scheduled dose. It is not necessary to take the pill with food. The client does not need to limit greens (limiting greens is appropriate for clients taking warfarin), but the nurse should instruct the client to avoid grapefruit and grapefruit juice, which can increase the amount of the drug in the bloodstream. A serious side effect is myopathy, and the client should report muscle pain or tenderness to the **healthcare provider (HCP)** 📖.

CN: Pharmacology; CL: Create

The Client with Heart Failure

51. 3. The nurse should withhold the dose of captopril; captopril is an ACE inhibitor, and a side effect of the medication is hyperkalemia. The BUN and creatinine, which are normal, should be viewed prior to administration since renal insufficiency is another potential side effect of an ACE-I. The heart rate is within normal limits. The nurse should question the dose of metoprolol if the client's heart rate is bradycardic. The hemoglobin and hematocrit are normal for a female. The nurse should report the high potassium level and that the captopril was withheld.

CN: Pharmacological and parenteral therapies; CL: Synthesize

52. 3. Warfarin is an anticoagulant, which is used in the treatment of atrial fibrillation and decreased left ventricular ejection fraction (<20%) to prevent thrombus formation and release of emboli into the circulation. The client may also take other medication as needed to manage the heart failure. Warfarin does not reduce circulatory load or improve myocardial workload. Warfarin does not affect cardiac rhythm.

CN: Reduction of risk potential; CL: Evaluate

53. 2. Early symptoms of digoxin toxicity include anorexia, nausea, and vomiting. Visual disturbances can also occur, including double or blurred vision and visual halos. Hypokalemia is a common cause of digoxin toxicity associated with arrhythmias because low serum potassium can enhance ectopic pacemaker activity. Although vomiting can lead to fluid deficit, given the client's history, the vomiting is likely due to the adverse effects of digoxin toxicity. Pulmonary edema is manifested by dyspnea and coughing.

CN: Pharmacological and parenteral therapies; CL: Analyze

54. 1,3,5,6. Dyspnea, crackles, oliguria, and decreased oxygen saturation are signs and symptoms related to pulmonary congestion and inadequate tissue perfusion associated with left-sided heart failure. JVD and right upper quadrant pain along with ascites and edema are usually associated with congestion of the peripheral tissues and viscera in right-sided heart failure.

CN: Physiological adaptation; CL: Apply

55. 4,5. Signs of pulmonary edema are identical to those of acute heart failure. Signs and symptoms are generally apparent in the respiratory system and include coarse crackles, severe dyspnea, and tachypnea. Severe tachycardia occurs due to sympathetic stimulation in the presence of hypoxemia. Blood pressure may be decreased or elevated, depending on the severity of the edema. Jugular vein distention, dependent edema, and anorexia are symptoms of right-sided heart failure.

CN: Physiological adaptation; CL: Analyze

56. 1. It is a priority to assess blood pressure first because people with pulmonary edema typically experience severe hypertension that requires early intervention. The client probably does not have skin breakdown, but when the client is stable and when the nurse obtains a complete health history, the nurse should inspect the client's skin for any signs of breakdown; however, when the client is stable, the nurse should inspect the skin. Potassium levels are not the first priority. The nurse should monitor urine output after the client is stable.

CN: Reduction of risk potential; CL: Analyze

57. 1,4,6. It is not unusual for the elderly client to become somewhat

confused when “relocated” to the hospital, and this may be more difficult for those with known dementia. Frequent reorientation delivered patiently and calmly along with placing familiar items nearby so the client can see them may help decrease confusion related to hospitalization. Establishing a trusting relationship is important with every client but may be more so with this client. Putting the client in a room further from the nursing station may decrease extra noise for the client but will also make it more difficult to observe the client and maintain a safe environment. Procedures should be explained to the client prior to proceeding and should not be rushed. Visits by family and friends may help to keep the client oriented.

CN: Basic care and comfort; CL: Synthesize

58. 1,2,3,5. Heart failure can be a result of several cardiovascular conditions, which will affect the heart’s ability to pump effectively. The body attempts to compensate through several neurohormonal mechanisms. Decreased cardiac output stimulates the aortic and carotid baroreceptors, which activates the sympathetic nervous system to release norepinephrine and epinephrine. This early response increases the heart rate and contractility. It also has some negative effects, including vasoconstriction of the skin, GI tract, and kidneys. Decreased renal perfusion (due to low CO and vasoconstriction) activates the renin-angiotensin-aldosterone process resulting in the release of antidiuretic hormone. This causes fluid retention in an attempt to increase blood pressure and, therefore, cardiac output. In the damaged heart, this causes fluid overload. There is no parasympathetic response. Decreased pulmonary perfusion can be a result of fluid overload or concomitant pulmonary disease.

CN: Physiologic adaptation; CL: Analyze

59. 4 mL. Desired amount (D) divided by what is available (H) times quantity (Q) = amount to administer. $D = 40 \text{ mg}$ divided by $H = 10 \text{ mg/mL}$ equals 40 divided by $10 = 4 \text{ mL}$.

CN: Pharmacological and parenteral therapies; CL: Apply

60. 3. Sitting almost upright in bed with the feet and legs resting on the mattress decreases venous return to the heart, thus reducing myocardial workload. Also, the sitting position allows maximum space for lung

expansion. Low Fowler's position would be used if the client could not tolerate high Fowler's position for some reason. Lying on the right side would not be a good position for the client in heart failure. The client in heart failure would not tolerate Trendelenburg's position.

CN: Reduction of risk potential; CL: Synthesize

61. 1. Increasing cardiac output is the main goal of therapy for the client with heart failure or pulmonary edema. Pulmonary edema is an acute medical emergency requiring immediate intervention. Respiratory status and comfort will be improved when cardiac output increases to an acceptable level. Peripheral edema is not typically associated with pulmonary edema.

CN: Reduction of risk potential; CL: Apply

62. 2. Digoxin is a cardiac glycoside with positive inotropic activity. This inotropic activity causes increased strength of myocardial contractions and thereby increases output of blood from the left ventricle. Digoxin does not dilate coronary arteries. Although digoxin can be used to treat arrhythmias and does decrease the electrical conductivity of the myocardium, these are not primary reasons for its use in clients with heart failure and pulmonary edema.

CN: Pharmacological and parenteral therapies; CL: Evaluate

63. 1. After intravenous injection of furosemide, diuresis normally begins in about 5 minutes and reaches its peak within about 30 minutes. Medication effects last 2 to 4 hours. When furosemide is given intramuscularly or orally, drug action begins more slowly and lasts longer than when it is given intravenously.

CN: Pharmacological and parenteral therapies; CL: Evaluate

64. 4. When diuretics are given early in the day, the client will void frequently during the daytime hours and will not need to void frequently during the night. Therefore, the client's sleep will not be disturbed. Taking furosemide in the morning has no effect on preventing electrolyte imbalances or retarding rapid drug absorption. The client should not accumulate excessive fluids throughout the night.

CN: Pharmacological and parenteral therapies; CL: Apply

65. 3. Colored vision and seeing yellow spots are symptoms of digoxin toxicity. Abdominal pain, anorexia, nausea, and vomiting are other common symptoms of digoxin toxicity. Additional signs of toxicity include arrhythmias, such as atrial fibrillation or bradycardia. Rash, increased appetite, and elevated blood pressure are not associated with digoxin toxicity.

CN: Pharmacological and parenteral therapies; CL: Apply

66. 4. A low serum potassium level (hypokalemia) predisposes the client to digoxin toxicity. Because potassium inhibits cardiac excitability, a low serum potassium level would mean that the client would be prone to increased cardiac excitability. Sodium, glucose, and calcium levels do not affect digoxin or contribute to digoxin toxicity.

CN: Pharmacological and parenteral therapies; CL: Analyze

67. 2. Canned foods and juices such as tomato juice are typically high in sodium and should be avoided in a sodium-restricted diet. Canned foods and juices in which sodium has been removed or limited are available. The client should be taught to read labels carefully. Apples and whole wheat breads are not high in sodium. Beef tenderloin would have less sodium than canned foods or tomato juice.

CN: Reduction of risk potential; CL: Apply

68. 2,3,4. Hypokalemia is a side effect of loop diuretics. Bananas, dried fruit, and oranges are examples of food high in potassium. Angel food cake and peppers are low in potassium.

CN: Pharmacological and parenteral therapies; CL: Apply

69. 2. A normal apical impulse is found over the apex of the heart and is typically located and auscultated in the left fifth intercostal space in the midclavicular line. An apical impulse located or auscultated below the fifth intercostal space or lateral to the midclavicular line may indicate left ventricular enlargement.

CN: Physiological adaptation; CL: Analyze

70. 1. The ankle edema suggests fluid volume overload. The nurse should assess respiratory rate, lung sounds, and SpO₂ to identify any signs of

respiratory symptoms of heart failure requiring immediate attention. The nurse can then draw blood for laboratory studies, insert the Foley catheter, and weigh the client.

CN: Physiological adaptation; CL: Synthesize

71. 3. Heart failure is a complex and chronic condition. Education should focus on health promotion and preventive care in the home environment. Signs and symptoms can be monitored by the client. Instructing the client to obtain daily weights at the same time each day is very important. The client should be told to call the **healthcare provider (HCP)**  if there has been a weight gain of 2 lb (0.91 kg) or more. This may indicate fluid overload, and treatment can be prescribed early and on an outpatient basis, rather than waiting until the symptoms become life threatening. Following a high-fiber diet is beneficial, but it is not relevant to the teaching needs of the client with heart failure. Prescribing an exercise program for the client, such as walking 2 miles (3.2 km) every day, would not be appropriate at discharge. The client's exercise program would need to be planned in consultation with the HCP and based on the history and the physical condition of the client. The client may require exercise tolerance testing before an exercise plan is laid out. Although the nurse does not prescribe an exercise program for the client, a sedentary lifestyle should not be recommended.

CN: Reduction of risk potential; CL: Create

72. 1,2,4. If the client will call the **healthcare provider (HCP)**  when there is increasing shortness of breath, weight gain over 2 lb (0.9 kg) in 1 day, and need to sleep sitting up, this indicates an understanding of the teaching because these signs and symptoms suggest worsening of the client's heart failure. Although the client will most likely be placed on a sodium-restricted diet, the client would not need to notify the HCP if he or she had consumed a high-sodium breakfast. Instead, the client would need to be alert for possible signs and symptoms of worsening heart failure and work to reduce sodium intake for the rest of that day and in the future.

CN: Reduction of risk potential; CL: Evaluate

The Client with Valvular Heart Disease

73. 3. A complication of balloon valvuloplasty is emboli resulting in a stroke. The client's increased drowsiness should be evaluated. Some degree of mitral regurgitation is common after the procedure. The oxygen status and urine output should be monitored closely but do not warrant concern.

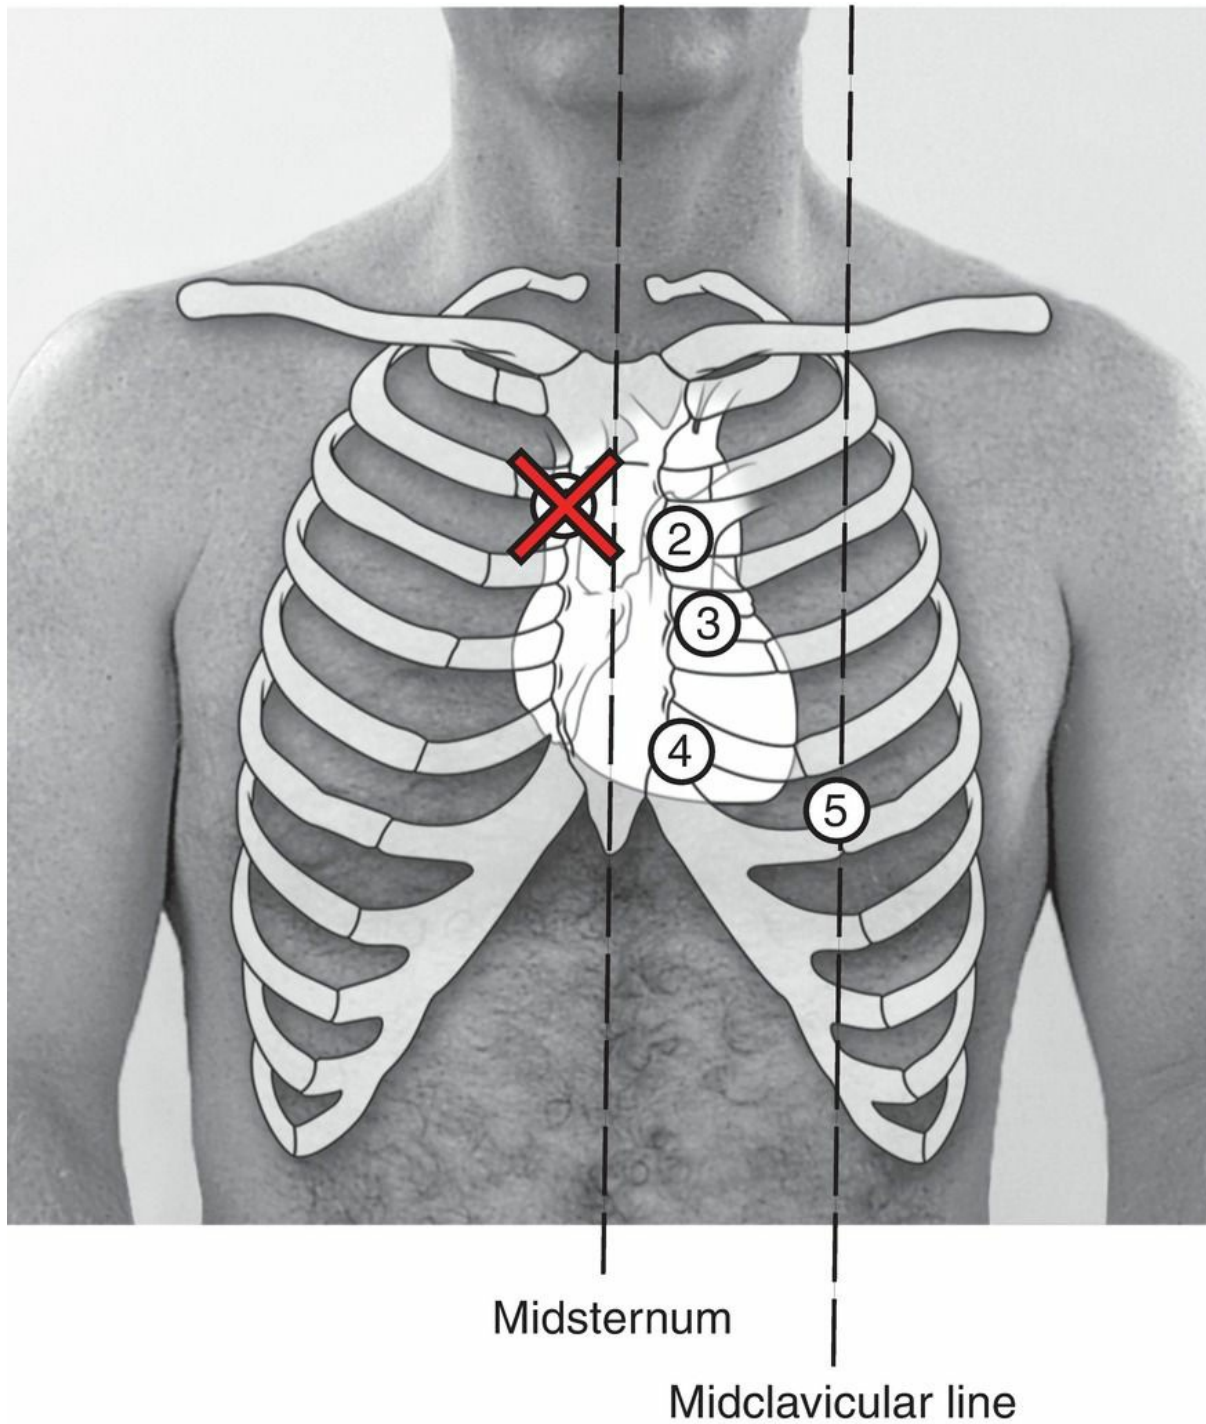

CN: Reduction of risk potential; CL: Synthesize

74. 2. The nurse should verify that the **HCP**  has requested to withhold the metformin prior to any procedure requiring dye such as a cardiac catheterization due to the increased risk of lactic acidosis. Additionally, the drug will usually be withheld for up to 48 hours following a procedure involving dye while it clears the client's system. The HCP may prescribe sliding scale insulin during this time if needed. Regardless of how or when the medication is administered, the medication should be withheld. The amount of protein in the client's diet prior to the cardiac catheterization has no correlation with the medication or the test.

CN: Pharmacological and parenteral therapies; CL: Synthesize

75. To assess a murmur from aortic stenosis, the stethoscope is placed at the second intercostal space right of sternum; (1) location, (2) the pulmonic valve area, (3) Erb's point, (4) tricuspid valve area, and (5) mitral valve area.

 CN: Physiological adaptation; CL: Apply

76. 2,3,4. For clients scheduled for a cardiac catheterization, it is important to assess for iodine sensitivity, verify written **consent** , and instruct the client to take nothing by mouth for 6 to 18 hours before the procedure. Oral medications are withheld unless specifically prescribed. A urinary drainage

catheter is rarely required for this procedure.

CN: Reduction of risk potential; CL: Apply

77. 3. Assessment of circulatory status, including observation of the puncture site, is of primary importance after a cardiac catheterization. Laboratory values and skin warmth and turgor are important to monitor but are not the most important initial nursing assessment. Neurologic assessment every 15 minutes is not required.

CN: Reduction of risk potential; CL: Analyze

78. 2. Common adverse effects of lidocaine hydrochloride include dizziness, tinnitus, blurred vision, tremors, numbness and tingling of extremities, excessive perspiration, hypotension, seizures, and finally coma. Cardiac effects include slowed conduction and cardiac arrest. Palpitations, urinary frequency, and lethargy are not considered typical adverse reactions to lidocaine.

CN: Pharmacological and parenteral therapies; CL: Analyze

79. 2. The nurse should immediately assess the blood pressure since nitroprusside and furosemide can cause severe hypotension from a decrease in preload and afterload. If the client is hypotensive, the nitroprusside dose should be reduced or discontinued. Urine output should then be monitored to make sure there is adequate renal perfusion. A 12-lead EKG is performed if the client experiences chest pain. A reduction in pulmonary artery pressures should improve the pulmonary congestion and lung sounds.

CN: Physiological adaptation; CL: Synthesize

80. 1. Preoperatively, anticoagulants may be prescribed for the client with advanced valvular heart disease to prevent emboli. Postoperatively, all clients with mechanical valves and some clients with bioprosthesis are maintained indefinitely on anticoagulant therapy. Adhering strictly to a dosage schedule and observing specific precautions are necessary to prevent hemorrhage or thromboembolism. Some clients are maintained on lifelong antibiotic prophylaxis to prevent recurrence of rheumatic fever. Episodic prophylaxis is required to prevent infective endocarditis after dental procedures or upper respiratory, gastrointestinal, or genitourinary tract surgery. Diet modification,

activity restrictions, and dental care are important; however, they do not have as much significance postoperatively as medication therapy does.

CN: Reduction of risk potential; CL: Evaluate

81. 4. Management of postoperative pain is a priority for the client after surgery, including valve replacement surgery. The client and family should be informed that pain will be assessed by the nurse and medications will be given to relieve the pain. The client will stay in the ICU as long as monitoring and intensive care are needed. Sensory deprivation and overload, high noise levels, and disrupted sleep and rest patterns are some environmental factors that affect recovery from valve replacement surgery.

CN: Reduction of risk potential; CL: Synthesize

82. 2,3,4. The hemoglobin and hematocrit should be assessed to evaluate blood loss. An elevated INR and PTT and decreased platelet count increase the risk for bleeding. The client may require blood products depending on lab values and severity of bleeding; therefore, availability of blood products should be confirmed by calling the blood bank. Close monitoring of blood loss from the mediastinal chest tubes should be done. Warfarin is an anticoagulant that will increase bleeding. Anticoagulation should be held at this time. Information is needed on the type of valve replacement. For a mechanical heart valve, the INR is kept at 2 to 3.5. Tissue valves do not require anticoagulation. Dopamine should NOT be initiated if the client is hypotensive from hypovolemia. Fluid volume assessment should always be done first. Volume replacement should be initiated in a hypovolemic client prior to starting an inotrope such as dopamine.

CN: Physiological adaptation; CL: Synthesize

83. 1. Many factors help prevent wound infections, including washing hands carefully, using sterile prepackaged supplies and equipment, cleaning the incisional area well, and disposing of soiled dressings properly. However, most authorities say that the single most effective measure in preventing wound infections is to wash the hands carefully before and after changing dressings. Careful handwashing is also important in reducing other infections often acquired in hospitals, such as urinary tract and respiratory tract infections.

CN: Reduction of risk potential; CL: Synthesize

84. 1. In an immobilized client, calcium leaves the bone and concentrates in the extracellular fluid. When a large amount of calcium passes through the kidneys, calcium can precipitate and form calculi. Nursing interventions that help prevent calculi include ensuring a liberal fluid intake (unless contraindicated). A diet rich in acid should be provided to keep the urine acidic, which increases the solubility of calcium. Preventing constipation is not associated with excessive calcium excretion. Limiting foods rich in calcium, such as dairy products, will help in preventing renal calculi.

CN: Physiological adaptation; CL: Synthesize

85. 3. INR is the value used to assess effectiveness of the warfarin sodium therapy. INR is the prothrombin time ratio that would be obtained if the thromboplastin reagent from the World Health Organization was used for the plasma test. It is now the recommended method to monitor effectiveness of warfarin sodium. Generally, the INR for clients administered warfarin sodium should range from 2 to 3. In the past, prothrombin time was used to assess effectiveness of warfarin sodium and was maintained at 1.5 to 2.5 times the control value. Partial thromboplastin time is used to assess the effectiveness of heparin therapy. Fresh frozen plasma or vitamin K is used to reverse warfarin sodium's anticoagulant effect, whereas protamine sulfate reverses the effects of heparin. Warfarin sodium will help to prevent blood clots.

CN: Pharmacological and parenteral therapies; CL: Apply

86. 1,4,5. Daily dental care including brushing the teeth twice a day and flossing once a day and frequent checkups by a dentist who is informed about the client's condition are required to maintain good oral health. The client can use a regular toothbrush; it is not necessary to avoid use of an electric toothbrush. Taking antibiotics prior to certain dental procedures is recommended only if the client has a prosthetic valve or a heart transplant. It is not necessary to use an antibiotic mouthwash.

CN: Reduction of risk potential; CL: Create

87. 2. Most cardiac surgical clients have median sternotomy incisions,

which take about 3 months to heal. Measures that promote healing include avoiding heavy lifting, performing muscle reconditioning exercises, and using caution when driving. Showering or bathing is allowed as long as the incision is well approximated with no open areas or drainage. Activities should be gradually resumed on discharge.

 CN: Safety and infection control; CL: Evaluate

88. 1. Verbalized concerns from this client may stem from anxiety over the changes in the body after open-heart surgery. Although the client may - experience depression related to altered health status or may have a lack of knowledge regarding the postoperative course, the client is pointing out the changes in the body image. The client is not concerned about altered tissue perfusion.

 CN: Psychosocial integrity; CL: Analyze

The Client with Hypertension

89. 1. The effect of a beta-blocker is a decrease in heart rate, contractility, and afterload, which leads to a decrease in blood pressure. The client at first may have an increase in fatigue when starting the beta-blocker. The mechanism of action does not improve blood sugar or urine output.

 CN: Pharmacological and parenteral therapies; CL: Evaluate

90. 2. There was a significant change in both blood pressure and heart rate with position change. This indicates inadequate blood volume to sustain normal values. Normal postural changes allow for an increase in heart rate of 5 to 20 bpm, a possible slight decrease of <5 mm Hg in the systolic blood pressure, and a possible slight increase of <5 mm Hg in the diastolic blood pressure.

 CN: Management of care; CL: Analyze

91. 1,3,5. Clonidine is a central-acting adrenergic antagonist. It reduces sympathetic outflow from the central nervous system. Dry mouth, impotence, and sleep disturbances are possible adverse effects. Hyperkalemia and pancreatitis are not anticipated with use of this drug.

 CN: Pharmacological and parenteral therapies; CL: Apply

92. 200 mcg First, calculate the number of milligrams per milliliter:

$$\frac{50 \text{ mg}}{250 \text{ mL}} = \frac{1 \text{ mg}}{5 \text{ mL}} = \frac{0.2 \text{ mg}}{1 \text{ mL}}$$

Next, calculate the number of micrograms in each milligram:

$$0.2 \text{ mg} \times \frac{1,000 \text{ mcg}}{1 \text{ mg}} = 200 \text{ mcg}$$

 CN: Pharmacological and parenteral therapies; CL: Apply

93. 1. Furosemide is a diuretic often prescribed for clients with hypertension or heart failure; the drug should not affect a client's ability to drive safely. Furosemide may cause orthostatic hypotension, and clients should be instructed to be careful when changing from supine to sitting to standing position. Diuretics should be taken in the morning if possible to prevent sleep disturbance due to the need to get up to void. Furosemide is a loop diuretic that is not potassium sparing; clients should take potassium supplements as prescribed and have their serum potassium levels checked at prescribed intervals.

 CN: Pharmacological and parenteral therapies; CL: Evaluate

94. 2,3. Changing positions slowly and avoiding long periods of standing may limit the occurrence of orthostatic hypotension. Scheduling regular medication times is important for blood pressure management, but this aspect is not related to the development of orthostatic hypotension. Excessive alcohol intake and hot baths are associated with vasodilation.

 CN: Reduction of risk potential; CL: Create

95. 1. Atenolol is a beta-adrenergic antagonist indicated for management of hypertension. Sudden discontinuation of this drug is dangerous because it may exacerbate symptoms. The medication should not be discontinued without a prescription. Blood pressure needs to be monitored more frequently

than annually in a client who is newly diagnosed and treated for hypertension. Clients are not usually placed on a 2-g sodium diet for hypertension.

CN: Pharmacological and parenteral therapies; CL: Synthesize

96. 3. Processed and cured meat products, such as cold cuts, ham, and hot dogs, are all high in both fat and sodium and should be avoided on a low-calorie, low-fat, low-salt diet. Dietary restrictions of all types are complex and difficult to implement with clients who are basically asymptomatic.

CN: Basic care and comfort; CL: Apply

97. 1,2,4,6. Metoprolol is a beta-adrenergic blocker indicated for hypertension, angina, and myocardial infarction. The tablets should be taken with food at same time each day; they should not be chewed or crushed. The **HCP**  should be notified if pulse falls below 50 for several days. Blood glucose should be checked regularly during therapy since increased episodes of hypoglycemia may occur. It may mask evidence of hypoglycemia such as palpitations, tachycardia, and tremor. Use of any OTC decongestants, asthma and cold remedies, and herbal preparations must be avoided. Fainting spells may occur due to exercise or stress, and the dosage of the drug may need to be reduced or discontinued.

CN: Pharmacological and parenteral therapies; CL: Create

98. 1,2,3,5. Chlorothiazide causes increased urination and decreased swelling (if there is edema) and weight loss. It is important to check and record weight two to three times per week at same time of day with similar amount of clothing. Clients should not drink alcoholic beverages or take other medications without the approval of the **healthcare provider (HCP)** . Reducing sodium intake in the diet helps diuretic drugs to be more effective and allows smaller doses to be taken. Smaller doses are less likely to cause adverse effects, and therefore, excessive table salt as well as salty foods should be avoided. Chlorothiazide is a diuretic that is prescribed for lower blood pressure and may cause dizziness and faintness when the client stands up suddenly. This can be prevented or decreased by changing positions slowly. If dizziness is severe, the HCP must be notified. Diuretics may cause sensitivity to sunlight; hence the need to avoid prolonged exposure to

sunlight, use sunscreens, and wear protective clothing. Chlorothiazide causes increased urination and must be taken early in the day to decrease nighttime trips to the bathroom. Fewer bathroom trips mean less interference with sleep and less risk of falls. The client should not change the dosage without consulting the HCP.

CN: Pharmacological and parenteral therapies; CL: Evaluate

99. 4. Tailoring or individualizing a program to the client's lifestyle has been shown to be an effective strategy for changing health behaviors. Providing a written program, explaining the program to the client's spouse, and reassuring the client that he or she can do the program may be helpful but are not as likely to promote adherence as individualizing the program.

CN: Psychosocial integrity; CL: Synthesize

100. 3. A plan to reduce or stop smoking begins with establishing the client's personal daily smoking pattern and activities associated with smoking. It is important that the client understands the associated health and environmental risks, but this knowledge has not been shown to help clients change their smoking behavior.

CN: Psychosocial integrity; CL: Synthesize

101. 1. Propranolol is a beta-adrenergic blocking agent. Actions of propranolol include reducing heart rate, decreasing myocardial contractility, and slowing conduction. Propranolol does not increase norepinephrine secretion, cause vasodilation, or block conversion of angiotensin I to angiotensin II.

CN: Pharmacological and parenteral therapies; CL: Apply

102. 3. In most instances, clients with hypertension require lifelong treatment and their hypertension cannot be managed successfully without changes in health behavior. The client must first commit to making these long-term changes. The changes will involve taking medications, stopping smoking, and losing weight, but the client must first accept the need for a lifelong management and establish a vision and plan to control the hypertension.

CN: Psychosocial integrity; CL: Synthesize

The Client with Atrial Fibrillation and Other Dysrhythmias

103. 2,1,3,4. To decrease myocardial workload and promote timely intervention, the client should be assisted to the bed. Assessing vital signs provides the data needed to determine client tolerance. Early initiation of an intravenous access will enable timely medication administration if it is emergently needed. While a 12-lead electrocardiogram is needed, it can be obtained after the IV is initiated.

 CN: Physiological adaptation; CL: Synthesize

104. 2,4,5. This ECG strip indicates the client has atrial fibrillation. There is no P wave and PR interval; these are replaced with a fine wavy lines. In atrial fibrillation, the ventricular rate may be normal, slow, or fast. Clients with atrial fibrillation may have palpitations secondary to a fast and irregular atrial rhythm. Because atrial fibrillation also may result in a sudden decrease in cardiac output, the client may also experience light-headedness and shortness of breath. A carotid bruit, nausea, and a systolic murmur are not manifestations of new-onset atrial fibrillation.

 CN: Physiological adaptation; CL: Analyze

105. 4. The purpose of EPS is to study the heart's electrical system. During this invasive procedure, a special wire is introduced into the heart to produce dysrhythmia. To prepare for this procedure, the client should be NPO for 6 to 8 hours before the test, and all antidysrhythmics are held for at least 24 hours before the test in order to study the dysrhythmia without the influence of medications. Because the client's verbal responses to the rhythm changes are extremely important, sedation is avoided if possible.

 CN: Physiological integrity; CL: Create

106. 2. Characteristics of atrial fibrillation include pulse rate >100 bpm, totally irregular rhythm, and no definite P waves on the ECG. During assessment, the nurse is likely to note the irregular rate and should report it to the **healthcare provider (HCP)** . A weak, thready pulse is characteristic of a client in shock. Two regular beats followed by an irregular beat may indicate a premature ventricular contraction.

 CN: Reduction of risk potential; CL: Analyze

107. 1,5. The nurse must teach the client how to take and record the pulse daily. The client should be instructed to avoid lifting the operative-side arm above shoulder level for 1 week postinsertion. It takes up to 2 months for the incision site to heal and full range of motion to return. The client should avoid heavy lifting until approved by the **healthcare provider (HCP)** 📖. The pacemaker metal casing does not set off airport security alarms, so there are no travel restrictions. Prolonged immobilization is not required. Microwave ovens are safe to use and do not alter pacemaker function.

🔑 CN: Reduction of risk potential; CL: Create

108. 1. Transcutaneous pacemaker therapy provides an adequate heart rate to a client in an emergency situation. Defibrillation and a lidocaine infusion are not indicated for the treatment of third-degree heart block. Transcutaneous pacing is used temporarily until a transvenous or permanent pacemaker can be inserted.

🔑 CN: Physiological adaptation; CL: Synthesize

109. 1,3,4,2. Because atrial fibrillation causes a decrease in cardiac output, the heart rate increases in response to this drop. As a result of an increased heart rate, the oxygen demands of the heart increase. It is important for oxygen to be administered first to help compensate for the increased oxygen demand and cardiac workload. Placing the client on a cardiac monitor will help confirm a diagnosis of atrial fibrillation. Performing vital signs will determine the client's response to the abnormal rhythm and responses to treatment. If the rhythm is determined to be atrial fibrillation, it will be necessary for an IV to be inserted so medication can be administered.

🔑 CN: Physiological integrity; CL: Synthesize

110. 3. The spouse can have physical contact with the client, but if the ICD were to discharge while the spouse had contact with the client, the spouse would feel a "tingle" but would not be harmed. There is not a warning device on the ICD.

🔑 CN: Management of care; CL: Synthesize

111. 2. Maintaining cardiac conduction stability to prevent arrhythmias is a priority immediately after artificial pacemaker implantation. The client

should have continuous electrocardiographic monitoring until proper pacemaker functioning is verified. Skin integrity, while important, is not an immediate concern. The pacemaker is used to increase heart rate and cardiac output, not decrease it. The client should limit activity for the first 24 to 48 hours after pacemaker insertion. The client should also restrict movement of the affected extremity for 24 hours.

 CN: Reduction of risk potential; CL: Synthesize

112. 3. Education is a major component of the discharge plan for a client with an artificial pacemaker. The client with a permanent pacemaker needs to be able to state specific information about safety precautions, such as to refrain from lifting more than 3 lb (1.35 kg) or stretching and bending. The client should know how to count the pulse and do so daily or as instructed by the **healthcare provider (HCP)** . The client will not necessarily be placed on a low-cholesterol diet. The client should resume activities and does not need to remain on bed rest. The client should know signs and symptoms of an MI but is not at risk because of the pacemaker.

 CN: Basic care and comfort; CL: Evaluate

113. 1,3,4. The client has atrial fibrillation and will have an irregularly irregular pulse and will commonly be tachycardic, with rapid ventricular responses (heart rates) typically in the 110 to 140 range, but rarely over 150 to 170. The goal of treatment is the restoration of sinus rhythm. With a heart rate >150 and symptoms such as shortness of breath, dizziness and syncope, and chest pain, synchronized cardioversion will most likely be the treatment of choice. With more controlled heart rates and more minor signs and symptoms, chemical conversion with drugs such as diltiazem and digoxin prior to other interventions such as synchronized cardioversion with appropriate anticoagulation may be attempted. Because of the decreased cardiac output, monitoring is essential. Obtaining consent for cardioversion requires a prescription from a **healthcare provider (HCP)** , but with the current heart rate, having cardioversion is a very strong possibility for this client. Defibrillation is used for ventricular fibrillation, not atrial fibrillation. Teaching the client about warfarin will be a possibility, but not an immediate intervention. Clients in continued atrial fibrillation usually require some form of anticoagulation. Drawing labs for CBCs to detect anemia or infection, and

thyroid function studies (to determine thyrotoxicosis, a rare, but not-to-be-missed cause, especially in older adults), serum electrolytes, and BUN/creatinine (looking for electrolyte disturbances or renal failure) are commonly drawn for determining the cause of the atrial fibrillation; they are not an immediate action.

CN: Physiological adaptation; CL: Synthesize

The Client Requiring Rapid Response or Cardiopulmonary Resuscitation

114. 3. Transcutaneous pads should be placed on the client with third-degree heart block. For a client who is symptomatic, transcutaneous pacing is the treatment of choice. The hemodynamic stability and pulse should be assessed prior to calling a code or initiating CPR. Defibrillation is performed for ventricular fibrillation or ventricular tachycardia with no pulse.

CN: Management of care; CL: Synthesize

115. 3. This ECG strip indicates the client has ventricular tachycardia. The nurse should first check the client for the presence of a pulse. The presence of a pulse determines the treatment for ventricular tachycardia. It is also important to assess the client's heart rate and level of consciousness. Cardioversion may be used to treat hemodynamically unstable tachycardias. Assessment of instability is required before cardioversion. It is not appropriate to begin CPR unless the pulse is absent. Defibrillation is used to treat ventricular fibrillation or pulseless ventricular tachycardia.

CN: Physiological adaptation; CL: Synthesize

116. 2. Pupillary reaction is the best indication of whether oxygenated blood has been reaching the client's brain. Pupils that remain widely dilated and do not react to light may indicate lack of oxygenation and that serious brain damage may have occurred. The pulse rate may be normal, mucous membranes may still be pink, and systolic blood pressure may be 80 mm Hg or higher, yet there can be inadequate oxygenation to the brain.

CN: Reduction of risk potential; CL: Evaluate

117. 3. Amiodarone is used for the treatment of premature ventricular

contractions, ventricular tachycardia with a pulse, atrial fibrillation, and atrial flutter. Amiodarone is not used as initial therapy for a pulseless dysrhythmia.

CN: Pharmacological and parenteral therapies; CL: Evaluate

118. 2. Because of its location near the xiphoid process, the liver is the organ most easily damaged from pressure exerted over the xiphoid process during CPR. The pressure on the victim's chest wall should be sufficient to compress the heart but not so great as to damage internal organs. Injury may result, however, even when CPR is performed properly.

CN: Reduction of risk potential; CL: Apply

119. 4. An adult's sternum must be depressed 2 inches (5 cm) with each compression to ensure adequate heart compression.

CN: Reduction of risk potential; CL: Apply

120. 4. If the chest wall is not rising with rescue breaths, the head should be repositioned first to ensure that the airway is adequately opened. A bag mask device allows for delivery of 100% oxygen but is difficult to manage if there is just one rescuer; ideally, two persons are used to operate the bag mask device, one to maintain the seal and the other to provide the ventilations. Compressions should be maintained at 100 per minute.

CN: Physiological adaptation; CL: Synthesize

121. 1. The exhalation phase of ventilation is a passive activity that occurs during CPR as part of the normal relaxation of the victim's chest. No action by the rescuer is necessary.

CN: Reduction of risk potential; CL: Apply

122. 2. After a person is without cardiopulmonary function for 4 to 6 minutes, permanent brain damage is almost certain. To prevent permanent brain damage, it is important to begin CPR promptly after a cardiopulmonary arrest.

CN: Reduction of risk potential; CL: Apply

123. 2. The Heimlich maneuver should be administered only to a victim who cannot make *any* sounds due to airway obstruction. If the victim can

whisper words or cough, some air exchange is occurring and the emergency medical system should be called instead of attempting the Heimlich maneuver. Cyanosis may accompany or follow choking; however, the Heimlich maneuver should only be initiated when the victim cannot speak.

 CN: Reduction of risk potential; CL: Apply

124. 4. The thrusts should be delivered below the xiphoid process, but above the umbilicus, to minimize the risk of internal injuries.

 CN: Reduction of risk potential; CL: Apply

125. 2. The priority action is to assess the client and determine whether the rhythm is life threatening. More information, including vital signs, should be obtained, and the nurse should notify the **HCP** . A bolus of lidocaine may be prescribed to treat this arrhythmia. This is not a code-type situation unless the client has been determined to be in a life-threatening situation.

 CN: Physiological adaptation; CL: Synthesize

126. 1,2,4,5. Vital signs give an important initial assessment of this client's status. The client may experience burns from the patches and current used for the cardioversion. Therefore, it is important to assess the skin of the chest wall for redness or burns. Because conscious sedation is used for this procedure, assessing the client's level of consciousness also is an important initial step. Attaching the client to cardiac monitoring is also important to assess rhythm abnormalities. There is no arterial puncture associated with the procedure.

 CN: Reduction of risk potential; CL: Synthesize

127. 4. The paddles are in the correct position. The nurse can push the shock button to defibrillate the client.

 CN: Physiological adaptation; CL: Apply

128. 2. The **rapid response team**  should be called immediately to evaluate and treat the client. There is no indication at this time for manual ventilations or chest compressions. If the family is not interfering in client care, it can be reassuring to the family to see that all possible care is being provided.

 CN: Management of care; CL: Synthesize

Managing Care, Quality, and Safety for Clients with Cardiac Health Problems

129. 2,4,3,1. Even though the chest pain experienced by Client 2 is resolved, it was recent and requires reassessment. Client 4 is scheduled to leave for major surgery very soon. The nurse should check this client and the client's chart and make certain that everything is ready so as to not delay the surgery. Client 3 has scheduled medications for blood pressure control. While not experiencing any acute problems, this medication should be administered as scheduled. Client 1 is stable at this time and can be seen last.

 CN: Management of care; CL: Create

130. 4. **UAP**  are able to measure and record intake and output. The nurse is responsible for client teaching, physical assessments, and evaluating the information collected on the client.

 CN: Management of care; CL: Synthesize

131. 1,2,4,5,6. The nurse must have assessment data and verify vital signs if necessary in order to determine the action that is required. If there is a significant change in the client's condition, the charge nurse should be notified in order to help the nurse with both this client and the nurse's other assigned clients if necessary; most acute care facilities have a **rapid response team**  that can also help assess and intervene with basic standing orders if necessary. Positioning the client in semi-Fowler's is a nursing action that may assist in breathing and relieve shortness of breath. It is important for the nurse to reassure the client by staying calm and remaining with the client. The nurse must notify the **HCP**  about the change in client's condition; the nurse must have all information available and present it in a concise and accurate manner using SBAR format including a recommendation for treatment if indicated. The nurse should stay with this client and delegate checking on other assigned clients to the charge nurse or **UAP**.

 CN: Management of care; CL: Synthesize

132. 2. The client has gained 5 lb (2.3 kg) in 3 days with a steady increase

in blood pressure. The client is exhibiting signs of heart failure, and if the client is short of breath, this will be another sign. Asking how the client is feeling is too general, and a more focused question will quickly determine the client's current health status. The scales should be calibrated periodically, but a 5-lb (2.3-kg) weight gain, along with increased blood pressure, is not likely due to problems with the scale. The weight gain is likely due to fluid retention, not drinking too much fluid.

 CN: Management of care; CL: Analyze

133. 4. The goals of managing clients outside of the hospital are for the clients to maintain health and prevent readmission; thus, interventions, such as monitoring and teaching, appear to have contributed to the low readmission rate in this group of clients. Although it is important that clients do not gain weight, view educational material, and continue to take their medication, the primary indicator of effectiveness of the program is the lack of rehospitalization.

 CN: Management of care; CL: Evaluate

134. 3. Using an individualized, printed checklist ensures that all key information is reported; the checklist can then serve as a record to which nurses can refer later. Giving a verbal report leaves room for error in memory; using an audiotape or a **medical record**  requires nurses to spend unnecessary time retrieving information.

 CN: Safety and infection control; CL: Evaluate

135. 1,2,4,5. Orthostatic hypotension is a drop in blood pressure that occurs when changing position, usually to a more upright position. Orthostatic hypotension often occurs in elderly clients, and it is a common cause of falls. Nurses must assess clients for orthostatic hypotension and assist all clients with orthostatic hypotension in standing to help prevent falls. Lower limb compression devices aid in prevention of decreased orthostatic systolic blood pressure and reduce symptoms in elderly clients with progressive orthostatic hypotension. Nurses must teach clients how to gradually change their position, and they must conduct “fall risk” assessments. Sequential compression devices may be helpful to high-risk clients and should be considered when developing the care plan.

Antihypertensive medications are not necessary for clients with orthostatic hypertension and may precipitate dangerous drops in blood pressure. The clients should be encouraged to be ambulatory.

CN: Reduction of risk potential; CL: Synthesize

136. 4,5. Performing vital signs and obtaining intake and outputs are tasks that can be delegated to **UAP** . Assessing pedal pulses and administering medications and oxygen are skills that require nursing judgments.

CN: Management of care; CL: Analyze

TEST

2

The Client with Vascular Disease

- The Client with Peripheral Artery Disease
- The Client with Peripheral Vascular Disease Having an Amputation
- The Client with an Aneurysm
- The Client with Raynaud's Phenomenon
- The Client with Peripheral Venous Disease: Thrombophlebitis, Deep Vein Thrombosis, and Embolus Formation
- The Client with Varicose Veins
- The Client with Stasis Ulcers
- Managing Care, Quality, and Safety for Clients with Vascular Disease
- Answers, Rationales, and Test-Taking Strategies

The Client with Peripheral Artery Disease

1. What instructions should the nurse give a client experiencing signs and symptoms related to decreased arterial insufficiency? Select all that apply.

- ☐ **1.** Avoid smoking and exposure to the cold.
- ☐ **2.** Take acetaminophen if experiencing pain at night.
- ☐ **3.** Take aspirin or clopidogrel as prescribed.
- ☐ **4.** Use additional bed clothes at night.
- ☐ **5.** Wear tight socks to keep feet warm.

2. The nurse is caring for a client who has just had an ankle-brachial index (ABI) test. The left arm blood pressure was 160/80 mm Hg, and a palpable systolic blood pressure of the left lower extremity was 130/60 mm Hg. These findings suggest that the client has:

- ☐ **1.** mild peripheral artery disease.

- ☐ 2. moderate peripheral artery disease.
- ☐ 3. no apparent occlusion in the left lower extremity.
- ☐ 4. severe peripheral artery disease.

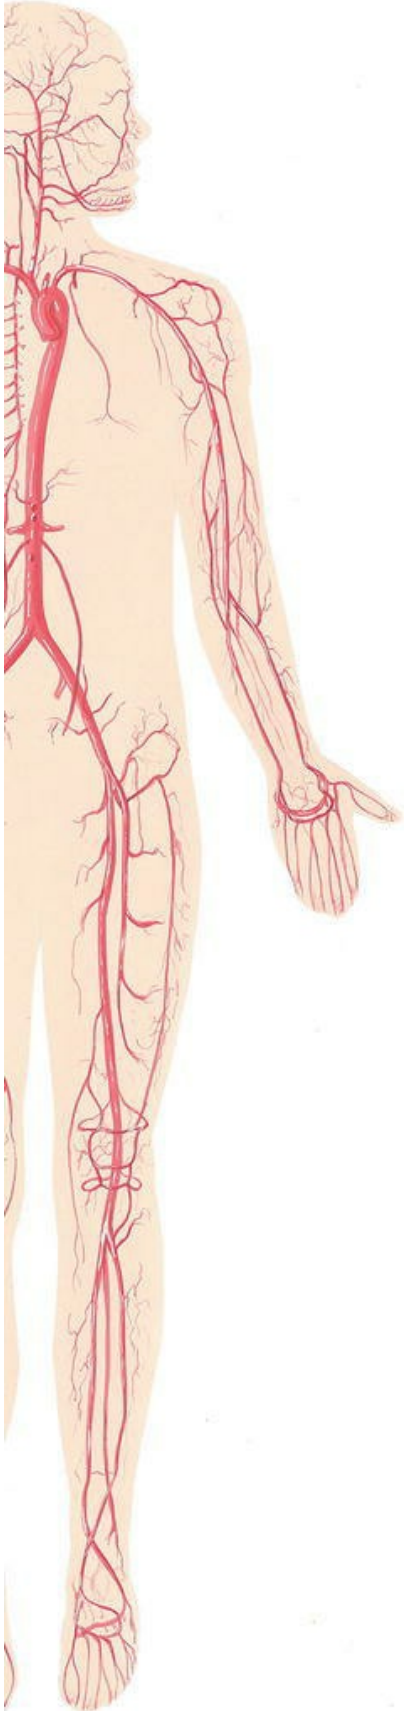

3. A client is admitted for a revascularization procedure for arteriosclerosis in the left iliac artery. To promote circulation in the extremities, the nurse should:

- ☐ 1. position the client on a firm mattress.
- ☐ 2. keep the involved extremity warm with blankets.
- ☐ 3. position the left leg at or below the body's horizontal plane.
- ☐ 4. encourage the client to raise and lower the leg four times every hour.

4. A sedentary, obese, middle-aged client is recovering from surgery to remove an embolus in the right iliac artery. The nurse should develop a discharge plan with the client that will focus on participating in which activities? Select all that apply.

- ☐ 1. aerobic activity
- ☐ 2. strength training
- ☐ 3. weight control
- ☐ 4. stress management
- ☐ 5. wearing supportive athletic shoes

5. The nurse is assessing the pulse in a client with aortoiliac disease. On the illustration below, indicate the pulse site that will give the nurse the **most** useful data.

6. The nurse is assessing a 48-year-old client with a history of smoking during a routine clinic visit. The client, who exercises regularly, reports having pain in the calf during exercise that disappears at rest. Which finding requires further evaluation?

- ☐ 1. heart rate 57 bpm
- ☐ 2. SpO₂ of 94% on room air
- ☐ 3. blood pressure 134/82 mm Hg
- ☐ 4. ankle-brachial index of 0.65

7. A client with peripheral artery disease has undergone a right femoral-popliteal bypass graft. The blood pressure has decreased from 124/80 mm Hg to 88/62 mm Hg. What should the nurse assess **first**?

- ☐ 1. IV fluid infusion rate
- ☐ 2. pedal pulses
- ☐ 3. nasal cannula flow rate
- ☐ 4. capillary refill

8. An obese client taking warfarin has dry skin due to decreased arterial blood flow. What should the nurse instruct the client to do? Select all that apply.

- ☐ 1. Apply lanolin or petroleum jelly to intact skin.
- ☐ 2. Follow a reduced-calorie, reduced-fat diet.
- ☐ 3. Inspect the involved areas daily for new ulcerations.
- ☐ 4. Limit activities of daily living (ADLs).
- ☐ 5. Use an electric razor to shave.

9. The nurse is caring for a client with peripheral artery disease who has recently been prescribed clopidogrel. The nurse understands that more teaching is necessary when the client states:

- ☐ 1. "I should not be surprised if I bruise easier or if my gums bleed a little when brushing my teeth."
- ☐ 2. "It does not really matter if I take this medicine with or without food, whatever works best for my stomach."
- ☐ 3. "I should stop taking my medicine if it makes me feel weak and dizzy."

- ☐ 4. “The doctor prescribed this medicine to make my platelets less likely to stick together and help prevent clots from forming.”

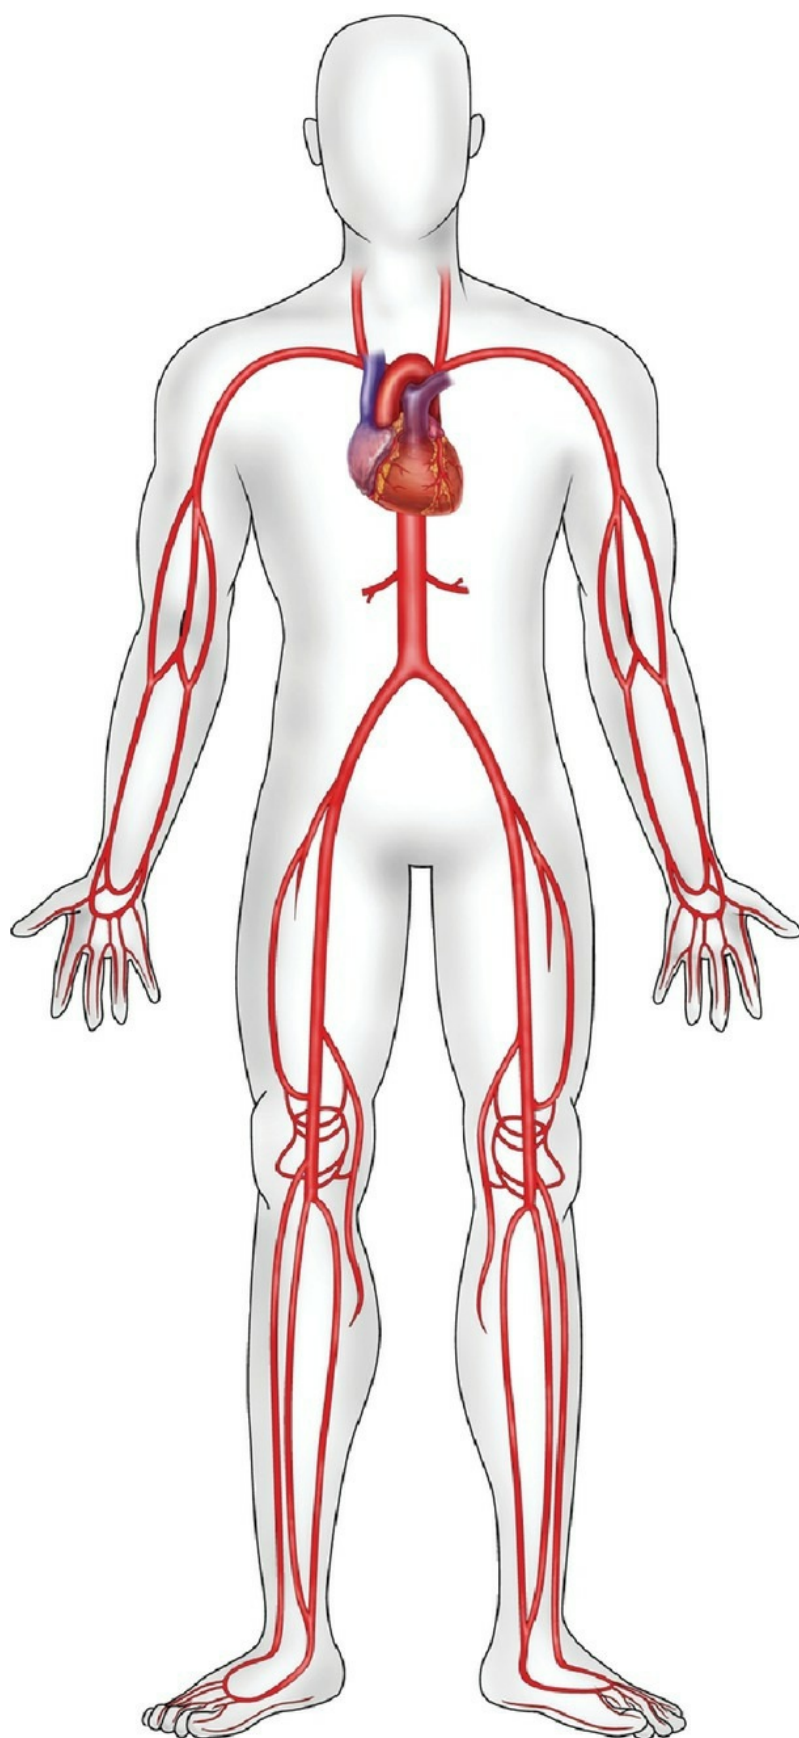

10. A client is receiving cilostazol for peripheral artery disease causing intermittent claudication. The nurse determines this medication is effective when the client reports:

- ☐ 1. “I am having fewer aches and pains.”
- ☐ 2. “I do not have headaches anymore.”
- ☐ 3. “I am able to walk further without leg pain.”
- ☐ 4. “My toes are turning grayish black in color.”

11. The client with peripheral artery disease reports both legs hurt when walking. What should the nurse instruct the client to do?

- ☐ 1. Avoid walking when the pain occurs.
- ☐ 2. Rest frequently with the legs elevated.
- ☐ 3. Wear support stockings.
- ☐ 4. Enroll in a supervised exercise training program.

12. The nurse is assessing a client with peripheral artery insufficiency. Where should the nurse palpate the client’s pulse to identify tibio-peroneal artery involvement on the right side of the body?

13. The nurse is obtaining the pulse of a client who has had a femoral-popliteal bypass surgery 6 hours ago (see below). Which assessment provides the **most** accurate information about the client's postoperative status?

☐ 1.

☐ 2.

□ 3.

☐ 4.

14. The nurse is assessing the lower extremities of the client with peripheral artery disease. Which findings are expected? Select all that apply.

- ☐ 1. hairy legs
- ☐ 2. mottled skin
- ☐ 3. pink skin
- ☐ 4. coolness
- ☐ 5. moist skin

15. The nurse is unable to palpate the client's left pedal pulses. What should the nurse do **first**?

- ☐ 1. Auscultate the pulses with a stethoscope.
- ☐ 2. Call the healthcare provider (HCP).
- ☐ 3. Use a Doppler ultrasound device.
- ☐ 4. Inspect the lower left extremity.

16. When assessing an individual with peripheral artery disease, which clinical manifestation would indicate complete arterial obstruction in the

lower left leg?

- ☐ 1. aching pain in the left calf
- ☐ 2. burning pain in the left calf
- ☐ 3. numbness and tingling in the left leg
- ☐ 4. coldness of the left foot and ankle

17. A client has returned to the surgical care unit after having femoral-popliteal bypass grafting. Indicate in which order from first to last the nurse should conduct assessment of this client. All options must be used.

1. postoperative pain

2. peripheral pulses

3. urine output

4. incision site

18. A client with heart failure has bilateral +4 edema of the right ankle that extends up to midcalf. The client is sitting in a chair in no evident distress with the legs in a dependent position. The nurse should **first**:

- ☐ 1. assist the client to the bed.
- ☐ 2. request a prescription for support stockings.
- ☐ 3. elevate the client's legs on a foot stool.
- ☐ 4. take the client's blood pressure.

19. The nurse is assessing a client who has a history of peripheral artery disease. The nurse observes that the left great toe is black. The discoloration is likely a result of:

- ☐ 1. atrophy.
- ☐ 2. contraction.
- ☐ 3. gangrene.
- ☐ 4. rubor.

20. A client has peripheral artery disease of both lower extremities. The client tells the nurse, "I have really tried to manage my condition well." Which example indicates the client is using appropriate care management strategies?

- ☐ 1. The client rests with the legs elevated above the level of the heart.
- ☐ 2. The client walks slowly but steadily for 30 minutes twice a day.
- ☐ 3. The client limits activity to walking around the house.
- ☐ 4. The client wears antiembolism stockings at all times when out of bed.

21. A client is scheduled to have an arteriogram. During the arteriogram, the client reports having nausea, tingling, and dyspnea. The nurse's **immediate** action should be to:

- ☐ 1. administer epinephrine.
- ☐ 2. inform the healthcare provider (HCP).
- ☐ 3. administer oxygen.
- ☐ 4. inform the client that the procedure is almost over.

22. A client with peripheral artery disease has chronic, severe bilateral pretibial and ankle edema; the client is on complete bed rest. To maintain skin integrity, what should the nurse do?

- ☐ 1. Administer pain medication.
- ☐ 2. Ensure fluid intake of 3,000 mL per 24 hours.
- ☐ 3. Turn the client every 1 to 2 hours.
- ☐ 4. Maintain hygiene.

23. A client who has been diagnosed with peripheral artery disease is being discharged. The client needs further instruction if the client states he or she will:

- ☐ 1. avoid heating pads.
- ☐ 2. not cross the legs.
- ☐ 3. wear leather shoes.
- ☐ 4. use iodine on an injured site.

24. A client with peripheral artery disease has femoral-popliteal bypass surgery. The **primary** goal of the plan of care after surgery is to:

- ☐ 1. maintain circulation.
- ☐ 2. prevent infection.
- ☐ 3. relieve pain.
- ☐ 4. provide education.

25. The nurse is instructing a client who is at risk for peripheral artery disease how to use knee-length elastic stockings (support hose). What instructions should the teaching plan include? Select all that apply.

- ☐ 1. Apply the elastic stockings before getting out of bed.
- ☐ 2. Remove the stockings if swelling occurs.
- ☐ 3. Remove the stockings every 8 hours, elevate the feet, and reapply in 15 minutes.
- ☐ 4. Once the stockings have been pulled over the calf, roll the remaining stocking down to make a cuff.
- ☐ 5. Keep the stockings in place for 48 hours, and reapply using a clean pair of stockings.

26. A client is scheduled to undergo right axillary-to-axillary artery bypass surgery. Immediately following surgery, to prevent infection, the nurse should:

- ☐ 1. assess the temperature in the right arm.
- ☐ 2. monitor the radial pulse in the right arm.
- ☐ 3. protect the extremity from cold.
- ☐ 4. avoid using the arm for a venipuncture.

27. One goal in caring for a client with arterial occlusive disease is to promote vasodilation in the affected extremity. To achieve this goal, the nurse should encourage the client to:

- ☐ 1. avoid eating low-fat foods.

- ☐ 2. elevate the legs above the heart.
- ☐ 3. stop smoking.
- ☐ 4. begin a jogging program.

28. The nurse is caring for a client with peripheral artery disease who has just returned from having a percutaneous transluminal balloon angioplasty. Which of these findings require **immediate** attention from the nurse?

- ☐ 1. a change in the intensity of the pulse from the baseline
- ☐ 2. pain “2 out of 10” at the catheterization site
- ☐ 3. shiny skin and a hairless appearance on the affected leg
- ☐ 4. the presence of an ulcer on the limb of the catheterization site

29. Which instructions should be included in the plan of care for a client who had a left femoral-popliteal bypass yesterday? Select all that apply.

- ☐ 1. Turn frequently, and use pillows to support the incision.
- ☐ 2. Encourage the client to change positions frequently to prevent atelectasis.
- ☐ 3. Place the left leg in a knee-flexed position to promote oxygenation.
- ☐ 4. Place the client in supine position, and elevate the leg above the heart to prevent edema.
- ☐ 5. Encourage the client to walk short distances to promote circulation.
- ☐ 6. Encourage the client to maintain bed rest to prevent stress on suture line.

30. The client with peripheral artery disease has been prescribed diltiazem. The nurse should determine the effectiveness of this medication by assessing the client for:

- ☐ 1. relief of anxiety.
- ☐ 2. sedation.
- ☐ 3. vasoconstriction.
- ☐ 4. vasodilation.

31. A client is receiving pentoxifylline for intermittent claudication. The nurse should determine the effectiveness of the drug by asking if the client:

- ☐ 1. has less pain in the legs.
- ☐ 2. can wiggle the toes.

- ☐ 3. is urinating more frequently.
- ☐ 4. is less dizzy.

32. A client with peripheral artery disease, coronary artery disease, and chronic obstructive pulmonary disease takes theophylline 200 mg twice daily every day and digoxin 0.5 mg once a day. The healthcare provider (HCP) now prescribes pentoxifylline. To prevent adverse effects, the nurse should monitor the client's:

- ☐ 1. digoxin level.
- ☐ 2. partial thromboplastin time (PTT).
- ☐ 3. serum cholesterol level.
- ☐ 4. theophylline level.

33. A client with a history of coronary artery disease (CAD) has been diagnosed with peripheral artery disease. The healthcare provider (HCP) started the client on pentoxifylline once daily. Approximately 1 hour after receiving the initial dose of pentoxifylline, the client reports having chest pain. The nurse should **first**:

- ☐ 1. initiate the rapid response team.
- ☐ 2. contact the healthcare provider.
- ☐ 3. have the client rest in bed.
- ☐ 4. start an intravenous infusion of normal saline.

34. A client with peripheral artery disease is recovering from surgery to insert an aortofemoral-popliteal bypass graft. When developing a postoperative education plan, which question by the nurse will provide the **most** helpful information?

- ☐ 1. "How did you manage your health before admission?"
- ☐ 2. "How far could you walk without pain before surgery?"
- ☐ 3. "What is your home environment like?"
- ☐ 4. "Do you have problems with urine retention?"

35. The client with peripheral artery disease and a history of hypertension is to be discharged on a low-fat, low-cholesterol, low-sodium diet. Which should be the nurse's **first** step in planning the dietary instructions?

- ☐ 1. Determine the client's knowledge level about cholesterol.

- ☐ 2. Ask the client to name foods high in fat, cholesterol, and salt.
- ☐ 3. Explain the importance of complying with the diet.
- ☐ 4. Assess the family's food preferences.

The Client with Peripheral Vascular Disease Having an Amputation

36. While the nurse is providing preoperative teaching for a client with peripheral vascular disease who is to have a below-the-knee amputation, the client says, "I hate the idea of being an invalid after they cut off my leg." The nurse's **most** therapeutic response should be:

- ☐ 1. "Focusing on using your one good leg will make your recovery easier."
- ☐ 2. "Tell me more about how you are feeling."
- ☐ 3. "We will talk more about this after your surgery."
- ☐ 4. "You are fortunate to have a wife who can take care of you."

37. The client asks the nurse, "Why can't the doctor tell me exactly how much of my leg they're going to take off? Don't you think I should know that?" The nurse responds, knowing that the final decision on the level of the amputation will depend primarily on:

- ☐ 1. the need to remove as much of the leg as possible.
- ☐ 2. the adequacy of the blood supply to the tissues.
- ☐ 3. the ease with which a prosthesis can be fitted.
- ☐ 4. considering how to fit a prosthesis.

38. A client has undergone an amputation of three toes and a femoral-popliteal bypass. The nurse should teach the client that after surgery, which leg position is contraindicated while sitting in a chair?

- ☐ 1. crossing the legs
- ☐ 2. elevating the legs
- ☐ 3. flexing the ankles
- ☐ 4. extending the knees

39. The nurse is monitoring a client after an above-the-knee amputation and notes that blood has saturated through the distal part of the dressing. What should the nurse do **immediately**?

- ☐ 1. Apply a tourniquet.
- ☐ 2. Assess vital signs.
- ☐ 3. Call the healthcare provider (HCP).
- ☐ 4. Elevate the involved extremity with a large pillow.

40. The client has had a below-the-knee amputation secondary to arterial occlusive disease. The nurse is instructing the client in residual limb care. Which statement by the client indicates that the client understands how to implement the plan of care?

- ☐ 1. "I should inspect the incision carefully when I change the dressing every other day."
- ☐ 2. "I should wash the incision, dry it, and apply moisturizing lotion daily."
- ☐ 3. "I should rewrap the stump as often as needed."
- ☐ 4. "I should elevate the stump on pillows to decrease swelling."

The Client with an Aneurysm

41. The nurse is developing a discharge teaching plan for a client who had a graft insertion for an abdominal aortic aneurysm 4 days ago. The nurse reviews the client's chart for information about the client's history. Key findings are noted in the chart below.

History and Physical

- 1) Smokes four cigars a month.
- 2) Vital signs: blood pressure, ranges from 150/76-170/98 mm Hg; heart rate, 90-100 bpm; respirations, 12-18 bpm; temperature, 99.9°F (37.8°C).
- 3) +1 bilateral ankle edema.

Based on the data and expected outcomes, which should the nurse emphasize in the teaching plan?

- ☐ 1. food intake
- ☐ 2. fluid volume
- ☐ 3. skin integrity
- ☐ 4. tissue perfusion

42. A client is admitted with a 6.5-cm thoracic aneurysm. The nurse records findings from the initial assessment in the client's chart, as shown below.

Vital Signs		
Date	05/07	
Time	1000	
Blood pressure	160/90 mm Hg	
Heart rate	74 bpm	
Respirations	20/min	
	G. Fuentes, RN	

At 1030, the client has sharp midchest pain after having a bowel movement. What should the nurse do **first**?

- ☐ 1. Assess the client's vital signs.
- ☐ 2. Administer pain medication as prescribed.
- ☐ 3. Assess the client's neurologic status.
- ☐ 4. Contact the healthcare provider (HCP).

43. A client with an enlarged abdominal aorta admitted to the emergency department has severe back pain, nausea, blood pressure of 90/40 mm Hg, heart rate 128 bpm, and respirations 28/minute. In which order from first to last should the nurse implement these prescriptions? All options must be used.

1. Monitor intake and output.

2. Establish an intravenous infusion.

3. Administer pain medication.

4. Insert a nasogastric tube.

44. A client had a repair of a thoracoabdominal aneurysm 2 days ago. Which findings should the nurse consider unexpected and report to the healthcare provider (HCP) **immediately**?

- ☐ 1. abdominal pain at 5 on a scale of 0 to 10 for the last 2 days
- ☐ 2. heart rate of 100 bpm after ambulating 200 feet (0.06 km)
- ☐ 3. urine output of 2,000 mL in 24 hours
- ☐ 4. weakness and numbness in the lower extremities

45. A client is admitted to the emergency department with severe abdominal pain. A radiograph reveals a large abdominal aortic aneurysm. The **primary** goal at this time is to:

- ☐ 1. maintain circulation.
- ☐ 2. manage pain.
- ☐ 3. prepare the client for emergency surgery.
- ☐ 4. teach postoperative breathing exercises.

46. A client has sudden, severe pain in the back and chest, accompanied by shortness of breath. The client describes the pain as a “tearing” sensation.

The healthcare provider (HCP) suspects the client is experiencing a dissecting aortic aneurysm. The emergency supply cart is brought into the room because one complication of a dissecting aneurysm is:

- ☐ 1. cardiac tamponade.
- ☐ 2. stroke.
- ☐ 3. pulmonary edema.
- ☐ 4. myocardial infarction.

47. The nurse is planning care for a client who has just returned to the medical-surgical unit following repair of an aortic aneurysm. The nurse **first** should assess the client for:

- ☐ 1. decreased urinary output.
- ☐ 2. electrolyte imbalance.
- ☐ 3. anxiety.
- ☐ 4. wound infection.

48. A client underwent surgery to repair an abdominal aortic aneurysm. The surgeon made an incision that extends from the xiphoid process to the pubis. At 1200 hours 2 days after surgery, the client has abdominal distention. The nurse checks the progress notes in the client's medical record, as shown below.

Nurses Progress Notes

Date	Time	Progress Notes
07/07	2200	The client is receiving D ₅ W, 1,000 mL every 8 h. The NG tube is attached to low suction and draining well. The client has been NPO except ice chips. The client has had 10 mg morphine for pain at 6 AM E. Levine, RN

What is **most** likely contributing to the client's abdominal distention?

- ☐ 1. nasogastric (NG) tube
- ☐ 2. ice chips
- ☐ 3. IV fluid intake
- ☐ 4. morphine

49. A client is discharged after an aortic aneurysm repair with a synthetic graft to replace part of the aorta. The nurse should instruct the client to notify the healthcare provider (HCP) before having:

- ☐ 1. blood drawn.
- ☐ 2. an IV line inserted.
- ☐ 3. major dental work.
- ☐ 4. an x-ray examination.

50. The nurse is assessing a client who had an abdominal aortic aneurysm repair 2 hours ago. Which finding warrants further evaluation?

- ☐ 1. absent bowel sounds and mild abdominal distension
- ☐ 2. a BUN of 26 mg/dL (26 mmol/L) and creatinine of 1.2 mg/dL (1.2

μmol/L)

- ☐ 3. an arterial blood pressure of 80/50 mm Hg
- ☐ 4. +1 pedal pulses in bilateral lower extremities

51. The nurse is planning care for a client who had an abdominal aortic aneurysm repair 3 days ago. The nurse is reviewing the progress notes below.

Nurses Progress Notes

Date	Time	Progress Notes
2/20	0900	Temperature is 36.8°C; Pulse is 138; BP is 86/44 mm Hg; CVP is 2 mm Hg Robin Brown, RN
2/20	1100	Urine output is 20 ml/hr for the last 2 hours; Hgb is 7.8 gm/dL, IV of D5½ normal saline is infusing at 7+ cc/hr Robin Brown, RN

Two units of PRBCs have been prescribed for transfusion. What should the nurse do **first**?

- ☐ 1. Administer furosemide.
- ☐ 2. Increase the drip rate of IV fluids.
- ☐ 3. Initiate a dopamine drip.
- ☐ 4. Transfuse PRBCs.

The Client with Raynaud's Phenomenon

52. When instructing a client who has been newly diagnosed with Raynaud's phenomenon about management of care, the nurse should discuss

which topic?

- ☐ 1. scheduling a sympathectomy procedure for the next visit
- ☐ 2. using a beta-blocker medication
- ☐ 3. follow-up monitoring for development of connective tissue disease
- ☐ 4. benefit of an angioplasty to the affected extremities

53. A client has been diagnosed with Raynaud's phenomenon on the tip of the nose and fingertips. The healthcare provider (HCP) has prescribed reserpine to determine if the client will obtain relief. The client often works outside in cold weather and also smokes two packs of cigarettes per day. Which directions should be included in the discharge plan for this client? Select all that apply.

- ☐ 1. Stop smoking.
- ☐ 2. Wear a face covering and gloves in the winter.
- ☐ 3. Place fingertips in cool water to rewarm them.
- ☐ 4. Find employment that can be done in a warm environment.
- ☐ 5. Report signs of orthostatic hypotension.

54. A nurse assesses a 40-year-old female client with Raynaud's phenomenon involving her right hand. The nurse records the information in the progress notes, as shown below. From these findings, the nurse should develop a plan with the client to **first** manage:

Progress Notes

Date	Time	Progress Notes
06/10	1500	The client has a palpable but faint right radial pulse. Capillary refill on all five digits < 8 s. No observable swelling. The client is reporting numbness in the tips of all five digits. The skin is warm, dry, and red. G. Fuentes, RN

- ☐ 1. acute pain.
- ☐ 2. numbness.
- ☐ 3. lack of circulation.
- ☐ 4. potential for skin breakdown.

55. Which group is at **greatest** risk for Raynaud's phenomenon?

- ☐ 1. young women
- ☐ 2. old women
- ☐ 3. old men
- ☐ 4. young men

56. The client with Raynaud's phenomenon has coldness and numbness in the fingers. Which is an **early** sign of vasoconstriction?

- ☐ 1. cyanosis
- ☐ 2. gangrene
- ☐ 3. pallor
- ☐ 4. rubor

57. During an initial assessment of a client diagnosed with Raynaud's

phenomenon, the nurse notes a sudden color change from pink to white in the fingers. The nurse should **first** assess:

- ☐ 1. appearance of cyanosis.
- ☐ 2. radial pulse.
- ☐ 3. SpO₂ of the affected fingers.
- ☐ 4. blood pressure.

58. The nurse should instruct a client who has been diagnosed with Raynaud's phenomenon to:

- ☐ 1. immerse the hands in cold water during an episode.
- ☐ 2. wear light garments when the temperature gets below 50°F (10°C).
- ☐ 3. wear gloves when handling ice or frozen foods.
- ☐ 4. live in a cold climate.

59. In order to prevent recurrent vasospastic episodes with Raynaud's phenomenon, what should the nurse instruct the client to do?

- ☐ 1. Keep the hands and feet elevated as much as possible.
- ☐ 2. Use a vibrating massage device on the hands.
- ☐ 3. Wear gloves when obtaining food from the refrigerator.
- ☐ 4. Increase coffee intake to two cups per day.

60. A client with Raynaud's phenomenon is prescribed diltiazem. The intended outcome is:

- ☐ 1. decreased heart rate.
- ☐ 2. conversion to normal sinus rhythm.
- ☐ 3. reduced episodes of finger numbness.
- ☐ 4. increased SpO₂.

61. When giving discharge instructions to the client with Raynaud's phenomenon, the nurse should explain that the expected outcome of taking a beta-adrenergic blocking medication is to control the symptoms by:

- ☐ 1. decreasing the influence of the sympathetic nervous system on the tissues in the hands and feet.
- ☐ 2. decreasing the pain by producing analgesia.
- ☐ 3. increasing the blood supply to the affected area.

- ☐ 4. increasing monoamine oxidase.

62. A client with Raynaud's phenomenon is considering having a sympathectomy. This nurse should tell the client that the surgery is - performed:

- ☐ 1. in the early stages of the disease to prevent further circulatory disturbances.
- ☐ 2. when the disease is controlled by medication.
- ☐ 3. when the client is unable to control stress-related vasospasm.
- ☐ 4. when all other treatment alternatives have failed.

The Client with Peripheral Venous Disease: Thrombophlebitis, Deep Vein Thrombosis, and Embolus Formation

63. A client is being treated for deep vein thrombosis (DVT) in the left femoral artery. The healthcare provider (HCP) has prescribed 60 mg of enoxaparin subcutaneously. Before administering the drug, the nurse checks the client's laboratory results, noted below.

Laboratory Results

Test	Result
Prothrombin time	12.5s
INR	2.0s
Platelet count	50,000/ μ L (50×10^9 /L)

Based on these results, what should the nurse do?

- ☐ 1. Contact the pharmacist for a lower dose of the medication.
- ☐ 2. Administer the medication as prescribed.
- ☐ 3. Assess the client for signs of bruising on the extremities.

- ☐ 4. Withhold the dose of the medication and contact the healthcare provider (HCP).

64. A client with deep vein thrombosis suddenly develops dyspnea, tachypnea, and chest discomfort. What should the nurse do **first**?

- ☐ 1. Elevate the head of the bed 30 to 45 degrees.
- ☐ 2. Encourage the client to cough and deep breathe.
- ☐ 3. Auscultate the lungs to detect abnormal breath sounds.
- ☐ 4. Contact the healthcare provider (HCP).

65. A client with a recent diagnosis of deep vein thrombosis (DVT) has sudden onset of shortness of breath and chest pain that increases with a deep breath. The nurse should **first**:

- ☐ 1. assess the oxygen saturation.
- ☐ 2. call the healthcare provider (HCP).
- ☐ 3. administer morphine sulfate, 2 mg IV.
- ☐ 4. perform range-of-motion exercises in the involved leg.

66. The nurse is caring for a client with venous thrombosis of the left lower extremity. To prevent further tissue damage, it is important for the nurse to observe for which finding?

- ☐ 1. blood pressure and heart rate changes
- ☐ 2. gradual or acute loss of sensory and motor function
- ☐ 3. metabolic acidosis
- ☐ 4. swelling in the left lower extremity

67. A client with venous thrombus reports having pain in the legs. What should the nurse do **first**?

- ☐ 1. Elevate the foot of the bed.
- ☐ 2. Elevate the legs by using a pillow under the knees.
- ☐ 3. Encourage adequate fluid intake.
- ☐ 4. Massage the lower legs.

68. A 45-year-old client had a complete abdominal hysterectomy with bilateral salpingo-oophorectomy 2 days ago. The client's abdominal dressing is dry and intact. While sitting up in the chair, the client has severe pain and

numbness in her left leg. The nurse should **first**:

- ☐ 1. administer pain medication.
- ☐ 2. assess edema in the left leg.
- ☐ 3. assess color and temperature of the left leg.
- ☐ 4. encourage the client to change her position.

69. A client who is being discharged after a hospitalization for thrombophlebitis will be riding home in a car. During the 2-hour ride, what should the nurse advise the client to do?

- ☐ 1. Perform arm circles while riding in the car.
- ☐ 2. Perform ankle pumps and foot range-of-motion exercises.
- ☐ 3. Elevate the legs while riding in the car.
- ☐ 4. Take an ambulance home.

70. A client with a cerebral embolus is receiving streptokinase. The nurse should evaluate the client for which expected therapeutic outcomes of this drug therapy?

- ☐ 1. improved cerebral perfusion
- ☐ 2. decreased vascular permeability
- ☐ 3. dissolved emboli
- ☐ 4. prevention of cerebral hemorrhage

71. A client who weighs 187 lb (85 kg) has a prescription to receive enoxaparin 1 mg/kg. This drug is available in a concentration of 30 mg/0.3 mL. What dose would the nurse administer in milliliters? Record your answer to two decimal points.

_____ mL.

72. A client is on complete bed rest. The nurse should initiate measures to prevent which complication of bed rest?

- ☐ 1. air embolus
- ☐ 2. fat embolus
- ☐ 3. stress fractures
- ☐ 4. thrombophlebitis

73. Knee-high sequential compression devices have been prescribed for a

newly admitted client. The client reports new pain localized in the right calf area that is noted to be slightly reddened and warm to touch upon initial assessment. What should the nurse do **first**?

- ☐ 1. Offer analgesics as prescribed, and apply the compression devices.
- ☐ 2. Leave the compression devices off, and contact the healthcare provider (HCP) to report the assessment findings.
- ☐ 3. Massage the area of discomfort before applying the compression devices.
- ☐ 4. Leave the compression devices off, and report assessment findings to the oncoming shift.

74. A client is receiving an IV infusion of 5% dextrose in water (D₅W). The skin around the IV insertion site is red, warm to touch, and painful. The nurse should **first**:

- ☐ 1. administer acetaminophen.
- ☐ 2. change the D₅W to normal saline.
- ☐ 3. discontinue the IV.
- ☐ 4. place a warm compress on the area.

75. The nurse is planning care for a client on complete bed rest. The plan of care should include all **except**:

- ☐ 1. turning every 2 hours.
- ☐ 2. passive and active range-of-motion exercises.
- ☐ 3. use of thromboembolic disease (TED) support hose.
- ☐ 4. maintaining the client in the supine position.

76. The client is admitted with left lower leg pain, a positive Homans' sign, and a temperature of 100.4°F (38°C). The nurse should assess the client further for signs of:

- ☐ 1. aortic aneurysm.
- ☐ 2. deep vein thrombosis (DVT) in the left leg.
- ☐ 3. IV drug abuse.
- ☐ 4. intermittent claudication.

77. A client is admitted with a diagnosis of thrombophlebitis and deep

vein thrombosis of the right leg. A loading dose of heparin has been given in the emergency department, and IV heparin will be continued for the next several days. The nurse should develop a plan of care for this client that will involve:

- ☐ 1. administering aspirin as prescribed.
- ☐ 2. encouraging green leafy vegetables in the diet.
- ☐ 3. monitoring the client's prothrombin time (PT).
- ☐ 4. monitoring the client's activated partial thromboplastin time (aPTT) and international normalized ratio (INR).

78. In order to prevent deep vein thrombosis (DVT) following abdominal surgery, the nurse should:

- ☐ 1. limit fluids to 1,000 mL in 24 hours.
- ☐ 2. encourage deep breathing.
- ☐ 3. assist the client to remain sedentary.
- ☐ 4. use pneumatic compression stockings.

79. A client diagnosed with a deep vein thrombosis has heparin sodium infusing at 1,500 units/h. The concentration of heparin is 25,000 units/500 mL. If the infusion remains at the same rate for a full 12-hour shift, how many milliliters of fluid will infuse? Round your answer to a whole number.

_____ mL.

80. The nurse interviews a 22-year-old female client who is scheduled for abdominal surgery the following week. The client is obese and uses estrogen-based oral contraceptives. This client is at high risk for development of:

- ☐ 1. atherosclerosis.
- ☐ 2. diabetes.
- ☐ 3. Raynaud's disease.
- ☐ 4. thrombophlebitis.

81. A client weighs 300 lb (136 kg) and has a history of deep vein thrombosis and thrombophlebitis. When coaching a client about behaviors to maintain health, the nurse determines that the client has understood the nurse's instructions when the client states a willingness to:

- ☐ 1. limit exercise that involves walking.

- ☐ 2. lose weight by following a reduced-calorie, balanced diet.
- ☐ 3. perform leg lifts every 4 hours to strengthen hamstring muscles.
- ☐ 4. wear knee-high stockings, rolled at the top to hold the stockings up.

82. Which instructions should the nurse include when developing a teaching plan for a client being discharged from the hospital on anticoagulant therapy after having deep vein thrombosis (DVT)? Select all that apply.

- ☐ 1. Check urine for bright blood and a dark smoky color.
- ☐ 2. Walk daily as a good exercise.
- ☐ 3. Use garlic and ginger, which may decrease bleeding time.
- ☐ 4. Perform foot/leg exercises and walking around the airplane cabin when on long flights.
- ☐ 5. Prevent DVT because of risk of pulmonary emboli.
- ☐ 6. Avoid surface bumps because the skin is prone to injury.

83. A client has an emergency embolectomy for an embolus in the femoral artery. After the client returns from the recovery room, in what order, from first to last, should the nurse provide care? All options must be used.

1. Administer pain medication.

2. Draw blood for laboratory studies.

3. Regulate the IV infusion.

4. Monitor the pulses.

5. Inspect the dressing.

84. A client with deep vein thrombosis has been receiving warfarin for 2 months. The client is to go to an anticoagulant monitoring laboratory every 3 weeks. The last visit to the laboratory was 2 weeks ago. The client reports bleeding gums, increased bruising, and dark stools. What should the nurse instruct the client to do?

- ☐ 1. Decrease the dose of the warfarin.
- ☐ 2. Return to laboratory for analysis of prothrombin times.
- ☐ 3. Decrease the amount of vitamin K in the diet.
- ☐ 4. Notify the healthcare provider (HCP) about the bleeding.

The Client with Varicose Veins

85. A client is talking with the nurse about unsightly varicose veins and their discomfort. What information should the nurse provide to the client?

- ☐ 1. Avoid walking to reduce the discomfort.
- ☐ 2. Keep the legs elevated when sitting or lying down.
- ☐ 3. Sclerotherapy can be used for cosmetic improvement.
- ☐ 4. Contact a surgeon to perform a femoral-popliteal bypass graft.

86. The nurse is teaching a group of women about risk for varicose veins. Which client is at risk for varicose veins?

- ☐ 1. a client who has had a cerebrovascular accident
- ☐ 2. a client who has had anemia
- ☐ 3. a client who has had thrombophlebitis
- ☐ 4. a client who has had transient ischemic attacks

87. A client is to have sclerotherapy to treat varicose veins. The nurse should instruct the client that this procedure:

- ☐ 1. causes the veins to fade and disappear.
- ☐ 2. ensures that varicosities will not occur again.

- ☐ 3. requires a short hospitalization for complete recovery.
- ☐ 4. results in bruising lasting for 2 weeks.

88. A clinically obese client with moderately painful varicose veins chooses self-care options for managing the varicosities. The nurse should coach the client to follow which healthcare practices? Select all that apply.

- ☐ 1. Lose weight.
- ☐ 2. Wear compression stockings.
- ☐ 3. Apply lotion to the veins.
- ☐ 4. Elevate the legs.
- ☐ 5. Sleep with pillows under the knees.

The Client with Stasis Ulcers

89. A well-nourished client is admitted with a stasis ulcer. The nurse assesses the ulcer and finds excavation of the skin surface as a result of sloughing of inflammatory necrotic tissue. The healthcare provider (HCP) has prescribed the ulcer to be flushed with a fibrinolytic agent. Which goals are appropriate for this client? Select all that apply.

- ☐ 1. Increase oxygen to the tissues.
- ☐ 2. Prevent direct trauma to the ulcer.
- ☐ 3. Improve nutrition.
- ☐ 4. Prevent infection.
- ☐ 5. Reduce pain.

90. A client has had a stasis ulcer of the left ankle with 2+ pitting edema for 2 years. The client is taking chlorothiazide. The desired outcome of this drug for this client is:

- ☐ 1. improved capillary circulation.
- ☐ 2. decreased blood pressure.
- ☐ 3. wound healing.
- ☐ 4. absence of infection.

91. The nurse assesses a client with a 5×2 stasis ulcer just above the left malleolus. The wound is open with irregular, reddened, swollen edges, and there is a moderate amount of yellowish tan drainage coming from the

wound. The client verbalizes pressure-type pain and rates the discomfort at 7 on a scale of 0 to 10. To maintain tissue integrity, the **primary** nursing goal should focus on:

- ☐ 1. administering prescribed analgesics.
- ☐ 2. applying lanolin lotions to the left ankle stasis ulcer.
- ☐ 3. encouraging the client to sit up in a chair four times per day.
- ☐ 4. keeping pressure of bed linens off the area.

92. In preparation for being discharged to home, the nurse is teaching a client with a chronic right ankle stasis ulcer about wound care. The client needs further teaching when the client states: “I will:

- ☐ 1. make an appointment with a physical therapist.”
- ☐ 2. apply a home herb mixture to the wound to promote healing.”
- ☐ 3. be patient with the healing process.”
- ☐ 4. eat a balanced diet.”

Managing Care, Quality, and Safety for Clients with Vascular Disease

93. The nurse has received a change of shift report about clients. Which client should the nurse assess **first**?

- ☐ 1. a client with chronic heart failure with right upper quadrant fullness
- ☐ 2. a client in atrial fibrillation with a heart rate of 90 with a “fluttering” feeling
- ☐ 3. a client with peripheral artery disease (PAD) just returning from an angiogram
- ☐ 4. a client who had coronary artery bypass surgery 2 days ago who reports having incisional pain of “3” out of “10”

94. A client with a history of hypertension and peripheral vascular disease underwent an aortobifemoral bypass graft. Preoperative medications included pentoxifylline, metoprolol, and furosemide. On postoperative day 1, the 1200 vital signs are as follows: temperature 98.9°F (37.2°C), heart rate 132 bpm, respiratory rate 20 breaths/min, and blood pressure 126/78 mm Hg. Urine output is 50 to 70 mL/h. The hemoglobin and the hematocrit are stable. The

medications have not been prescribed for administration after surgery. Using the SBAR (Situation-Background-Assessment-Recommendation) technique for communication, the nurse contacts the healthcare provider (HCP) and recommends to:

- ☐ 1. continue the pentoxifylline.
- ☐ 2. increase the IV fluids.
- ☐ 3. restart the metoprolol.
- ☐ 4. resume the furosemide.

95. The nurse is planning care for a client who had surgery for abdominal aortic aneurysm repair 2 days ago. The pain medication and the use of relaxation and imagery techniques are not relieving the client's pain, and the client refuses to get out of bed to ambulate as prescribed. The nurse contacts the healthcare provider (HCP), explains the situation, and provides information about drug dose, frequency of administration, the client's vital signs, and the client's score on the pain scale. The nurse requests a prescription for a different, or stronger, pain medication. The HCP tells the nurse that the current prescription for pain medication is sufficient for this client and that the client will feel better in several days. The nurse should **next:**

- ☐ 1. explain to the HCP that the current pain medication and other strategies are not helping the client and it is making it difficult for the client to ambulate as prescribed.
- ☐ 2. ask the surgical resident to write a prescription for a stronger pain medication.
- ☐ 3. wait until the next shift and ask the nurse on that shift to contact the HCP.
- ☐ 4. report the incident to the team leader.

96. The nurse is making the client assignment for a group of clients. The personnel include the registered nurse (RN), a licensed practical/vocational nurse (LPN/VN), and an unlicensed assistive personnel (UAP). Which client would the nurse assign to the LPN/VN?

- ☐ 1. a client who is undergoing femoropopliteal bypass graft surgery this morning and needs the preoperative check list completed

- ☐ 2. a stable client with thrombophlebitis of the lower left extremity with limited mobility and requiring a complete bed bath
- ☐ 3. a client with a palpable abdominal mass, painful lower extremities, and a decreasing BP
- ☐ 4. a client with intermittent claudication who needs frequent assistance with getting out of bed and ambulating

97. The nurse is obtaining a blood sample for a partial thromboplastin time test prescribed for a client who is taking heparin. It is 0500 when drawing the blood. What should the nurse do? Select all that apply.

- ☐ 1. Awake the client.
- ☐ 2. Check the armband for client identification number and compare with the prescription.
- ☐ 3. Label the sample vial in front of the client.
- ☐ 4. Verify the room number with the room assignment.
- ☐ 5. Ask the client to state his/her name.

98. A client has acute arterial occlusion. The healthcare provider (HCP) has prescribed IV heparin. **Before** starting the medication, the nurse should:

- ☐ 1. review the blood coagulation laboratory values.
- ☐ 2. test the client's stools for occult blood.
- ☐ 3. count the client's apical pulse for 1 minute.
- ☐ 4. check the 24-hour urine output record.

99. The nurse is caring for a client who has a below-the-knee amputation. The client has been somewhat confused since returning from surgery last evening but has no history of falls. The client is receiving intravenous antibiotics intermittently through a peripheral IV and has prescriptions to be up with physical therapy only. Using the Morse Fall Risk Scale (see scale), what is this client's total score and risk level?

Morse Fall Risk/Scale

Item	Scale	Scoring
1. History of falling; immediate or within 3 months	No 0 Yes 25	
2. Secondary diagnosis	No 0 Yes 15	
3 Ambulatory aid Bed rest/nurse assist Crutches/cane/walker Furniture	0 15 30	
4. IV/Heparin Lock	No 0 Yes 20	
5. Gait/Transferring Normal/bedrest/ immobile Weak Impaired	0 10 20	
6. Mental status Oriented to own ability Forgets limitations	0 15	

- ☐ 1. 20, low risk
- ☐ 2. 30, medium risk

- ☐ 3. 40, medium risk
- ☐ 4. 50, high risk

Answers, Rationales, and Test-Taking Strategies

*The answers and rationales for each question follow below, along with keys () to the client need (CN) and cognitive level (CL) for each question. In addition, you will also see a glossary icon () highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 12–23 and pages 35–36 in Part 1 of this book.*

The Client with Peripheral Artery Disease

1. 1,3,4. Smoking and exposure to the cold cause vasoconstriction and should be avoided. Aspirin and clopidogrel should be taken as prescribed for the antiplatelet properties. Using extra bed clothes at night provides warmth, which increases vasodilation. The presence of pain should be investigated as it could indicate increasing arterial insufficiency. Tight socks should be avoided as they could impair circulation.

 CN: Health promotion and maintenance; CL: Synthesis

2. 1. The ABI test is a noninvasive test that compares the systolic blood pressure in the arm with that of the ankle. It may be done before or after exercise. The client's highest brachial systolic pressure is divided by the left ankle systolic blood pressure to get 0.81. This score is between 0.71 and 0.90, which suggests mild peripheral artery disease. Moderate peripheral artery disease would yield a score of 0.41 to 0.70. Severe peripheral artery disease would result in a score of 0.00 to 0.40.

 CN: Physiological adaptation; CL: Analyze

3. 3. Keeping the involved extremity at or below the body's horizontal plane will facilitate tissue perfusion and prevent tissue damage. The nurse

should avoid placing the affected extremity on a hard surface, such as a firm mattress, to avoid pressure ulcers. In addition, the involved extremity should be free from heavy overlying bed linens. The nurse should handle the involved extremity in a gentle fashion to prevent friction or pressure. Raising the leg would cause occlusion to the iliac artery, which is contrary to the goal to promote arterial circulation.

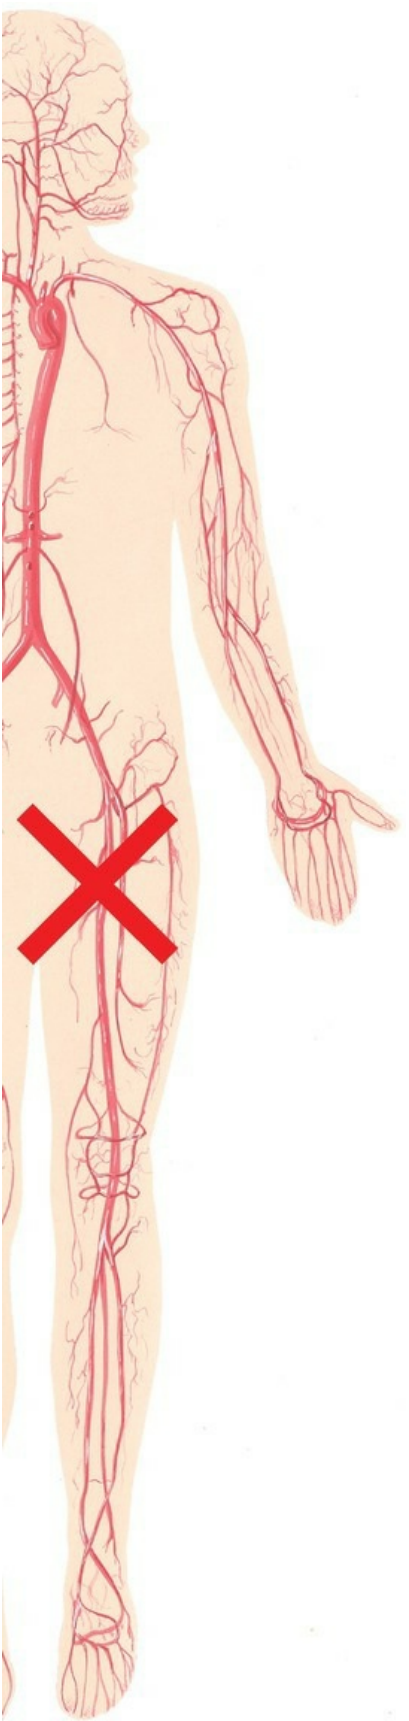

CN: Physiological adaptation; CL: Synthesize

4. 1,3. Discharge teaching begins when the client enters the hospital. One of the risk factors for clot formation is a sedentary lifestyle, and the client should engage in daily aerobic activity, such as biking or swimming (non-weight bearing). The client is also overweight and should plan to control the weight through dietary counseling or attending weight management programs in the community. Strength training is beneficial by increasing strength and lean body mass, but not helpful in preventing vascular disease. Stress management is not a focus based on the client's needs at this time. It is not necessary to wear special supportive shoes; comfortable shoes for walking are adequate.

CN: Health promotion and maintenance; CL: Create

5. The nurse should assess the femoral artery. Weak or absent femoral pulses are symptomatic of aortoiliac disease.

CN: Physiological adaptation; CL: Analyze

6. 4. An ankle-brachial index of 0.65 suggests moderate arterial vascular disease in a client who is experiencing intermittent claudication. A Doppler ultrasound is indicated for further evaluation. The bradycardic heart rate is acceptable in an athletic client with a normal blood pressure. The SpO₂ is acceptable; the client has a smoking history.

CN: Physiological adaptation; CL: Analyze

7. 2. With each set of vital signs, the nurse should assess the dorsalis pedis and posterior tibial pulses. The nurse needs to ensure adequate perfusion to the lower extremity with the drop in blood pressure. IV fluids, nasal cannula setting, and capillary refill are important to assess; however, priority is to determine the cause of drop in blood pressure and that adequate perfusion through the new graft is maintained.

CN: Reduction of risk potential; CL: Analyze

8. 1,2,3,5. Maintaining skin integrity is important in preventing chronic ulcers and infections. The client should be taught to inspect the skin on a daily basis. The client should reduce weight to promote circulation; a diet lower in calories and fat is appropriate. Because the client is receiving warfarin, the client is at risk for bleeding from cuts. To decrease the risk of cuts, the nurse should suggest that the client use an electric razor. The client with decreased arterial blood flow should be encouraged to participate in ADLs. In fact, the client should be encouraged to consult an exercise physiologist for an exercise program that enhances the aerobic capacity of the body.

CN: Health promotion and maintenance; CL: Synthesize

9. 3. Weakness, dizziness, and headache are common adverse effects of clopidogrel, and the client should report these to the **healthcare provider (HCP)**  if they are problematic; in order to decrease risk of clot formation, the drug must be taken regularly and should not be stopped or taken intermittently. The main adverse effect of clopidogrel is bleeding, which often occurs as increased bruising or bleeding when brushing teeth. Clopidogrel is well absorbed, and while food may help decrease potential

gastrointestinal upset, the drug may be taken with or without food. Clopidogrel is an antiplatelet agent used to prevent clot formation in clients who have experienced or are at risk for myocardial infarction, ischemic stroke, peripheral artery disease, or acute coronary syndrome.

CN: Pharmacological and parenteral therapies; CL: Evaluate

10. 3. Cilostazol is indicated for management of intermittent claudication. Symptoms usually improve within 2 to 4 weeks of therapy. Intermittent claudication prevents clients from walking for long periods of time. Cilostazol inhibits platelet aggregation induced by various stimuli and improving blood flow to the muscles and allowing the client to walk long distances without pain. Peripheral artery disease causes pain mainly of the leg muscles. “Aches and pains” does not specify exactly where the pain is occurring. Headaches may occur as a side effect of this drug, and the client should report this information to the **healthcare provider (HCP)** . Peripheral artery disease causes decreased blood supply to the peripheral tissues and may cause gangrene of the toes; the drug is effective when the toes are warm to the touch and the color of the toes is similar to the color of the body.

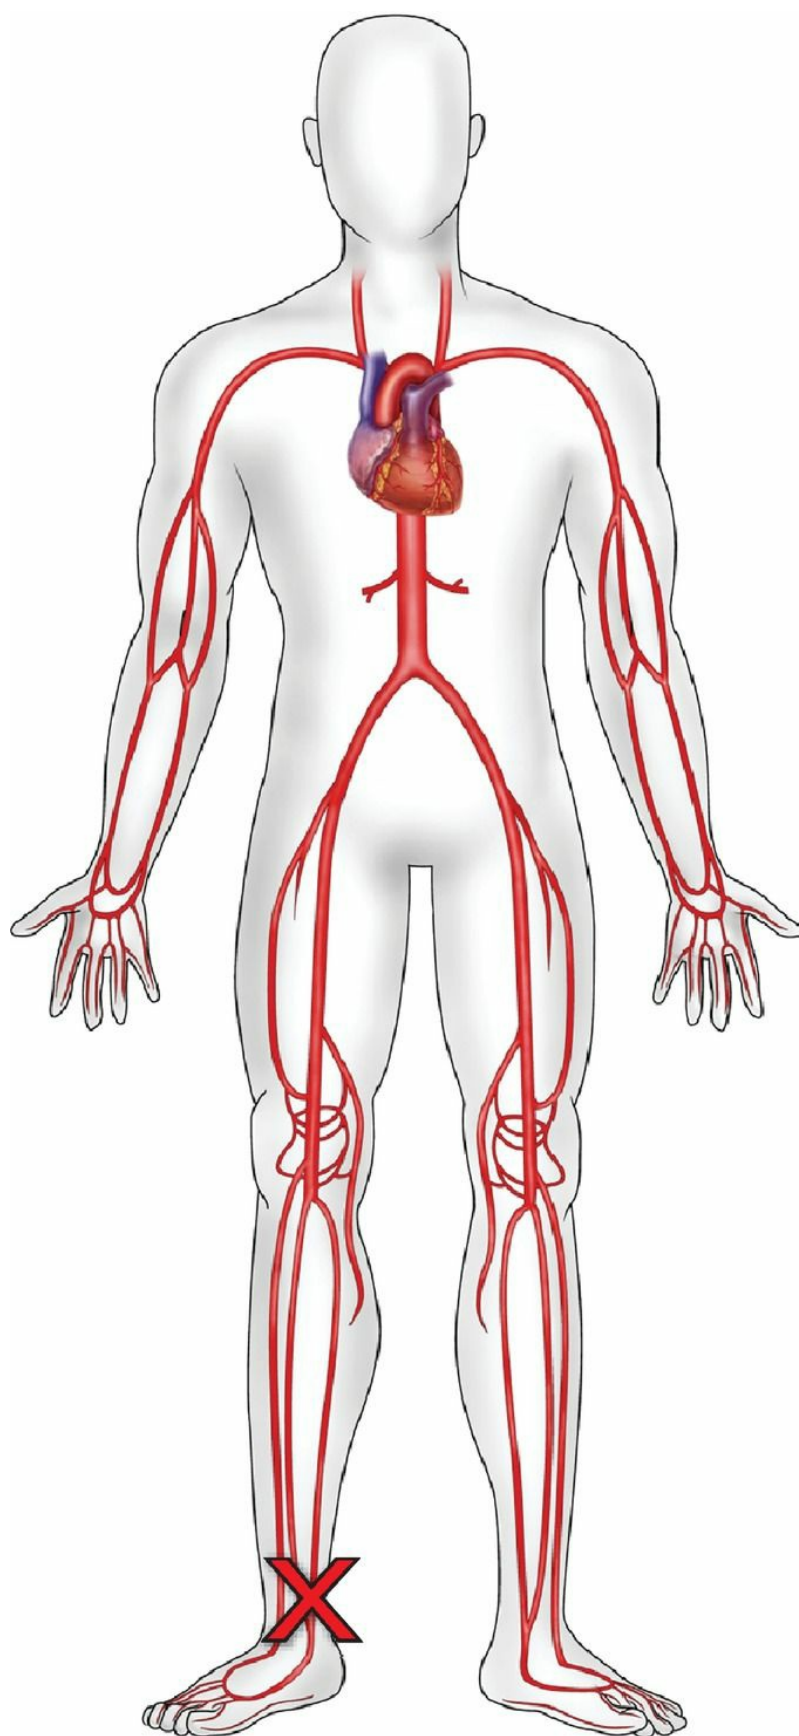

CN: Pharmacological and parenteral therapies; CL: Evaluate

11. 4. Decreased blood flow is a common characteristic of all peripheral artery disease. When the demand for oxygen to the working muscles becomes greater than the supply, pain is the outcome. The nurse should suggest that the client enroll in a supervised exercise training program that will assist the client to gradually increase walking distances without pain. Not walking and resting will not increase blood flow to the legs. Support stockings may be prescribed, but the client should improve the capacity to walk and obtain exercise.

CN: Reduction of risk potential; CL: Apply

12. The nurse palpates the dorsalis pedis; if the pulse is obtained in that artery, the tibio-peroneal artery is patent.

13. 4.

The presence of a strong dorsalis pedis pulse indicates that there is circulation to the extremity distal to the surgery indicating that the graft between the femoral and popliteal artery is allowing blood to circulate effectively. Answer 1 shows the nurse obtaining the radial pulse; answer 2 shows the femoral pulse, which is proximal to the surgery site and will not indicate circulation distal to the surgery site. Answer 3 shows the nurse obtaining an apical pulse.

 CN: Reduction of risk potential; CL: Analyze

14. 2,4. Reduction of blood flow to a specific area results in decreased oxygen and nutrients. As a result, the skin may appear mottled. The skin will also be cool to the touch. Loss of hair and dry skin are other signs that the nurse may observe in a client with peripheral artery disease of the lower extremities.

 CN: Health promotion and maintenance; CL: Analyze

15. 3. When pedal pulses are not palpable, the nurse should obtain a Doppler ultrasound device. Auscultation is not likely to be helpful if the pulse

is not palpable. Inspection of the lower extremity can be done simultaneously when palpating, but the nurse should first try to locate a pulse by Doppler. Calling the **HCP** 📖 may be necessary if there is a change in the client's condition.

🔑 CN: Physiological adaptation; CL: Synthesize

16. 4. Coldness in the left foot and ankle is consistent with complete arterial obstruction. Other expected findings would include paralysis and pallor. Aching pain, a burning sensation, or numbness and tingling are earlier signs of tissue hypoxia and ischemia and are commonly associated with incomplete obstruction.

🔑 CN: Physiological adaptation; CL: Analyze

17. 2,4,3,1. Because assessment of the presence and quality of the pedal pulses in the affected extremity is essential after surgery to make sure that the bypass graft is functioning, this step should be done **first**. The nurse should next ensure that the dressing is intact and then that the client has adequate urine output. Lastly, the nurse should determine the client's level of pain.

🔑 CN: Physiological adaptation; CL: Synthesize

18. 3. Decreasing venous congestion in the extremities is a desired outcome for clients with heart failure. The nurse should elevate the client's legs. It is not necessary for the client to return to bed. Support stockings are not indicated at this time. The client is not having difficulty breathing or other signs of distress; it is not necessary to take the vital signs.

🔑 CN: Health promotion and maintenance; CL: Synthesize

19. 3. The term *gangrene* refers to blackened, decomposing tissue that is devoid of circulation. Chronic ischemia and death of the tissue can lead to gangrene in the affected extremity. Injury, edema, and decreased circulation lead to infection, gangrene, and tissue death. Atrophy is the shrinking of tissue, and contraction is joint stiffening secondary to disuse. The term *rubor* denotes a reddish color of the skin.

🔑 CN: Physiological adaptation; CL: Analyze

20. 2. Slow, steady walking is a recommended activity for clients with

peripheral vascular disease because it stimulates the development of collateral circulation. The client with PVD should not remain inactive. Elevating the legs above the heart or wearing antiembolism stockings is a strategy for alleviating venous congestion and may worsen peripheral artery disease.

 CN: Basic care and comfort; CL: Evaluate

21. 2. Clients may have an immediate or a delayed reaction to the radiopaque dye. The **HCP**  should be notified immediately because the symptoms suggest an allergic reaction. Treatment may involve administering oxygen and epinephrine. Explaining that the procedure is over does not address the current symptoms.

 CN: Physiological adaptation; CL: Synthesize

22. 3. The client is at greater risk for skin breakdown in the lower extremities related to the edema and to remaining in one position, which increases capillary pressure. Turning the client every 1 to 2 hours promotes vasodilation and prevents vascular compression. Administering pain medication will not have an effect on skin integrity. Encouraging fluids is not a direct intervention for maintaining skin integrity, although being well hydrated is a goal for most clients. Maintaining hygiene does influence skin integrity but is secondary in this situation.

 CN: Physiological adaptation; CL: Synthesize

23. 4. The client should avoid using iodine or over-the-counter medications. Iodine is a highly toxic solution. An individual who has known PVD should be seen by a **healthcare provider (HCP)**  for treatment to avoid infection. The client with PVD should avoid heating pads and crossing the legs, and should wear leather shoes. A heating pad can cause injury, which, because of the decreased blood supply, can be difficult to heal. Crossing the legs can further impede blood flow. Leather shoes provide better protection.

 CN: Health promotion and maintenance; CL: Evaluate

24. 1. Maintaining circulation in the affected extremity after surgery is the focus of care. The graft can become occluded, and the client must be assessed

frequently to determine whether the graft is patent. Preventing infection and relieving pain are important but are secondary to maintaining graft patency. Education should have taken place in the preoperative phase and then continued during the recovery phase.

CN: Physiological adaptation; CL: Synthesize

25. 1,3. Elastic stockings (support hose) are used to promote circulation by preventing pooling of blood in the feet and legs. The stockings should be applied in the morning before the client gets out of bed. The stockings should be applied smoothly to avoid wrinkles, but the top should not be rolled down to avoid constriction of circulation. The stockings should be removed every 8 hours, and the client should elevate the legs for 15 minutes and reapply the stockings. Clean stockings should be applied daily or as needed.

CN: Health promotion and maintenance; CL: Create

26. 4. If surgery is scheduled, the nurse should avoid venipunctures in the affected extremity. The goal should be to prevent unnecessary trauma and possible infection in the affected arm. Disruptions in skin integrity and even minor skin irritations can cause the surgery to be canceled. The nurse can continue to monitor the temperature and radial pulse in the affected arm; however, doing so is not the **priority**. Keeping the client warm is important but is not the **priority** at this time.

CN: Reduction of risk potential; CL: Analyze

27. 3. Nicotine causes vasospasm and impedes blood flow. Stopping smoking is the most significant lifestyle change the client can make. The client should eat low-fat foods as part of a balanced diet. The legs should not be elevated above the heart because this will impede arterial flow. The legs should be in a slightly dependent position. Jogging is not necessary and probably is not possible for many clients with arterial occlusive disease. A rehabilitation program that includes daily walking is suggested.

CN: Health promotion and maintenance; CL: Synthesize

28. 1. A change in the intensity of a pulse may be indicative of arterial closure and warrants immediate attention; the nurse should notify the **healthcare provider (HCP)**  immediately. A pain level of 2 out of 10 is

not uncommon from the catheter insertion site especially after the placement of a stent. Shiny and hairless skin is expected in clients with PAD. A client undergoing a catheterization may experience pain at the catheterization site as large-bore sheaths are placed in the femoral artery. Because people with PAD have poor circulation in their lower extremities, it is possible for them to develop leg ulcers. However, it is unlikely that the percutaneous transluminal balloon angioplasty caused this.

CN: Physiological adaptation; CL: Analyze

29. 1,2,5. Turning frequently promotes circulation, while using pillows for support will prevent stress to the suture line. Short periods of different leg/body positions will not impair postoperative oxygen levels. The client should only be in a knee-flexed position when walking and not at rest. Prolonged sitting is discouraged, and it may cause pain and edema. It is not recommended that the leg be placed in a dependent position as this promotes edema. Placing a client in a supine position with the leg elevated above the heart is recommended only if the client develops edema.

CN: Physiological adaptation; CL: Synthesize

30. 4. Diltiazem is a calcium channel blocker that blocks the influx of calcium into the cell. In this situation, the primary use of diltiazem is to promote vasodilation and prevent spasms of the arteries. As a result of the vasodilation, blood, oxygen, and nutrients can reach the muscle and tissues. Diltiazem is not an antianxiety agent and does not promote sedation. It also does not cause vasoconstriction, which would be contraindicated for the client with peripheral vascular disease.

CN: Pharmacological and parenteral therapies; CL: Evaluate

31. 1. Although pentoxifylline's precise mechanism of action is unknown, its therapeutic effect is to increase blood flow, and the client should have improved circulation in the legs as evident by less pain. The client does not have nerve impairment and should be able to wiggle the toes. Urination is not improved by taking pentoxifylline. Dizziness is a side effect of the drug, not an intended outcome.

CN: Pharmacological and parenteral therapies; CL: Evaluate

32. 4. Pentoxifylline can potentiate the effects of theophylline and increase the risk of theophylline toxicity. Therefore, the nurse should monitor the client's theophylline level. Pentoxifylline does not interact with digoxin. Pentoxifylline can interact with heparin, and the client's PTT would need to be monitored closely if the client were taking heparin. It does not affect cholesterol levels.

CN: Pharmacological and parenteral therapies; CL: Analyze

33. 2. Angina is an adverse reaction to pentoxifylline, which should be used cautiously in clients with CAD. The nurse should report the client's symptoms to the **HCP**,  who may prescribe nitroglycerin and possibly discontinue the pentoxifylline. The client should rest until the chest pain subsides. It is not necessary at this point to initiate the **rapid response team**  or start an intravenous infusion. The client's reports of symptoms should never be dismissed.

CN: Physiological adaptation; CL: Synthesize

34. 1. Assessing the individual's health behavior before surgery will help the nurse and client develop strategies to manage the postoperative course. Asking open-ended questions will elicit the most helpful information. The client's ability to walk will be improved after surgery. The client should report any changes in urination, but urinary retention is not expected before or after surgery.

CN: Health promotion and maintenance; CL: Create

35. 4. Before beginning dietary interventions, the nurse must assess the client's pattern of food intake, lifestyle, food preferences, and ethnic, cultural, and financial influences. With this information, the nurse can then discuss the client's knowledge about cholesterol, foods high in fat, cholesterol and sodium, and coach the client about the importance of following the diet plan.

CN: Basic care and comfort; CL: Synthesize

The Client with Peripheral Vascular Disease Having an Amputation

36. 2. Encouraging the client who is undergoing amputation to verbalize feelings is the **most** therapeutic nursing intervention. By eliciting concerns, the nurse may be able to provide information to help the client cope. The nurse should avoid value-laden responses, such as “You will still have one good leg,” that may make the client feel guilty or hostile and block further communication. The nurse should not ignore the client’s expressed concerns, nor should the nurse reinforce the client’s concern about invalidism and dependency or assume that his wife is willing to care for him.

 CN: Psychosocial integrity; CL: Synthesize

37. 2. The level of amputation commonly cannot be accurately determined until surgery, when the surgeon can directly assess the adequacy of the circulation of the residual limb. A longer residual limb facilitates prosthesis fitting and will make it easier for the client to walk. However, although these aspects will be considered in the final decision, they are not the primary factors influencing the decision.

 CN: Physiological adaptation; CL: Synthesize

38. 1. Leg crossing is contraindicated because it causes adduction of the hips and decreases the flow of blood into the lower extremities. This may result in increased pressure in the graft in the affected leg. Elevating the legs, flexing the ankles, and extending the knees are not necessarily contraindicated.

 CN: Reduction of risk potential; CL: Synthesize

39. 2. The client should be evaluated for hemodynamic stability and extent of bleeding prior to calling the **HCP**.  Direct pressure can be used prior to applying a tourniquet if there is significant bleeding. To avoid flexion contractures, which can delay rehabilitation, elevation of the surgical limb is contraindicated.

 CN: Reduction of risk potential; CL: Synthesize

40. 3. The purpose of wrapping the residual limb is to shape the residual limb to accept a prosthesis and bear weight. The compression bandaging should be worn at all times for many weeks after surgery and should be reapplied as needed to keep it free of wrinkles and snug. The dressing should

be changed daily to allow for inspection of the stump incision. No lotions should be applied to the stump unless specifically prescribed by the **healthcare provider (HCP)** 📖. The stump should not be elevated on pillows because this will contribute to the formation of flexion contractures. Contractures will prevent the client from wearing a prosthesis and ambulating.

🔑 CN: Physiological adaptation; CL: Evaluate

The Client with an Aneurysm

41. 4. The underlying pathophysiology in this client is atherosclerosis. The findings from the assessment indicate the risk factors of smoking and high blood pressure. Therefore, tissue perfusion is a **priority** for health-promoting education. The data do not support education that focuses on food or fluid intake. Although edema is a potential problem and could contribute to poor skin integrity, the edema will likely be resolved by the aneurysm repair.

🔑 CN: Physiological adaptation; CL: Synthesize

42. 1. The size of the thoracic aneurysm is rather large, so the nurse should anticipate rupture. A sudden incidence of pain may indicate leakage or rupture. The blood pressure and heart rate will provide useful information in assessing for hypovolemic shock. The nurse needs more data before initiating other interventions. After assessment of vital signs, neurologic status, and pain, the nurse can then contact the **HCP**. 📖

🔑 CN: Physiological adaptation; CL: Synthesize

43. 2,4,3,1. The data suggest an abdominal aortic aneurysm that is leaking or rupturing. When implementing the prescriptions, the nurse should **first** establish an intravenous infusion with a large-bore needle for immediate volume replacement. Next, the nurse should insert the nasogastric tube to relieve the nausea and vomiting and decompress the stomach. The nurse next should administer pain medication. Last, the nurse should monitor intake and output; with hypovolemia, the urine output will be diminished.

🔑 CN: Physiological adaptation; CL: Synthesize

44. 4. One of the complications of a thoracoabdominal aneurysm repair is

spinal cord injury. Therefore, it is important for the nurse to assess for signs and symptoms of neurologic changes at and below the site where the aneurysm was repaired. The client is expected to have moderate pain following surgery. An elevated heart rate is expected after physical exertion. It is important to monitor urine output following aneurysm surgery, but a urine output of 2,000 mL in 24 hours is adequate following surgery.

 CN: Safety and infection control; CL: Synthesize

45. 3. The primary goal is to prepare the client for emergency surgery. The goal would be to prevent rupture of the aneurysm and potential death. Circulation is maintained, unless the aneurysm ruptures. When the client is prepared for surgery, the nurse should place the client in a recumbent position to promote circulation, teach the client about postoperative breathing exercises, and administer pain medication if prescribed.

 CN: Physiological adaptation; CL: Synthesize

46. 1. Cardiac tamponade is a life-threatening complication of a dissecting thoracic aneurysm. The sudden, painful “tearing” sensation is typically associated with the sudden release of blood, and the client may experience cardiac arrest. Stroke, pulmonary edema, and myocardial infarction are not common complications of a dissecting aneurysm.

 CN: Physiological adaptation; CL: Apply

47. 1. Following surgical repair of an aortic aneurysm, there is a potential for an alteration in renal perfusion, manifested by decreased urine output. The altered renal perfusion may be related to renal artery embolism, prolonged hypotension, or prolonged aortic cross-clamping during surgery. Electrolyte imbalance and anxiety do not present imminent risk for this client; signs of wound infection are generally not evident immediately following surgery, but the nurse should monitor the incision on an ongoing basis.

 CN: Physiological adaptation; CL: Analyze

48. 4. The client is experiencing paralytic ileus. One of the adverse effects of morphine used to manage pain is decreased GI motility. Bowel manipulation and immobility also contribute to a postoperative ileus. Insertion of an NG tube generally prevents a postoperative ileus. The ice

chips and IV fluids will not affect the ileus.

CN: Basic care and comfort; CL: Analyze

49. 3. The client with a synthetic graft may need to be treated with prophylactic antibiotics before undergoing major dental work. This reduces the danger of systemic infection caused by bacteria from the oral cavity. Venous access for drawing blood, IV line insertion, and x-rays do not contribute to the risk of infection.

CN: Pharmacological and parenteral therapies; CL: Synthesize

50. 3. A blood pressure of 80/50 mm Hg in a client who has just had surgical repair of an abdominal aortic aneurysm warrants further evaluation as this indicates decreased perfusion to the brain, heart, and kidneys. A BUN of 26 and a creatinine of 1.2 are normal findings. While +1 pedal pulses may be an abnormal finding, it is not uncommon, and it is important to compare this finding to previous assessments and note if this is a change of the strength of the pedal pulses. Absent bowel sound and mild abdominal distension are expected for a client immediately following surgery. However, this finding should be monitored as it could indicate a paralytic ileus.

CN: Physiological adaptation; CL: Analyze

51. 4. A blood transfusion is required postoperatively with significant blood loss from surgery or bleeding. Data from the progress notes indicate the client is hypovolemic and has a low hemoglobin level, which warrants transfusion at this time rather than IV fluids. The nurse must continue to assess the client for signs of bleeding. Correction of hypovolemia precedes a dopamine infusion. The transfusion should improve the hemodynamics, and the hemoglobin and hematocrit are reassessed post transfusion. The client has fluid volume deficit, so furosemide is not needed at this time.

The Client with Raynaud's Phenomenon

52. 3. Clients with Raynaud's phenomenon should receive routine follow-up to monitor symptoms and to assess for the development of connective tissue or autoimmune diseases associated with Raynaud's. Beta-blockers are not considered first-line drug therapy. A sympathectomy is considered only

in advanced cases. There is no benefit to an angioplasty, which is used for atherosclerotic vascular disease.

 CN: Health promotion and maintenance; CL: Create

53. 1,2,5. Vasospastic disorder (Raynaud's disease) is a form of intermittent arteriolar vasoconstriction that results in coldness, pain, and pallor of the fingertips, toes, or tip of the nose, and a rebound circulation with redness and pain. The nurse should instruct the client to stop smoking because nicotine is a vasoconstrictor. An adverse effect of reserpine is orthostatic hypotension. The client should report dizziness and low blood pressure as it may be necessary to consider stopping the drug. The client should prevent vasoconstriction by covering affected parts when in cold environments. The nurse can teach the client to rewarm exposed extremities by using warm water or placing them next to the body, such as under the axilla. It is not realistic to ask this client to change jobs at this time.

 CN: Health promotion and maintenance; CL: Create

54. 2. The client has numbness in the fingertips, and the nurse should **first** help the client regain sensory perception and discuss strategies for prevention of injury. The client does not have acute pain. The client does have adequate circulation and is not at risk for skin breakdown at this time.

 CN: Physiological adaptation; CL: Analyze

55. 1. Vasospastic disorder (Raynaud's disease) is more common in young women and is associated with collagen diseases such as rheumatoid arthritis and lupus.

 CN: Physiological adaptation; CL: Analyze

56. 3. Initially, the vasoconstriction effect produces pallor or a whitish coloring, followed by cyanosis (bluish) and finally rubor (red). Gangrene is the end result of complete arterial occlusion; the skin is blackened and without a blood supply.

 CN: Reduction of risk potential; CL: Analyze

57. 2. Decreased perfusion from vasospasm induces color changes in the extremity. The degree of decreased perfusion should be assessed by taking

the radial pulse. Color changes progressively to blue with cyanosis and then red when reperfusion occurs. The SpO₂ requires adequate perfusion for accuracy. A blood pressure will cause further constriction and reduction of perfusion in the extremity.

CN: Physiological adaptation; CL: Analyze

58. 3. Extreme changes in temperature can precipitate a vasospastic episode and should be avoided by clients with vasospastic disorder (Raynaud's disease). The client should be encouraged to wear gloves when handling frozen foods or ice. The client should immerse the involved extremity in warm water during an episode to promote vasodilation and relaxation of the small arteries that are in spasm. The client can help prevent vasospasm brought on by temperature changes by wearing warm clothes. Living in a cold climate will exacerbate the symptoms.

CN: Health promotion and maintenance; CL: Synthesize

59. 3. Loose warm clothing should be worn to protect from the cold. Wearing gloves when handling cold objects will help prevent vasospasms. Vibrating equipment and typing contribute to vasospasm. Tobacco and caffeine should be avoided. Elevation will decrease arterial perfusion during vasospasms.

CN: Health promotion and maintenance; CL: Synthesize

60. 3. Calcium channel blockers are first-line drug therapy for the treatment of vasospasms with Raynaud's phenomenon when other therapies are ineffective. Diltiazem relaxes smooth muscles and improves peripheral perfusion, thereby reducing finger numbness. Diltiazem decreases heart rate and is used to treat atrial fibrillation, but these are not associated with Raynaud's. When vasospasms are prevented, an accurate SpO₂ can be measured in the affected extremity; however, SpO₂ is a measurement of systemic oxygenation not influenced by diltiazem.

CN: Pharmacological and parenteral therapies; CL: Evaluate

61. 1. Beta-adrenergic medications block the beta-adrenergic receptors. Therefore, the expected outcome of the medication is to decrease the influence of the sympathetic nervous system on the blood vessels in the

hands. Beta-adrenergic blockers have no analgesic effects. Increasing blood supply to the affected area is an indirect effect of beta-adrenergic blockers. They do not increase monoamine oxidase, which does not play a role in Raynaud's disease.

CN: Pharmacological and parenteral therapies; CL: Apply

62. 4. Sympathectomy is scheduled only after other treatment alternatives have been explored and have failed. Medication and stress management are beneficial strategies to prevent advancement of the disease process. If the disease is controlled by medication, there is no reason for surgery.

CN: Physiological adaptation; CL: Apply

The Client with Peripheral Venous Disease: Thrombophlebitis, Deep Vein Thrombosis, and Embolus Formation

63. 4. Based on the laboratory findings, prothrombin time and INR are at acceptable anticoagulation levels for the treatment of DVT. However, the platelets are below the acceptable level. Clients taking enoxaparin are at risk for thrombocytopenia. Because of the low platelet level, the nurse should withhold the enoxaparin and contact the **HCP**.  The nurse should not administer the drug until the HCP has been contacted. The HCP, not the pharmacist, will make the decision about the dose of the enoxaparin. The decision about administering the drug will be based on laboratory results, not evidence of bruising or bleeding.

CN: Pharmacological and parenteral therapies; CL: Synthesize

64. 1. Elevating the head of the bed facilitates breathing because the lungs are able to expand as the diaphragm descends. Coughing and deep breathing do not alleviate the symptoms of a pulmonary embolus, nor does lung auscultation. The **HCP**  must be kept informed of changes in a client's status, but the priority in this case is alleviating the symptoms.

CN: Reduction of risk potential; CL: Synthesize

65. 1. A client with deep vein thrombosis (DVT) is at high risk for a

pulmonary embolism from an embolus traveling to the lung. Sudden onset of symptoms and worsening of chest pain with a deep breath suggest a pulmonary embolism. The nurse assesses the client and obtains oxygen saturation levels prior to calling the **HCP** 📖 and administering morphine. Range of motion is a preventive measure for DVT and is not appropriate at this time.

🔑 CN: Reduction of risk potential; CL: Synthesize

66. 2. Acute arterial occlusion is a sudden interruption of blood flow. The interruption can be the result of complete or partial obstruction. Acute pain, loss of sensory and motor function, and a pale, mottled, numb extremity are the most dramatic and observable changes that indicate a life-threatening interruption of tissue perfusion. Blood pressure and heart rate changes may be associated with the acute pain episode. Metabolic acidosis is a complication of irreversible ischemia. Swelling may result but may also indicate venous stasis or arterial insufficiency.

🔑 CN: Physiological adaptation; CL: Analyze

67. 1. Venous stasis can increase pain. Therefore, proper positioning in bed with the foot of the bed elevated or when sitting up in a chair can help promote venous drainage, reduce swelling, and reduce the amount of pain the client might experience. Placing a pillow under the knees causes flexion of the joint, resulting in a dependent position of the lower leg and causing a decrease in blood flow. Fluids are encouraged to maintain normal fluid and electrolyte balance but do little to relieve pain. Therapeutic massage to the legs is discouraged because of the danger of breaking up the clot.

🔑 CN: Basic care and comfort; CL: Synthesize

68. 3. The client is likely suffering from an embolus as a result of abdominal surgery. The nurse should inspect the left leg for color and temperature changes associated with tissue perfusion. Administering pain medication without gathering more information about the pain can mask important signs and symptoms. Although assessing for edema is important, it is not critical to this situation. Encouraging the client to change her position does not adequately address the need for gathering more data.

 CN: Reduction of risk potential; CL: Synthesize

69. 2. Performing active ankle and foot range-of-motion exercises periodically during the ride home will promote muscular contraction and provide support to the venous system. It is the muscular action that facilitates return of the blood from the lower extremities, especially when in the dependent position. Arm circle exercises will not promote circulation in the leg. It is not necessary for the client to elevate the legs as long as the client does not occlude blood flow to the legs and does the leg exercises. It is not necessary to take an ambulance because the client is able to sit in the car safely.

 CN: Reduction of risk potential; CL: Synthesize

70. 3. Thrombolytic agents such as streptokinase are used for clients with a history of thrombus formation, cerebrovascular accidents, and chronic atrial fibrillation. The thrombolytic agents act by dissolving emboli. Thrombolytic agents do not directly improve perfusion or increase vascular permeability, nor do they prevent cerebral hemorrhage.

 CN: Pharmacological and parenteral therapies; CL: Evaluate

71. 0.85 mL. The prescription is for the client to receive enoxaparin 1 mg/kg. Therefore, the client is to receive 85 mg. The desired dose in milliliters then can be calculated by using the formula of desired dose (D) divided by dose or strength of dose on hand (H) times volume (V).

$$85(\text{mg}) \times 0.3 \text{ mL} = 25.5 \text{ mg} / \text{mL}$$

$$25.5 \text{ mg} \div 30 = 0.85 \text{ mL}$$

 CN: Pharmacological and parenteral therapies; CL: Apply

72. 4. Thrombophlebitis is an inflammation of a vein. The underlying etiology involves stasis of blood, increased blood coagulability, and vessel wall injury. The symptoms of thrombophlebitis are pain, swelling, and deep muscle tenderness. Air embolus is a result of air entering the vascular system. Fat embolus is associated with the presence of intracellular fat globules in the

lung parenchyma and peripheral circulation after long-bone fractures. Stress fractures are associated with the musculoskeletal system.

CN: Health promotion and maintenance; CL: Analyze

73. 2. Localized pain, tenderness, redness, and warmth may be symptoms of deep vein thrombosis (DVT), information the nurse should report to the **HCP**;  the compression devices should not be applied until further evaluation is completed as intermittent compression may dislodge a thrombus. Massaging the area may dislodge a thrombus and is not recommended. The nurse may offer PRN analgesics if the client requires pain management, but the compression devices should not be applied until further evaluation is completed. Diagnosis and treatment of DVT should be discussed with the HCP as soon as possible; the nurse should not wait until the next shift to report findings as a DVT can become life threatening if a thrombus travels to the lung and becomes a pulmonary embolus.

CN: Reduction of risk potential; CL: Synthesize

74. 3. The first action should be to discontinue the IV. The nurse should restart the IV elsewhere and then apply a warm compress to the affected area. The nurse should administer acetaminophen or an anti-inflammatory agent only if prescribed by the **healthcare provider (HCP)** . The type of - infusion cannot be changed without an HCP's prescription, and such a change would not help in this case.

CN: Reduction of risk potential; CL: Synthesize

75. 4. Three factors contribute to the formation of venous thrombus and thrombophlebitis: damage to the inner lining of the vein (prolonged pressure), hypercoagulability of the blood, and venous stasis. Bed rest and immobilization are associated with decreased blood flow and venous pooling in the lower extremities. Keeping the client in the supine position would not be appropriate. Turning the client every 1 to 2 hours, passive and active range-of-motion exercises, and use of TED hose help prevent venous stasis in the lower extremities.

CN: Reduction of risk potential; CL: Create

76. 2. The client demonstrates classic symptoms of DVT, and the nurse

should continue to assess the client. Signs and symptoms of an aortic aneurysm include abdominal pain and a pulsating abdominal mass. Clients with drug abuse demonstrate confusion and decreased levels of consciousness. Claudication is an intermittent pain in the leg.

 CN: Psychosocial integrity; CL: Analyze

77. 4. Heparin dosage is usually determined by the **healthcare provider (HCP)**  based on the client's aPTT and INR laboratory values. Therefore, the nurse monitors these values to prevent complications. Administering aspirin when the client is on heparin is contraindicated. Green leafy vegetables are high in vitamin K and therefore are not recommended for clients receiving heparin. Monitoring of the client's PT is done when the client is receiving warfarin sodium.

 CN: Pharmacological and parenteral therapies; CL: Create

78. 4. The use of pneumatic compression stockings is an intervention used to prevent DVT. Other strategies include early ambulation, leg exercises if the client is confined to bed, adequate fluid intake, and administering anticoagulant medication as prescribed. Deep breathing would be encouraged postoperatively, but it does not prevent DVT.

 CN: Health promotion and maintenance; CL: Synthesize

79. 360 mL

$$25,000 \text{ U} / 500 \text{ mL} = 50 \text{ U} / \text{mL}$$

$$1 \text{ mL} / 50 \text{ U} \times 1500 \text{ U} / \text{h} = 30 \text{ mL} / \text{h} \times 12 \text{ h} \\ = 360 \text{ mL}$$

 CN: Pharmacological and parenteral therapies; CL: Apply

80. 4. The data suggest an increased risk of thrombophlebitis. The risk factors in this situation include abdominal surgery, obesity, and use of estrogen-based oral contraceptives. Risk factors for atherosclerosis include genetics, older age, and a high-cholesterol diet. Risk factors for diabetes include genetics and obesity. Risk factors for vasospastic disorders include

cold climate, age (16 to 40), and immunologic disorders.

CN: Reduction of risk potential; CL: Analyze

81. 2. The client is at risk for development of varicose veins. Therefore, prevention is key in the treatment plan. Maintaining ideal body weight is the goal. In order to achieve this, the client should consume a balanced diet and participate in a regular exercise program. Performing leg lifts improves muscle strength, but it is more important for the client to increase exercise by walking. Wearing support stockings is helpful to promote circulation, but the client should not roll the stockings at the top to hold the stockings up as this will decrease circulation at the knees.

CN: Reduction of risk potential; CL: Evaluate

82. 1,2,4,5,6. Clients with resolving DVT being sent home on anticoagulant therapy need instructions about assessing and preventing bleeding episodes and preventing a recurrence of DVT. Blood in the urine (hematuria) is often one of the first symptoms of anticoagulant overdose. Fresh blood in the urine is red; however, blood in the urine may also be a dark smoky color. Daily ambulation is an excellent activity to keep the venous blood circulating and thus to prevent blood clots from forming in the lower extremities. Garlic and ginger increase the bleeding time and should not be used when a client is on anticoagulant therapy. Clients who have had previous DVTs should avoid activities that cause stagnation and pooling of venous blood. Prolonged sitting coupled with change of air pressure without foot or leg exercises or ambulation in the cabin are activities that prevent venous return. Instructing the client about prevention measures is important because clients with DVT are at high risk for pulmonary emboli (PE), which can be fatal. The client can be taught risk factors for DVT and PE. In addition, recommendations for prevention of these events also are standard protocol in practice and should be shared with the client for home care purposes. Older adults should be monitored closely for bleeding because the skin becomes thinner and the capillaries become more fragile with the aging process.

CN: Health promotion and maintenance; CL: Create

83. 4,5,3,1,2. The nurse should first monitor the popliteal and the pedal

pulses in the affected extremity after arterial embolectomy. Monitoring peripheral pulses below the site of occlusion checks the arterial circulation in the involved extremity. The nurse should next inspect the dressing to be sure that the client is not bleeding at the surgical site. The nurse should next regulate the IV infusion to prevent fluid overload. Then the nurse should assess pain and administer pain medications as prescribed. Last, the nurse can obtain blood for laboratory studies.

CN: Physiological adaptation; CL: Synthesize

84. 2. These symptoms suggest that the client is receiving too much warfarin; the client should return to the laboratory and have a blood sample drawn to determine the prothrombin levels and have the dosage of warfarin adjusted. The diet can influence clotting, but the client needs to first have the prothrombin levels checked. It is not necessary to contact the HCP;  the client should return to the laboratory first, and the results of the prothrombin time will be reported to the HCP.

CN: Pharmacological and parenteral therapies; CL: Evaluate

The Client with Varicose Veins

85. 2. The nurse instructs the client to elevate the legs to improve venous return and alleviate discomfort. Walking is encouraged to increase venous return. Sclerotherapy or laser treatment is done for cosmetic reasons, but it does not improve circulation. Surgery may be performed for severe venous insufficiency or recurrent thrombophlebitis in the varicosities. Femoral-popliteal bypass graft is a surgical intervention for arterial disease.

CN: Health promotion and maintenance; CL: Synthesize

86. 3. Secondary varicosities can result from previous thrombophlebitis of the deep femoral veins, with subsequent valvular incompetence. Cerebrovascular accident, anemia, and transient ischemic attacks are not associated with an increased risk of varicose veins.

CN: Health promotion and maintenance; CL: Analyze

87. 1. Sclerotherapy involves injecting small- and medium-sized varicose veins with a solution that scars and closes those veins. In a few weeks, the

veins should fade and disappear. This procedure does not require anesthesia and can be done in a **healthcare provider's (HCP's)** office. Varicose veins can reoccur regardless of the procedure. Bruising is more likely following vein stripping or catheter-assisted procedures.

CN: Physiological adaptation; CL: Application

88. 1,2,4. To manage varicose veins, the nurse should coach the client to lose weight to relieve pressure on the veins, wear compression stockings to promote circulation, and elevate the legs when sitting or lying down. Applying lotion to the veins will keep the skin moist, but does not promote venous circulation. Pillows under the knees will obstruct circulation.

CN: Health promotion and maintenance; CL: Create

The Client with Stasis Ulcers

89. 1,2,4,5. The underlying pathophysiology in stasis ulcers of the skin surface is a result of inadequate oxygen and other nutrients to the tissues because of edema and decreased circulation. The nurse should first initiate care that will increase oxygen and improve tissue integrity. It is also important to prevent trauma to the tissues and prevent infections, which result from decreased microcirculation that limits the body's response to infection. Stasis ulcers are painful. The nurse can administer prescribed analgesics 30 minutes before changing the dressing. There is no indication that the client's overall nutrition needs to be improved.

CN: Physiological adaptation; CL: Create

90. 1. The result of chronic venous stasis is swelling and edema and superficial varicose veins. Diuretics will help reduce the swelling, thus improving capillary circulation. Although diuretics may decrease blood pressure, that is not the intended outcome of this drug. The nurse should teach the client to prevent infection and monitor wound healing, but these are not the primary outcomes of chlorothiazide.

CN: Pharmacological and parenteral therapies; CL: Evaluate

91. 4. The nurse should keep bed linens off of the stasis ulcer to decrease the amount of pressure that the linens exert upon the lower extremity and

prevent further tissue breakdown. Administering prescribed analgesics would be an intervention for reducing the pain. Applying lanolin lotions to the left ankle ulcer will not promote healing. Encouraging the client to sit up in a chair four times per day is an intervention to promote activity. The nurse would elevate the involved extremity while the client is sitting up to reduce venous stasis and capillary pressure.

CN: Health promotion and maintenance; CL: Synthesize

92. 2. The nurse should first determine how the client will apply an herb mixture to the ulcer. The nurse should then encourage the client to consult the **healthcare provider (HCP)**  because home remedies may be beneficial or may interfere with the medical treatment plan. In many cultures, home remedies are commonly used and may be helpful. The nurse must be sensitive to these traditions and cultural beliefs. The other statements demonstrate that the client understands the plan of care for the ulcer.

CN: Pharmacological and parenteral therapies; CL: Evaluate

Managing Care, Quality, and Safety for Clients with Vascular Disease

93. 3. It is important for the nurse to assess the client with peripheral artery disease (PAD) returning from an angiogram. It will be important to make baseline assessments on this client. A client with atrial fibrillation with a heart rate of 90 bpm is not an abnormal finding. A “fluttering feeling” is expected in a client with atrial fibrillation. A client with heart failure experiencing right upper quadrant fullness does not require urgent attention; the client might be experiencing signs and symptoms of hepatomegaly.

CN: Management of care; CL: Analyze

94. 3. The client is experiencing a rebound tachycardia from abrupt withdrawal of the beta-blocker. The beta-blocker should be restarted due to the tachycardia, history of hypertension, and the desire to reduce the risk of postoperative myocardial morbidity. The bypass surgery should correct the claudication and need for pentoxifylline. The furosemide and increase in fluids are not indicated since the client’s urine output and blood pressure are satisfactory and there is no indication of bleeding. The nurse should also

determine the potassium level before starting the furosemide.

CN: Management of care; CL: Synthesize

95. 1. The nurse is the client's advocate in planning for pain relief. When presented with a communications conflict, the nurse should first restate the concern, providing as much information as needed. If the **HCP**  still does not offer an acceptable solution for pain management, the nurse can then discuss the situation with the hospitalist on the team and report the incident to the team leader. Waiting until the next shift to handle the problem does not contribute to the goal of managing the client's pain.

CN: Safety and infection control; CL: Synthesize

96. 1. The **LPN/VN**  can complete the assessment sheet and care for the client before surgery. Clients who are stable and requiring complete care or frequent assistance with basic care needs along with vital signs and intake and output recordings can be assigned to a **UAP**.  An unstable client requiring critical assessments receives care from the **RN**. 

CN: Management of Care; CL: Synthesize

97. 1,2,3,5. When obtaining blood samples, the nurse must use two acceptable sources of identification (the client states his/her name; the nurse verifies the client's name and identification number of the armband); verifying a room number is not acceptable as clients can be easily reassigned to other rooms. The client must be awake to state his/her name. Blood samples must be labeled in front of the client.

CN: Safety and infection control; CL: Synthesize

98. 1. Before starting a heparin infusion, it is essential for the nurse to know the client's baseline blood coagulation values (hematocrit, hemoglobin, and red blood cell and platelet counts). In addition, the partial thromboplastin time should be monitored closely during the process. The client's stools would be tested only if internal bleeding is suspected. Although monitoring vital signs such as apical pulse is important in assessing potential signs and symptoms of hemorrhage or potential adverse reactions to the medication, vital signs are not the most important data to collect before administering the heparin. Intake and output are not important assessments for heparin

administration unless the client has fluid and volume problems or kidney disease.

CN: Safety and infection control; CL: Synthesize

99. 4. Several variables make this client a high fall risk including secondary diagnosis of diabetes (15); intermittent IV antibiotics (20); and mental status changes (15) possibly due to anesthesia, pain, or recent limb loss. This client's assessment may clearly change as the effects of anesthesia wear off, pain is controlled, and the client becomes accustomed to ambulating with a prosthesis; because assessments may be continually changing, in most acute care facilities, a fall risk is completed every 24 hours and, sometimes, every shift.

CN: Safety and infection control; CL: Apply

TEST

3

The Client with Hematologic Health Problems

- The Client with Red Blood Cell Disorders
- The Client with Platelet Disorders
- The Client with White Blood Cell Disorders
- The Client with Lymphoma
- The Client Who Is in Shock
- Managing Care, Quality, and Safety for Clients with Hematologic Health Problems
- Answers, Rationales, and Test-Taking Strategies

The Client with Red Blood Cell Disorders

1. The nurse is assisting with a bone marrow aspiration and biopsy. In which order, from first to last, should the nurse complete these tasks? All options must be used.

1. Position the client in a side-lying position.

2. Clean the skin with an antiseptic solution.

3. Verify the client has signed an informed consent.

4. Apply ice to the biopsy site.

2. A client with iron deficiency anemia is refusing to take the prescribed oral iron medication because the medication is causing nausea; the client is also constipated. What actions should the nurse take? Select all that apply.

- ☐ 1. Suggest that the client use ginger when taking the medication.
- ☐ 2. Ask the client what is causing the nausea.
- ☐ 3. Tell the client to use stool softeners to minimize constipation.
- ☐ 4. Offer to administer the medication by an intramuscular injection.
- ☐ 5. Suggest that the client take the iron with orange juice.

3. A client had a mastectomy followed by chemotherapy 6 months ago. She reports that she is now “unable to concentrate at her card game” and “it seems harder and harder to finish her errands because of exhaustion.” Based on this information, the nurse should suggest that the client:

- ☐ 1. take frequent naps.
- ☐ 2. limit activities.
- ☐ 3. increase fluid intake.
- ☐ 4. avoid contact with others.

4. A client is to have a transfusion of packed red blood cells from a designated donor. The client asks if any diseases can be transmitted by this donor. The nurse should inform the client that which diseases can be transmitted by a designated donor? Select all that apply.

- ☐ 1. Epstein-Barr virus
- ☐ 2. human immunodeficiency virus (HIV)
- ☐ 3. cytomegalovirus (CMV)
- ☐ 4. hepatitis A
- ☐ 5. malaria

5. The nurse is preparing to teach a client with iron deficiency anemia about the diet to follow after discharge. Which food should be included in the

diet?

- ☐ 1. eggs
- ☐ 2. lettuce
- ☐ 3. citrus fruits
- ☐ 4. cheese

6. The nurse should instruct the client with vitamin B₁₂ deficiency to eat which foods to obtain the **best** supply of vitamin B₁₂?

- ☐ 1. whole grains
- ☐ 2. green leafy vegetables
- ☐ 3. meats and dairy products
- ☐ 4. broccoli and Brussels sprouts

7. The nurse has just admitted a 35-year-old female client who has a serum vitamin B₁₂ concentration of 800 pg/mL (590 pmol/L). Which laboratory findings should alert the nurse to focus the health history to obtain specific information about drug or alcohol use?

- ☐ 1. total bilirubin, 0.3 mg/dL (5.1 µmol/L)
- ☐ 2. serum creatinine, 0.5 mg/dL (44.2 µmol/L)
- ☐ 3. hemoglobin, 16 g/dL (160 g/L)
- ☐ 4. folate, 1.5 ng/mL (3.4 nmol/L)

8. Which lab values should the nurse report to the healthcare provider (HCP) when the client has anemia?

- ☐ 1. Schilling test result, elevated
- ☐ 2. intrinsic factor, absent
- ☐ 3. sedimentation rate, 16 mm/h
- ☐ 4. red blood cells (RBCs) within normal range

9. The nurse is developing a teaching plan for the client with aplastic anemia. Which is **most** important to include the plan?

- ☐ 1. Eat animal protein and dark green, leafy vegetables every day.
- ☐ 2. Avoid exposure to others with acute infections.
- ☐ 3. Practice yoga and meditation to decrease stress and anxiety.
- ☐ 4. Get 8 hours of sleep at night, and take naps during the day.

10. A client had a resection of the terminal ileum 3 years ago. While obtaining a health history and physical assessment, the nurse finds that the client has weakness, shortness of breath, and a sore tongue. Which additional information from the client indicates a need for client teaching?

- ☐ 1. "I have been drinking plenty of fluids."
- ☐ 2. "I have been gargling with warm salt water for my sore tongue."
- ☐ 3. "I have regular bowel movements on most days."
- ☐ 4. "I take a vitamin B₁₂ tablet every day."

11. A client who follows a vegetarian diet was referred to a dietitian for nutritional counseling for anemia. Which client outcome indicates that the client does **not** understand nutritional counseling? The client:

- ☐ 1. adds dried fruit to cereal and baked goods.
- ☐ 2. cooks tomato-based foods in iron pots.
- ☐ 3. drinks coffee or tea with meals.
- ☐ 4. adds vitamin C to all meals.

12. A client was admitted to the hospital with iron deficiency anemia and blood-streaked emesis. Which question is **most** appropriate for the nurse to ask in determining the extent of the client's activity intolerance?

- ☐ 1. "What daily activities were you able to do 6 months ago compared with the present?"
- ☐ 2. "How long have you had this problem?"
- ☐ 3. "Have you been able to keep up with all your usual activities?"
- ☐ 4. "Are you more tired now than you used to be?"

13. A healthcare provider (HCP) prescribes vitamin B₁₂ for a client with pernicious anemia. Which sites are appropriate for the nurse to administer vitamin B₁₂ to an adult? Select all that apply.

- ☐ 1. median cutaneous
- ☐ 2. greater femur trochanter
- ☐ 3. acromion muscle
- ☐ 4. ventrogluteal
- ☐ 5. upper back

☐ 6. dorsogluteal

14. Which position would **most** help to decrease a client's discomfort when the client's spouse injects vitamin B₁₂ using the ventrogluteal site?

- ☐ 1. lying on the side with legs extended
- ☐ 2. lying on the abdomen with toes pointed inward
- ☐ 3. leaning over the edge of a low table with hips flexed
- ☐ 4. standing upright with the feet one shoulder-width apart

15. A client is admitted from the emergency department after falling down a flight of stairs at home. The client's vital signs are stable, and the history states that the client had a gastric stapling 2 years ago. The client jokes about being clumsy lately and tripping over things. The nurse should gather additional information by asking the client which questions? Select all that apply.

- ☐ 1. "Are you experiencing numbness in your extremities?"
- ☐ 2. "How much vitamin B₁₂ are you getting?"
- ☐ 3. "Are you feeling depressed?"
- ☐ 4. "Do you feel safe at home?"
- ☐ 5. "Are you getting sufficient iron in your diet?"

16. A client has fatigue, temperature of 99.5°F (37.5°C), dark bronze skin, and dark urine. Hemoglobin is 9 g/dL (90 g/L); hematocrit is 49 (0.49), and red blood cells are 2.75 million/ μ L (2.75×10^{12} /L). What should the nurse do **first**?

- ☐ 1. Initiate an intake and output record.
- ☐ 2. Place the client on bed rest.
- ☐ 3. Place the client on contact isolation.
- ☐ 4. Keep the client out of sunlight.

17. When a client is receiving a cephalosporin, the nurse must monitor the client for which finding?

- ☐ 1. drug-induced hemolytic anemia
- ☐ 2. purpura
- ☐ 3. infectious emboli

- ☐ 4. ecchymosis

18. A client is to have a Schilling's test. The nurse should:

- ☐ 1. administer methylcellulose.
- ☐ 2. start a 24- to 48-hour urine specimen collection.
- ☐ 3. maintain nothing-by-mouth (NPO) status.
- ☐ 4. start a 72-hour stool specimen collection.

19. A client with pernicious anemia is receiving vitamin B₁₂. The nurse should evaluate the client for which expected outcomes of vitamin B₁₂?

- ☐ 1. increased energy
- ☐ 2. healed tongue and lips
- ☐ 3. absence of paresthesias
- ☐ 4. improved clotting time

20. A client with pernicious anemia asks why it is necessary to take vitamin B₁₂ injections forever. Which is the nurse's **best** response?

- ☐ 1. "The reason for your vitamin deficiency is an inability to absorb the vitamin because the stomach is not producing sufficient acid."
- ☐ 2. "The reason for your vitamin deficiency is an inability to absorb the vitamin because the stomach is not producing sufficient amounts of a factor that allows the vitamin to be absorbed."
- ☐ 3. "The reason for your vitamin deficiency is an excessive excretion of the vitamin because of kidney dysfunction."
- ☐ 4. "The reason for your vitamin deficiency is an increased requirement for the vitamin because of rapid red blood cell production."

21. The nurse is assessing a client's activity tolerance. Which report from a treadmill test indicates an abnormal response?

- ☐ 1. pulse rate increased by 20 bpm immediately after the activity
- ☐ 2. respiratory rate decreased by 5 breaths/min
- ☐ 3. diastolic blood pressure increased by 7 mm Hg
- ☐ 4. pulse rate within 6 bpm of resting pulse after 3 minutes of rest

22. In a postoperative client, the hematocrit decreased from 36% (0.36) to 34% (0.34) on the 3rd day even though the red blood cell (RBC) count and

hemoglobin value remained stable at 4.5 million/ μL ($4.5 \times 10^{12}/\text{L}$) and 11.9 g/dL (119 g/L), respectively. The nurse should **next**:

- ☐ 1. check the dressing and drains for frank bleeding.
- ☐ 2. call the healthcare provider (HCP).
- ☐ 3. continue to monitor vital signs.
- ☐ 4. start oxygen at 2 L/min per nasal cannula.

23. The nurse is administering packed red blood cells (PRBCs) to a client. The nurse should **first**:

- ☐ 1. discontinue the IV catheter if a blood transfusion reaction occurs.
- ☐ 2. administer the PRBCs through a percutaneously inserted central catheter line with a 20-gauge needle.
- ☐ 3. flush PRBCs with 5% dextrose and 0.45% normal saline solution.
- ☐ 4. stay with the client during the first 15 minutes of infusion.

24. What directions should the nurse provide to a young female adult with sickle cell anemia? Select all that apply.

- ☐ 1. Drink plenty of fluids when outside in hot weather.
- ☐ 2. Avoid being in high altitudes where less oxygen is available.
- ☐ 3. Be aware that since she is homozygous for HbS, she carries the sickle cell trait.
- ☐ 4. Know that pregnancy with sickle cell disease increases the risk of a crisis.
- ☐ 5. Avoid flying on commercial airlines.

25. The nurse is teaching a client and his family about the client's new diagnosis of hemochromatosis. Which information should the nurse include in the teaching plan?

- ☐ 1. Hemochromatosis is an autoimmune disorder that affects the *HFE* gene.
- ☐ 2. Individuals who are heterozygous for hemochromatosis rarely develop the disease.
- ☐ 3. Individuals who are homozygous for hemochromatosis are carriers of - hemochromatosis.
- ☐ 4. Men are at greater risk for hemochromatosis.

26. A client is having a blood transfusion reaction. What must the nurse do in order of priority from first to last? All options must be used.

1. Notify the healthcare provider (HCP) and blood bank.

2. Complete the appropriate Transfusion Reaction Form(s).

3. Stop the transfusion.

4. Keep the IV open with normal saline infusion.

27. Which safety measures would be **most** important to implement when caring for a client who is receiving 2 units of packed red blood cells (PRBCs)? Select all that apply.

- ☐ 1. Verify that the ABO and Rh of the two units are the same.
- ☐ 2. Infuse a unit of PRBCs in <4 hours.
- ☐ 3. Stop the transfusion if a reaction occurs, but keep the line open.
- ☐ 4. Take vital signs every 15 minutes while the unit is transfusing.
- ☐ 5. Inspect the blood bag for leaks, abnormal color, and clots.
- ☐ 6. Use a 22-gauge catheter for optimal flow of a blood transfusion.

28. A client who had received 25 mL of packed red blood cells (PRBCs) has low back pain and pruritus. After stopping the infusion, the nurse should take what action **next**?

- ☐ 1. Administer prescribed antihistamine and an antipyretic.

- ☐ 2. Collect blood and urine samples and send to the lab.
- ☐ 3. Administer prescribed diuretics.
- ☐ 4. Administer prescribed vasopressors.

29. A client is to receive epoetin injections. What laboratory value should the nurse assess before giving the injection?

- ☐ 1. hematocrit
- ☐ 2. partial thromboplastin time
- ☐ 3. hemoglobin concentration
- ☐ 4. prothrombin time

30. When beginning IV erythropoietin therapy, what actions should the nurse take? Select all that apply.

- ☐ 1. Check the hemoglobin levels before administering subsequent doses.
- ☐ 2. Shake the vial thoroughly to mix the concentrated white, milky solution.
- ☐ 3. Keep the multidose vial refrigerated between scheduled twice-a-day doses.
- ☐ 4. Administer the medication through the IV line without other medications.
- ☐ 5. Adjust the initial doses according to the client's changes in blood pressure.
- ☐ 6. Instruct the client to avoid driving and performing hazardous activity during the initial treatment.

31. A client is afraid of receiving vitamin B₁₂ injections because of potential toxic reactions. Which is the nurse's **best** response to relieve these fears?

- ☐ 1. "Vitamin B₁₂ will cause ringing in the ears before a toxic level is reached."
- ☐ 2. "Vitamin B₁₂ may cause a very mild rash initially."
- ☐ 3. "Vitamin B₁₂ cause mild nausea but nothing toxic."
- ☐ 4. "Vitamin B₁₂ is generally free of toxicity because it is water soluble."

32. A client with iron deficiency anemia is having trouble selecting food

from the hospital menu. Which foods should the nurse suggest to meet the client's need for iron? Select all that apply.

- ☐ 1. eggs
- ☐ 2. brown rice
- ☐ 3. dark green vegetables
- ☐ 4. tea
- ☐ 5. oatmeal

33. A client with macrocytic anemia has a burn on the foot and reports watching television while lying on a heating pad. Which action should be the nurse's **first** response?

- ☐ 1. Assess for potential abuse.
- ☐ 2. Check for diminished sensations.
- ☐ 3. Document the findings.
- ☐ 4. Clean and dress the area.

34. Which is a late symptom of polycythemia vera?

- ☐ 1. headache
- ☐ 2. dizziness
- ☐ 3. pruritus
- ☐ 4. shortness of breath

35. When a client is diagnosed with aplastic anemia, the nurse should assess the client for changes in which physiologic functions?

- ☐ 1. bleeding tendencies
- ☐ 2. intake and output
- ☐ 3. peripheral sensation
- ☐ 4. bowel function

The Client with Platelet Disorders

36. A healthcare provider (HCP) prescribes 0.5 mg of protamine sulfate for a client who is showing signs of bleeding after receiving a 100-unit dose of heparin. The nurse should expect the effects of the protamine sulfate to be noted in how many minutes?

- ☐ 1. 5 minutes
- ☐ 2. 10 minutes
- ☐ 3. 20 minutes
- ☐ 4. 30 minutes

37. The nurse is to administer subcutaneous heparin to an underweight older adult. What facts should the nurse keep in mind when administering this medication? Select all that apply.

- ☐ 1. Administer in the anterior area of the iliac crest.
- ☐ 2. The onset is immediate.
- ☐ 3. Use a 27-G, 5/8-inch (1.6-mm) needle.
- ☐ 4. Cephalosporin potentiates the effects of heparin.
- ☐ 5. Verify the dose with another nurse according to agency policy.

38. The nurse should instruct the client with a platelet count of $31,000/\mu\text{L}$ ($31 \times 10^9/\text{L}$) to:

- ☐ 1. pad sharp surfaces to avoid minor trauma when walking.
- ☐ 2. assess for spontaneous petechiae in the extremities.
- ☐ 3. wear a mask when in crowds of people.
- ☐ 4. check for blood in the urine.

39. A 25-year-old woman with a history of systemic lupus erythematosus was admitted with a severe viral respiratory tract infection and diffuse petechiae. Based on these data, it is **most** important that the nurse further evaluate the client's recent:

- ☐ 1. quality and quantity of food intake.
- ☐ 2. type and amount of fluid intake.
- ☐ 3. extent of weakness and fatigue.
- ☐ 4. length and amount of menstrual flow.

40. When a client with thrombocytopenia has a severe headache, what does the nurse interpret that this may indicate?

- ☐ 1. stress of the disease
- ☐ 2. cerebral bleeding
- ☐ 3. migraine headache

- ☐ 4. sinus congestion

41. The nurse evaluates that the client correctly understands how to report signs and symptoms of bleeding when the client says:

- ☐ 1. "Petechiae are large, red skin bruises."
- ☐ 2. "Ecchymoses are large, purple skin bruises."
- ☐ 3. "Purpura is an open cut on the skin."
- ☐ 4. "Abrasions are small pinpoint red dots on the skin."

42. The nurse should instruct the client with a platelet count of $<150,000/\mu\text{L}$ ($150 \times 10^9/\text{L}$) to avoid which activity?

- ☐ 1. walking for more than 10 minutes
- ☐ 2. straining to have a bowel movement
- ☐ 3. visiting with young children
- ☐ 4. sitting in semi-Fowler's position

43. A client who is taking acetylsalicylic acid (ASA) caplets develops prolonged bleeding from a superficial skin injury on the forearm. The nurse should tell the client to do which action **first**?

- ☐ 1. Place the forearm under a running stream of lukewarm water.
- ☐ 2. Pat the injury with a dry washcloth.
- ☐ 3. Wrap the entire forearm from the wrist to the elbow.
- ☐ 4. Apply an ice pack for 20 minutes.

44. A client's bone marrow report reveals normal stem cells and precursors of platelets (megakaryocytes) in the presence of decreased circulating platelets. The nurse recognizes a knowledge deficit when the client says:

- ☐ 1. "I need to stop flossing and throw away my hard toothbrush."
- ☐ 2. "I am glad that my report turned out normal."
- ☐ 3. "Now I know why I have all these bruises."
- ☐ 4. "I should not jump off that last step anymore."

45. A client with thrombocytopenia has developed a hemorrhage. The nurse should assess the client for which finding?

- ☐ 1. tachycardia

- ☐ 2. bradycardia
- ☐ 3. decreased Paco_2
- ☐ 4. narrowed pulse pressure

46. The client with idiopathic thrombocytopenic purpura (ITP) asks the nurse why it is necessary to take steroids. The nurse should base the response on which information?

- ☐ 1. Steroids destroy the antibodies and prolong the life of platelets.
- ☐ 2. Steroids neutralize the antigens and prolong the life of platelets.
- ☐ 3. Steroids increase phagocytosis and increase the life of platelets.
- ☐ 4. Steroids alter the spleen's recognition of platelets and increase the life of platelets.

47. A client is to be discharged on prednisone. Which statement indicates that the client understands important concepts about the medication therapy?

- ☐ 1. "I need to take the medicine in divided doses at morning and bedtime."
- ☐ 2. "I am to take 40 mg of prednisone for 2 months and then stop."
- ☐ 3. "I need to wear or carry identification that I am taking prednisone."
- ☐ 4. "Prednisone will give me extra protection from colds and flu."

48. When teaching the client older than age 50 who is receiving long-term prednisone therapy, what should the nurse suggest to the client?

- ☐ 1. Take the prednisone with food.
- ☐ 2. Take over-the-counter antiemetics.
- ☐ 3. Exercise three to four times a week.
- ☐ 4. Eat foods that are low in potassium.

49. The nurse is preparing a teaching plan about increased exercise for a female client who is receiving long-term corticosteroid therapy. What type of exercise is **most** appropriate for this client?

- ☐ 1. floor exercises
- ☐ 2. stretching
- ☐ 3. running
- ☐ 4. walking

50. The nurse is teaching a female client with a history of acquired

thrombocytopenia about how to prevent and control hemorrhage. Which statement indicates that the client needs further instruction?

- ☐ 1. "I can apply direct pressure over small cuts for at least 5 to 10 minutes to stop a venous bleed."
- ☐ 2. "I can count the number of tissues saturated to detect blood loss during a nosebleed."
- ☐ 3. "I can take hormones to decrease blood loss during menses."
- ☐ 4. "I can count the number of sanitary napkins to detect excess blood loss during menses."

51. A client has been on long-term prednisone therapy. What should the nurse instruct the client to include in her diet? Select all that apply.

- ☐ 1. carbohydrates
- ☐ 2. protein
- ☐ 3. trans fat
- ☐ 4. potassium
- ☐ 5. calcium
- ☐ 6. vitamin D

52. Platelets should **not** be administered when:

- ☐ 1. the platelet bag is cold.
- ☐ 2. the platelets are 2 days old.
- ☐ 3. the platelet bag is at room temperature.
- ☐ 4. the platelets are 12 hours old.

53. The nurse is preparing to administer platelets. The nurse should:

- ☐ 1. check the ABO compatibility.
- ☐ 2. administer the platelets slowly.
- ☐ 3. gently rotate the bag.
- ☐ 4. use a whole-blood tubing set.

54. Which indicates that a client has achieved the goal of correctly demonstrating deep breathing for an upcoming splenectomy? The client:

- ☐ 1. breathes in through the nose and out through the mouth.
- ☐ 2. breathes in through the mouth and out through the nose.

- ☐ 3. uses diaphragmatic breathing in the lying, sitting, and standing positions.
- ☐ 4. takes a deep breath in through the nose, holds it for 5 seconds, and blows out through pursed lips.

55. A client is scheduled for an elective splenectomy. The **last** thing the nurse should do before the client goes to surgery is to determine that the client has:

- ☐ 1. voided completely.
- ☐ 2. signed the consent.
- ☐ 3. vital signs recorded.
- ☐ 4. name band on wrist.

56. When receiving a client from the postanesthesia care unit after a splenectomy, which should the nurse assess **next** after obtaining vital signs?

- ☐ 1. nasogastric drainage
- ☐ 2. urinary catheter
- ☐ 3. dressing
- ☐ 4. need for pain medication

57. A client who had a splenectomy yesterday has a nasogastric (NG) tube. The expected outcome of using the NG tube is to:

- ☐ 1. move the stomach away from where the spleen was removed.
- ☐ 2. irrigate the operative site.
- ☐ 3. decrease abdominal distention.
- ☐ 4. assess for the gastric pH as peristalsis returns.

58. A client who had a splenectomy is being discharged. The nurse should instruct the client to:

- ☐ 1. not drive a car for 6 weeks.
- ☐ 2. alternate rest and activity.
- ☐ 3. make an appointment for the staples to be removed.
- ☐ 4. report early signs of infection.

59. The nurse should assess a client at risk for acute disseminated intravascular coagulation (DIC) for which early sign?

- ☐ 1. severe shortness of breath
- ☐ 2. bleeding without history or cause
- ☐ 3. orthopnea
- ☐ 4. hematuria

60. Which is contraindicated for a client diagnosed with disseminated intravascular coagulation (DIC)?

- ☐ 1. treating the underlying cause
- ☐ 2. administering heparin
- ☐ 3. administering warfarin sodium
- ☐ 4. replacing depleted blood products

61. A client with disseminated intravascular coagulation develops clinical manifestations of microvascular thrombosis. The nurse should assess the client for:

- ☐ 1. hemoptysis.
- ☐ 2. focal ischemia.
- ☐ 3. petechiae.
- ☐ 4. hematuria.

62. Which is a finding associated with internal bleeding with disseminated intravascular coagulation?

- ☐ 1. bradycardia
- ☐ 2. hypertension
- ☐ 3. increasing abdominal girth
- ☐ 4. petechiae

The Client with White Blood Cell Disorders

63. A young adult is diagnosed with infectious mononucleosis. The white blood cell (WBC) count is 19,000/ μ L (19×10^9 /L). The client has a streptococcal throat infection, enlarged spleen, and aching muscles. Which instructions should the nurse include in discharge planning with the client? Select all that apply.

- ☐ 1. Stay on bed rest until the temperature is normal.

- ☐ 2. Gargle with warm saline while the throat is irritated.
- ☐ 3. Increase intake of fluids until the infection subsides.
- ☐ 4. Wear a mask if others are present.
- ☐ 5. Avoid contact sports while the spleen is enlarged.

64. The daily white blood cell (WBC) count in a client with aplastic anemia drops overnight from 3,900 to 2,900/ μL (3.9 to $2.9 \times 10^9/\text{L}$). Which is the appropriate nursing intervention?

- ☐ 1. Continue monitoring the client.
- ☐ 2. Call the laboratory to verify the report.
- ☐ 3. Document the finding.
- ☐ 4. Call the healthcare provider (HCP), and request that the client be placed in reverse isolation.

65. A client who had an exploratory laparotomy 3 days ago has a white blood cell (WBC) differential with a shift to the left. The nurse instructs unlicensed assistive personnel (UAP) to report which clinical manifestation of this laboratory report?

- ☐ 1. swelling around the incision
- ☐ 2. redness around the incision
- ☐ 3. elevated temperature
- ☐ 4. purulent wound drainage

66. The nurse is developing a care plan with a client who has leukemia. What instructions should the nurse include in the plan? Select all that apply.

- ☐ 1. Monitor temperature and report elevation.
- ☐ 2. Recognize signs and symptoms of infection.
- ☐ 3. Avoid crowds.
- ☐ 4. Maintain integrity of skin and mucous membranes.
- ☐ 5. Take a baby aspirin each day.

67. A client with neutropenia has an absolute neutrophil count (ANC) of 900 ($0.9 \times 10^9/\text{L}$). What is the client's risk of infection?

- ☐ 1. normal risk
- ☐ 2. moderate risk

- ☐ 3. high risk
- ☐ 4. extremely high risk

68. Which nursing action is **most** important in preventing cross-contamination?

- ☐ 1. changing gloves immediately after use
- ☐ 2. standing 2 feet (61 cm) from the client
- ☐ 3. speaking minimally when in the room
- ☐ 4. wearing protective coverings

69. What should the nurse teach the client with neutropenia and the family to avoid?

- ☐ 1. using suppositories or enemas
- ☐ 2. using a high-efficiency particulate air (HEPA) filter mask
- ☐ 3. performing perianal care after every bowel movement
- ☐ 4. performing oral care after every meal

70. A client with granulocytopenia has many visitors. The **most** important measure to prevent infection is for the visitors to:

- ☐ 1. visit only if they do not have a cold.
- ☐ 2. wash their hands.
- ☐ 3. leave the children at home.
- ☐ 4. not to kiss the client.

71. A nurse is obtaining consent for a bone marrow aspiration. Which actions should the nurse take? Select all that apply.

- ☐ 1. Witness the client signing the consent form.
- ☐ 2. Evaluate that the client understands the procedure.
- ☐ 3. Explain the risks of the procedure to the client.
- ☐ 4. Verify that the client is signing the consent form of his or her own free will.
- ☐ 5. Determine that the client understands postprocedure care.

72. A client is about to undergo bone marrow aspiration of the sternum. What should the nurse tell the client?

- ☐ 1. "You may feel a solution being wiped over your entire front from your

neck down to your navel and out to your shoulders.”

- ☐ 2. “You will not feel the local anesthetic being applied because it will be sprayed on.”
- ☐ 3. “You will feel a pulling type of discomfort for a few seconds.”
- ☐ 4. “After the needle is removed, you will feel a bandage being applied around your chest.”

73. Twenty-four hours after a bone marrow aspiration, the nurse evaluates which client outcome as an appropriate one?

- ☐ 1. The client maintains bed rest.
- ☐ 2. There is redness and swelling at the aspiration site.
- ☐ 3. The client requests a strong analgesic for pain.
- ☐ 4. There is no bleeding at the aspiration site.

74. A client states, “I do not want any more tests. Who cares what kind of leukemia I have? I just want to be treated now.” Which is the nurse’s **best** response?

- ☐ 1. “I am sure you are frustrated and want to be well now.”
- ☐ 2. “Your treatment can be more effective if it is based on more specific information about your disease.”
- ☐ 3. “Now, you know the tests are necessary and that you are just upset right now.”
- ☐ 4. “I understand how you feel.”

75. During the induction stage for treatment of leukemia, the nurse should remove which items that the family has brought into the room?

- ☐ 1. a prayer book
- ☐ 2. a picture
- ☐ 3. a bouquet of flowers
- ☐ 4. a hairbrush

76. The nurse understands that the client who is undergoing induction therapy for leukemia needs additional instruction when the client makes which statement?

- ☐ 1. “I will pace my activities with rest periods.”
- ☐ 2. “I cannot wait to get home to my cat!”

- ☐ 3. "I will use warm saline gargle instead of brushing my teeth."
- ☐ 4. "I must report a temperature of 100°F (37.7°C)."

77. A client with chronic myelogenous leukemia is taking imatinib. The nurse should instruct the client to report which adverse effect of this drug?

- ☐ 1. edema
- ☐ 2. numbness and tingling in extremities
- ☐ 3. bloody stools
- ☐ 4. persistent cough

78. A client with acute lymphocytic leukemia is receiving vincristine. Prior to infusing the drug, the nurse administers diphenhydramine. The nurse should inform the client that the expected outcome of using diphenhydramine in this situation is to:

- ☐ 1. promote sleep, while the vincristine is infusing.
- ☐ 2. decrease incidence of a reaction to the vincristine.
- ☐ 3. potentiate the action of the vincristine.
- ☐ 4. reduce anxiety associated with the vincristine infusion.

79. A female client is receiving chemotherapy and is experiencing pancytopenia. Which laboratory result **most** warrants that the nurse immediately contact the healthcare provider (HCP)?

- ☐ 1. platelet count of 12,000/mm³
- ☐ 2. WBC count of 4,000/mm³
- ☐ 3. absolute neutrophil count of 1,500/mm³
- ☐ 4. hemoglobin of 12 g/100 mL

80. A nurse is administering an IV antineoplastic agent when the client says, "My arm is burning by the IV site." What should the nurse do **first**?

- ☐ 1. Slow the infusion rate and check the IV site.
- ☐ 2. Call the healthcare provider (HCP) to report the incident.
- ☐ 3. Stop infusing the medication.
- ☐ 4. Place a warm, moist pack on the IV site area.

81. A client who is receiving a blood transfusion suddenly experiences chills and a temperature of 101°F (38°C). The client also has a headache and

appears flushed. In what order, from first to last, should the nurse perform the actions? All options must be used.

1. Obtain a blood culture from the client.

2. Send the blood bag and administration set to the blood bank.

3. Stop the blood infusion.

4. Infuse normal saline to keep the vein open.

82. A client undergoing antineoplastic therapy is prescribed subcutaneous epoetin. The nurse evaluates that the drug is effective when:

- ☐ 1. biopsies no longer show malignancy.
- ☐ 2. hemoglobin levels rise.
- ☐ 3. nausea and vomiting stop.
- ☐ 4. a scan shows tumor shrinkage.

83. The goal of nursing care for a client with acute myeloid leukemia (AML) is to prevent:

- ☐ 1. cardiac arrhythmias.
- ☐ 2. liver failure.
- ☐ 3. renal failure.
- ☐ 4. hemorrhage.

84. At what age is an individual **most** at risk for acquiring acute

lymphocytic leukemia (ALL)?

- ☐ 1. 4 to 12 years
- ☐ 2. 20 to 30 years
- ☐ 3. 40 to 50 years
- ☐ 4. 60 to 70 years

85. The client with acute lymphocytic leukemia (ALL) is at risk for infection. What action should the nurse take?

- ☐ 1. Place the client in a private room.
- ☐ 2. Have the client wear a mask.
- ☐ 3. Have staff wear gowns and gloves.
- ☐ 4. Restrict visitors.

86. The nurse is planning care with a client with acute leukemia who has mucositis. The nurse should advise the client that after every meal and every 4 hours while awake, the client should use:

- ☐ 1. lemon-glycerin swabs.
- ☐ 2. a commercial mouthwash.
- ☐ 3. saline.
- ☐ 4. a commercial toothpaste and brush.

87. The client with acute leukemia and the healthcare team establish mutual client outcomes of improved tidal volume and activity tolerance. Which measure would be **least** likely to promote these outcomes?

- ☐ 1. ambulating in the hallway
- ☐ 2. sitting up in a chair
- ☐ 3. lying in bed and taking deep breaths
- ☐ 4. using a stationary bicycle in the room

88. The nurse is evaluating the client's understanding about combination chemotherapy. Which statement by the client about reasons for using combination chemotherapy indicates the need for **further** explanation?

- ☐ 1. "Combination chemotherapy is used to interrupt cell growth cycle at different points."
- ☐ 2. "Combination chemotherapy is used to destroy cancer cells and treat

side effects simultaneously.”

- ☐ 3. “Combination chemotherapy is used to decrease resistance.”
- ☐ 4. “Combination chemotherapy is used to minimize the toxicity from using high doses of a single agent.”

89. In providing care to the client with leukemia who has developed thrombocytopenia, the nurse assesses the most common sites for bleeding. Which is **not** a common site?

- ☐ 1. biliary system
- ☐ 2. gastrointestinal tract
- ☐ 3. brain and meninges
- ☐ 4. pulmonary system

90. The nurse’s **best** explanation for why the severely neutropenic client is placed in reverse isolation is that reverse isolation helps prevent the spread of organisms:

- ☐ 1. to the client from sources outside the client’s environment.
- ☐ 2. from the client to healthcare personnel, visitors, and other clients.
- ☐ 3. by using special techniques to dispose of contaminated materials.
- ☐ 4. by using special techniques to handle the client’s linens and personal items.

The Client with Lymphoma

91. Which clinical manifestation does the nurse **most** likely observe in a client with Hodgkin’s disease?

- ☐ 1. difficulty swallowing
- ☐ 2. painless, enlarged cervical lymph nodes
- ☐ 3. difficulty breathing
- ☐ 4. a feeling of fullness over the liver

92. The nurse is developing a care plan for a client who has had radiation therapy for Hodgkin’s lymphoma. What is the primary goal of care for this client?

- ☐ 1. Maintain fluid balance.
- ☐ 2. Obtain sufficient exercise.

- ☐ 3. Prevent infection.
- ☐ 4. Avoid depression.

93. A client with a suspected diagnosis of Hodgkin's disease is to have a lymph node biopsy. What should the nurse make sure that personnel involved with the procedure do?

- ☐ 1. Maintain sterile technique.
- ☐ 2. Use a mask, gloves, and a gown when assisting with the procedure.
- ☐ 3. Send the specimen to the laboratory when someone is available to take it.
- ☐ 4. Ensure that all instruments used are placed in a sealed and labeled container.

94. The client with Hodgkin's disease undergoes an excisional cervical lymph node biopsy under local anesthesia. After the procedure, what does the nurse assess **first**?

- ☐ 1. vital signs
- ☐ 2. the incision
- ☐ 3. the airway
- ☐ 4. neurologic signs

95. When assessing the client with Hodgkin's disease, the nurse should observe the client for which finding?

- ☐ 1. herpes zoster infections
- ☐ 2. discolored teeth
- ☐ 3. hemorrhage
- ☐ 4. hypercellular immunity

96. The client with Hodgkin's disease develops B symptoms. What do these manifestations indicate?

- ☐ 1. The client has a low-grade fever (temperature lower than 100°F [37.8°C]).
- ☐ 2. The client has a weight loss of 5% or less of body weight.
- ☐ 3. The client has night sweats.
- ☐ 4. The client probably has not progressed to an advanced stage.

97. The nurse is developing a discharge plan with a client who has lymphoma. What should the nurse emphasize to the client?

- ☐ 1. Use analgesics as needed.
- ☐ 2. Take a shower with perfumed shower gel.
- ☐ 3. Wear a mask when outside of the home.
- ☐ 4. Take an antipyretic every morning.

98. The client asks the nurse to explain what it means that Hodgkin's disease is diagnosed at stage 1A. What describes the involvement of the disease?

- ☐ 1. involvement of a single lymph node
- ☐ 2. involvement of two or more lymph nodes on the same side of the diaphragm
- ☐ 3. involvement of lymph node regions on both sides of the diaphragm
- ☐ 4. diffuse disease of one or more extralymphatic organs

99. A client is undergoing a bone marrow aspiration and biopsy. What is the **best** way for the nurse to help the client and two upset family members handle anxiety during the procedure?

- ☐ 1. Allow the client's family to stay as long as possible.
- ☐ 2. Stay with the client without speaking.
- ☐ 3. Encourage the client to take slow, deep breaths to relax.
- ☐ 4. Allow the client time to express feelings.

100. The nurse explains to the client with Hodgkin's disease that a bone marrow biopsy will be taken after the aspiration. What should the nurse explain about the biopsy?

- ☐ 1. "Your biopsy will be performed before the aspiration because enough tissue may be obtained so that you will not have to go through the aspiration."
- ☐ 2. "You will feel a pressure sensation when the biopsy is taken but should not feel actual pain; if you do, tell the healthcare provider so that you can be given extra numbing medicine."
- ☐ 3. "You may hear a crunch as the needle passes through the bone, but when the biopsy is taken, you will feel a suction-type pain that will last for

just a moment.”

- ☐ 4. “You will be shaved and cleaned with an antiseptic agent, after which the healthcare provider will inject a needle without making an incision to aspirate out the bone marrow.”

101. A client with advanced Hodgkin’s disease is admitted to hospice because death is imminent. The goal of nursing care at this time is to:

- ☐ 1. reduce the client’s fear of pain.
- ☐ 2. support the client’s wish to discontinue further therapy.
- ☐ 3. prevent feelings of isolation.
- ☐ 4. help the client overcome feelings of social inadequacy.

102. The client is a survivor of non-Hodgkin’s lymphoma. Which statement indicates the client needs additional information?

- ☐ 1. “Regular screening is very important for me.”
- ☐ 2. “The survivor rate is directly proportional to the incidence of second malignancy.”
- ☐ 3. “The survivor rate is indirectly proportional to the incidence of second malignancy.”
- ☐ 4. “It is important for survivors to know the stage of the disease and their current treatment plan.”

The Client Who Is in Shock

103. What is the **most** important goal of nursing care for a client who is in shock?

- ☐ 1. Manage fluid overload.
- ☐ 2. Manage increased cardiac output.
- ☐ 3. Manage inadequate tissue perfusion.
- ☐ 4. Manage vasoconstriction of vascular beds.

104. Which finding indicates hypovolemic shock in an adult who has had a 15% blood loss?

- ☐ 1. pulse rate <60 bpm
- ☐ 2. respiratory rate of 4 breaths/min
- ☐ 3. pupils unequally dilated

- ☐ 4. systolic blood pressure <90 mm Hg

105. Which finding is the **best** indication that fluid replacement for the client in hypovolemic shock is adequate?

- ☐ 1. urine output >30 mL/h
- ☐ 2. systolic blood pressure >110 mm Hg
- ☐ 3. diastolic blood pressure >90 mm Hg
- ☐ 4. respiratory rate of 20 breaths/min

106. Which finding is a risk factor for hypovolemic shock?

- ☐ 1. hemorrhage
- ☐ 2. antigen-antibody reaction
- ☐ 3. gram-negative bacteria
- ☐ 4. vasodilation

107. Which is a **priority** assessment for the client in shock who is receiving an IV infusion of packed red blood cells and normal saline solution?

- ☐ 1. fluid balance
- ☐ 2. anaphylactic reaction
- ☐ 3. pain
- ☐ 4. altered level of consciousness

108. The client who does not respond adequately to fluid replacement has a prescription for an IV infusion of dopamine hydrochloride at 5 mcg/kg/min. To determine that the drug is having the desired effect, the nurse should assess the client for:

- ☐ 1. increased renal and mesenteric blood flow.
- ☐ 2. increased cardiac output.
- ☐ 3. vasoconstriction.
- ☐ 4. reduced preload and afterload.

109. A client is receiving dopamine hydrochloride for treatment of shock. What action should the nurse take?

- ☐ 1. Administer pain medication concurrently.
- ☐ 2. Monitor blood pressure continuously.

- ☐ 3. Evaluate arterial blood gases at least every 2 hours.
- ☐ 4. Monitor for signs of infection.

110. A client who has been taking warfarin has been admitted with severe acute rectal bleeding and the following laboratory results: international normalized ratio (INR), 8; hemoglobin, 11 g/dL (110 g/L); and hematocrit, 33% (0.33). In which order, from first to last, should the nurse implement the healthcare provider's prescriptions? All options must be used.

1. Give 1 unit fresh frozen plasma (FFP).

2. Administer vitamin K 2.5 mg by mouth.

3. Schedule the client for sigmoidoscopy.

4. Administer IV dextrose 5% in 0.45% normal saline.

111. When assessing a client for early septic shock, the nurse should assess the client for which finding?

- ☐ 1. cool, clammy skin
- ☐ 2. warm, flushed skin
- ☐ 3. increased blood pressure
- ☐ 4. hemorrhage

112. A client with toxic shock has been receiving ceftriaxone sodium, 1 g every 12 hours. In addition to culture and sensitivity studies, what other

laboratory finding should the nurse monitor?

- ☐ 1. serum creatinine
- ☐ 2. spinal fluid analysis
- ☐ 3. arterial blood gases
- ☐ 4. serum osmolality

113. Which nursing intervention is **most** important in preventing septic shock?

- ☐ 1. administering IV fluid replacement therapy as prescribed
- ☐ 2. obtaining vital signs every 4 hours for all clients
- ☐ 3. monitoring red blood cell counts for elevation
- ☐ 4. maintaining asepsis of indwelling urinary catheters

114. Which finding is an indication of a complication of septic shock?

- ☐ 1. anaphylaxis
- ☐ 2. acute respiratory distress syndrome (ARDS)
- ☐ 3. chronic obstructive pulmonary disease (COPD)
- ☐ 4. mitral valve prolapse

Managing Care, Quality, and Safety for Clients with Hematologic Health Problems

115. A nurse is taking care of two clients who have a prescription to receive a blood transfusion of packed red blood cells at the same time. The first client's blood pressure dropped from the preoperative value of 120/80 mm Hg to a postoperative value of 100/50 mm Hg. The second client is hospitalized because he developed dehydration and anemia following pneumonia. After checking the patency of their IV lines and vital signs, what should the nurse do **next**?

- ☐ 1. Call for both clients' blood transfusions at the same time.
- ☐ 2. Ask another nurse to verify the compatibility of both units at the same time.
- ☐ 3. Call for and hang the first client's blood transfusion.
- ☐ 4. Ask another nurse to call for and hang the blood for the second client.

116. When a blood transfusion is terminated following a reaction, what actions must the nurse take? Select all that apply.

- ☐ 1. Send freshly collected urine samples to the laboratory.
- ☐ 2. Return the remainder of the blood component unit to the blood bank.
- ☐ 3. Return the intravenous administration set to the blood bank.
- ☐ 4. Alert Risk Management about the incident.
- ☐ 5. Report the incident to the Infection Control Manager.

117. The nurse is administering a medication to a client with myeloid leukemia and does not know the use, dose, or side effects. To obtain the **most** up-to-date information about this drug, what should the nurse do?

- ☐ 1. Check a commercially published drug guide.
- ☐ 2. Read a pharmacology textbook.
- ☐ 3. Consult the drug guide provided by the clinical agency.
- ☐ 4. Review information at the drug manufacturer's website.

118. The charge nurse on a hematology/oncology unit is reviewing the policy for using abbreviations with the staff. The charge nurse should emphasize which information about why dangerous abbreviations need to be eliminated? Select all that apply.

- ☐ 1. to ensure efficient and accurate communication
- ☐ 2. to prevent medication errors
- ☐ 3. to ensure client safety
- ☐ 4. to make it easier for clients to understand the medication prescriptions
- ☐ 5. to make data entry into a computerized health record easier

119. The nurse should remind the unlicensed assistive personnel (UAP) that the **most** important goal in the care of the neutropenic client in isolation is:

- ☐ 1. listening to the client's feelings of concern.
- ☐ 2. completing the client's care in a calm manner.
- ☐ 3. completing all of the client's care at one time.
- ☐ 4. instructing the client to dispose of the tissue used after blowing the nose.

Answers, Rationales, and Test-Taking Strategies

The answers and rationales for each question follow below, along with keys (🔑) to the client need (CN) and cognitive level (CL) for each question. In addition, you will also see a glossary icon (📖) highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 12–23 and pages 35–36 in Part 1 of this book.

The Client with Red Blood Cell Disorders

1. 3,1,2,4. First, the nurse must verify that the client has voluntarily signed a **consent** form before the procedure begins and check that the client understands the procedure. The nurse then positions the client in a side-lying, or *lateral decubitus*, position with the affected side up. Then, the nurse should clean the skin site and surrounding area with an antiseptic solution before the **healthcare provider (HCP)** 📖 numbs the site and collects the specimen. When the procedure is finished, the nurse must apply ice to the biopsy site to reduce pain.

🔑 CN: Management of care; CL: Synthesize

2. 1,2,5. Nausea and vomiting are common adverse effects of oral iron preparations. The nurse should first ask the client why the client does not want to take the oral medication and then suggest ways to decrease the nausea and vomiting. Ginger may help minimize the nausea, and the client can try this remedy and evaluate its effectiveness. Iron should be taken on an empty stomach but can be taken with orange juice. The client can evaluate if this helps the nausea. Stool softeners should not be used in clients with iron deficiency anemia. Instead, constipation can be prevented by following a high-fiber diet. Administering iron intramuscularly is done only if other approaches are not effective.

🔑 CN: Health promotion and maintenance; CL: Synthesize

3. 1. This client is likely experiencing fatigue and should increase her periods of rest. The fatigue may be caused by anemia from depletion of red blood cells due to the chemotherapy. Asking the client to limit her activities may cause the client to become withdrawn. The information given does not support limiting activity. Increasing fluid intake will not reduce the fatigue. The information does not indicate that the client is immunosuppressed and should avoid contact with others.

CN: Physiological adaptation; CL: Synthesize

4. 1,2,3. Using designated donors does not decrease the risk of contracting infectious diseases, such as the Epstein-Barr virus, HIV, or CMV. Hepatitis A is transmitted by the oral-fecal route, not the blood route; however, hepatitis B and C can be contracted from a designated donor. Malaria is transmitted by mosquitoes.

CN: Safety and infection control; CL: Apply

5. 1. For the client with iron deficiency anemia, a rich source of iron is needed in the diet, and eggs are high in iron. Other foods high in iron include organ and muscle (dark) meats; shellfish, shrimp, and tuna; enriched, whole-grain, and fortified cereals and breads; legumes, nuts, dried fruits, and beans; oatmeal; and sweet potatoes. Dark green, leafy vegetables and citrus fruits are good sources of vitamin C. Cheese is a good source of calcium.

CN: Reduction of risk potential; CL: Apply

6. 3. Good sources of vitamin B₁₂ include meats and dairy products. Whole grains are a good source of thiamine. Green, leafy vegetables are good sources of niacin, folate, and carotenoids (precursors of vitamin A). Broccoli and Brussels sprouts are good sources of ascorbic acid (vitamin C).

CN: Reduction of risk potential; CL: Apply

7. 4. Normal range of folic acid is 1.8 to 9 ng/mL (4.1 to 20.4 nmol/L), and normal range of vitamin B₁₂ is 200 to 900 pg/mL (147.6 to 664 pmol/L). A low folic acid level in the presence of a normal vitamin B₁₂ level is indicative of a primary folic acid deficiency anemia. Factors that affect the absorption of folic acid are drugs such as methotrexate, oral contraceptives, antiseizure

drugs, and alcohol. The total bilirubin, serum creatinine, and hemoglobin values are within normal limits.

CN: Physiological adaptation; CL: Analyze

8. 2. The defining characteristic of pernicious anemia, a megaloblastic anemia, is lack of the intrinsic factor, which results from atrophy of the stomach wall. Without the intrinsic factor, vitamin B₁₂ cannot be absorbed in the small intestine, and folic acid needs vitamin B₁₂ for deoxyribonucleic acid synthesis of RBCs. The gastric analysis is done to determine the primary cause of the anemia. An elevated excretion of the injected radioactive vitamin B₁₂, which is protocol for the first and second stages of the Schilling test, indicates that the client has the intrinsic factor and can absorb vitamin B₁₂ in the intestinal tract. A sedimentation rate of 16 mm/h is normal for both men and women and is a nonspecific test to detect the presence of inflammation; it is not specific to anemias. An RBC value within the normal range does not indicate an anemia.

CN: Physiological adaptation; CL: Synthesize

9. 2. Clients with aplastic anemia are severely immunocompromised and at risk for infection and possible death related to bone marrow suppression and pancytopenia. Strict aseptic technique and reverse isolation are important measures to prevent infection. Although diet, reduced stress, and rest are valued in supporting health, the potentially fatal consequence of an acute infection places it as a priority for teaching the client about health maintenance. Animal meat and dark green leafy vegetables, good sources of vitamin B₁₂ and folic acid, should be included in the daily diet. Yoga and meditation are good complementary therapies to reduce stress. Eight hours of rest and naps are good for spacing and pacing activity and rest.

CN: Reduction of risk potential; CL: Synthesize

10. 4. Vitamin B₁₂ combines with intrinsic factor in the stomach and is then carried to the ileum, where it is absorbed into the bloodstream. In this situation, vitamin B₁₂ cannot be absorbed regardless of the amount of oral intake of sources of vitamin B₁₂, such as animal protein or vitamin B₁₂

tablets. Vitamin B₁₂ needs to be injected every month because the ileum has been surgically removed. Warm salt water is used to soothe sore mucous membranes. Crohn's disease and a small-bowel resection may cause several loose stools a day, but the client does not report having this problem.

 CN: Physiological adaptation; CL: Analyze

11. 3. Coffee and tea increase gastrointestinal motility and inhibit the absorption of nonheme iron. Clients are instructed to add dried fruits to dishes at every meal because dried fruits are a nonheme or nonanimal iron source. Cooking in iron cookware, especially acid-based foods such as tomatoes, adds iron to the diet. Clients are instructed to add a rich supply of vitamin C to every meal because the absorption of iron is increased when food with vitamin C or ascorbic acid is consumed.

 CN: Reduction of risk potential; CL: Evaluate

12. 1. It is difficult to determine activity intolerance without objectively comparing activities from one time frame to another. Because iron deficiency anemia can occur gradually and individual endurance varies, the nurse can best assess the client's activity tolerance by asking the client to compare activities 6 months ago and at present. Asking a client how long a problem has existed is a very open-ended question that allows for too much subjectivity for any definition of the client's activity tolerance. Also, the client may not even identify that a "problem" exists. Asking the client whether he is staying abreast of usual activities addresses whether the tasks were completed, not the tolerance of the client while the tasks were being completed or the resulting condition of the client after the tasks were completed. Asking the client if he is more tired now than usual does not address his activity tolerance. Tiredness is a subjective evaluation and again can be distorted by factors such as the gradual onset of the anemia or the endurance of the individual.

 CN: Reduction of risk potential; CL: Analyze

13. 4,6. A client with pernicious anemia has lost the ability to absorb vitamin B₁₂ either because of the lack of an acidic gastric environment or the lack of the intrinsic factor. Vitamin B₁₂ must be administered by a deep

intramuscular route. The ventrogluteal and dorsogluteal locations are the most acceptable sites for a deep intramuscular injection. The other sites are not acceptable.

CN: Pharmacological and parenteral therapies; CL: Apply

14. 2. To promote comfort when injecting at the ventrogluteal site, the position of choice is with the client lying on the abdomen with toes pointed inward. This positioning promotes muscle relaxation, which decreases the discomfort of making an injection into a tense muscle. Lying on the side with legs extended will not provide the greatest muscle relaxation. Leaning over the edge of a table with the hips flexed and standing upright with the feet apart will increase muscular tension.

CN: Physiological adaptation; CL: Apply

15. 1,2,3,4. The nurse should ask the client about symptoms related to pernicious anemia because the client had the stomach stapled 2 years ago and shows no history of supplemental vitamin B₁₂. Numbness and tingling relate to a loss of intrinsic factor from the gastric stapling. Intrinsic factor is necessary for absorption of vitamin B₁₂. The nurse should suspect pernicious anemia if the client is not taking supplemental vitamin B₁₂. Other signs and symptoms of pernicious anemia include cognitive problems and depression. The nurse also should ask about the client's support at home in case the fall was not an accident. Pernicious anemia is not related to dietary intake of iron.

CN: Reduction of risk potential; CL: Analyze

16. 1. The nurse should prepare to start an intake and output record because the client is exhibiting clinical manifestations of anemia with jaundice and is demonstrating a fluid imbalance. The client does not need to be on bed rest at this point. The client is not contagious and does not need to be placed in contact isolation. The changes in the color of the skin and urine are related to the jaundice and will not be affected by sunlight.

CN: Physiological adaptation; CL: Synthesize

17. 1. Drug-induced hemolytic anemia is acquired, antibody-mediated, RBC destruction precipitated by medications, such as cephalosporins, sulfa drugs, rifampin, methyldopa, procainamide, quinidine, and thiazides. Purpura

is a condition with various manifestations characterized by hemorrhages into the skin, mucous membranes, internal organs, and other tissues. Infectious emboli are clumps of bacteria present in blood or lymph. Ecchymoses are skin discolorations due to extravasations of blood into the skin or mucous membranes.

CN: Reduction of risk potential; CL: Analyze

18. 2. Urinary vitamin B₁₂ levels are measured after the ingestion of radioactive vitamin B₁₂. A 24- to 48-hour urine specimen is collected after administration of an oral dose of radioactively tagged vitamin B₁₂ and an injection of nonradioactive vitamin B₁₂. In a healthy state of absorption, excess vitamin B₁₂ is excreted in the urine; in a malabsorptive state or when the intrinsic factor is missing, vitamin B₁₂ is excreted in the feces.

Methylcellulose is a bulk-forming agent. Laxatives interfere with the absorption of vitamin B₁₂. The client is NPO 8 to 12 hours before the test but is not NPO during the test. A stool collection is not a part of the Schilling test. If stool contaminates the urine collection, the results will be altered.

CN: Pharmacological and parenteral therapies; CL: Analyze

19. 3. Pernicious anemia is caused by a lack of vitamin B₁₂. Primary symptoms include neuropathy with paresthesias of hands and feet. The nurse assesses the client to determine the effectiveness of the monthly dose of vitamin B₁₂, which is to reverse the deficiency and the related symptoms. Improved energy is associated with treatment for iron deficiency anemia. Healing of cracked lips and tongue is an outcome of taking folic acid for folic acid deficiency. Delayed clotting time is associated with hemophilia; the clotting time is not affected by vitamin B₁₂.

CN: Pharmacological and parenteral therapies; CL: Evaluate

20. 2. Most clients with pernicious anemia have deficient production of intrinsic factor in the stomach. Intrinsic factor attaches to the vitamin in the stomach and forms a complex that allows the vitamin to be absorbed in the small intestine. The stomach is producing enough acid, there is not an excessive excretion of the vitamin, and there is not a rapid production of red

blood cells in this condition.

CN: Physiological adaptation; CL: Synthesize

21. 2. The normal physiologic response to activity is an increased metabolic rate over the resting basal rate. The decrease in respiratory rate indicates that the client is not strong enough to complete the mechanical cycle of respiration needed for gas exchange. The postactivity pulse is expected to increase immediately after activity but by no more than 50 bpm if it is strenuous activity. The diastolic blood pressure is expected to rise but by no more than 15 mm Hg. The pulse returns to within 6 bpm of the resting pulse after 3 minutes of rest.

CN: Physiological adaptation; CL: Evaluate

22. 3. The nurse should continue to monitor the client because this value reflects a normal physiologic response. The **HCP**  does not need to be called, and oxygen does not need to be started based on these laboratory findings. Immediately after surgery, the client's hematocrit reflects a falsely high value related to the body's compensatory response to the stress of sudden loss of fluids and blood. Activation of the intrinsic pathway and the renin-angiotensin cycle via antidiuretic hormone produces vasoconstriction and retention of fluid for the first 1 to 2 days postoperatively. By the 2nd to 3rd day, this response decreases, and the client's hematocrit level is more reflective of the amount of RBCs in the plasma. Fresh bleeding is a less likely occurrence on the third postoperative day but is not impossible; however, the nurse should have expected to see a decrease in the RBC count and hemoglobin value accompanying the hematocrit.

CN: Physiological adaptation; CL: Synthesize

23. 4. The most likely time for a blood transfusion reaction to occur is during the first 15 minutes or first 50 mL of the infusion. If a blood transfusion reaction does occur, it is imperative to keep an established IV line so that medication can be administered to prevent or treat cardiovascular collapse in case of anaphylaxis. PRBCs should be administered through a 19-gauge or larger needle; a peripherally inserted central catheter line is not recommended, in order to avoid a slow flow. RBCs will hemolyze in dextrose or lactated Ringer's solution and should be infused with only normal

saline solution.

CN: Pharmacological and parenteral therapies; CL: Synthesize

24. 1,2,4. The nurse should teach the client to drink plenty of fluids to avoid becoming dehydrated. The client should avoid being in high altitudes, such as mountains above 5,000 feet (1,524 m), where less oxygen is available and may precipitate a sickle cell crisis. The nurse should alert young women with sickle cell anemia that pregnancy increases the risk of a crisis. People who are homozygous for HbS have sickle cell anemia; the heterozygous form is the sickle cell carrier trait. A client with sickle cell anemia may fly on - commercial airlines; the airplane is pressurized and has an adequate oxygen level.

CN: Health promotion and maintenance; CL: Synthesize

25. 2. The nurse should teach the client and family that individuals who are heterozygous for hemochromatosis rarely develop the disease. Men and women are equally at risk for hemochromatosis, but men are diagnosed earlier because women do not usually have manifestations until menopause. Hemochromatosis is the most common genetic disorder in Canada and the United States. Individuals who are homozygous for hemochromatosis received a defective gene from each parent. Those with homozygous genes may develop the disease.

CN: Health promotion and maintenance; CL: Synthesize

26. 3,4,1,2. When the client is having a blood transfusion reaction, the nurse should first stop the transfusion and then keep the IV open with normal saline infusion. Next, the nurse should notify the **HCP**  and blood bank and then complete the required form(s) regarding the transfusion reaction.

CN: Physiological adaptation; CL: Synthesize

27. 2,3,5. The American Association of Blood Banks and Canadian Blood Services recommend that two qualified people, such as two **registered nurses (RN)** , compare the name and number on the identification bracelet with the tag on the blood bag. Verifying that the two units are the same is not a recommendation. Rather, the verification is always with the client, not with bags of blood. A unit of blood should infuse in 4 hours or less to avoid the

risk of septicemia since no preservatives are used. When a blood transfusion reaction occurs, the blood transfusion should be stopped immediately, but the IV line should be kept open so that emergency medications and fluids can be administered.

The unit of PRBCs should be inspected for contamination by looking for leaks, abnormal color, clots, and excessive air bubbles. When a unit of PRBCs is being transfused, vital signs are assessed before the transfusion begins, after the first 15 minutes and then every hour until 1 hour after the transfusion has been completed. When PRBCs are being administered, a 20-gauge or larger needle is needed to avoid destroying the red blood cells (RBCs) passing through the lumen and to allow for maximal flow rate.

CN: Pharmacological and parenteral therapies; CL: Synthesize

28. 2. ABO- and Rh-incompatible blood causes an antigen-antibody reaction that produces hemolysis or agglutination of red blood cells (RBCs). At the first indication of any sign/symptom of reaction, the blood transfusion is stopped. Blood and urine samples are obtained from the client and sent to the lab along with the remaining untransfused blood. Hemoglobin in the urine and blood samples taken at the time of the reaction provides evidence of a hemolytic blood transfusion reaction. Antihistamine, aspirin, diuretics, and vasopressors may be administered with different types of transfusion reactions.

CN: Reduction of risk potential; CL: Synthesize

29. 1. Epoetin is a recombinant DNA form of erythropoietin, which stimulates the production of red blood cells (RBCs) and therefore causes the hematocrit to rise. The elevation in hematocrit causes an elevation in the blood pressure; therefore, the blood pressure is a vital sign that should be checked. The partial thromboplastin time, hemoglobin level, and prothrombin time are not monitored for this drug.

CN: Pharmacological and parenteral therapies; CL: Analyze

30. 4,5,6. Erythropoietin is administered to decrease the need for blood transfusions by stimulating red blood cell (RBC) production. The medication should be administered through the IV line without other medications to avoid a reaction. The hematocrit, a simple measurement of the percentage of

RBCs in the total blood volume, is used to monitor this therapy. When initiating IV erythropoietin therapy, the nurse should monitor the hematocrit level so that it rises no more than four points in any 2-week period. In addition, the initial doses of erythropoietin are adjusted according to the client's changes in blood pressure. The nurse should tell the client to avoid driving and performing hazardous activity during the initial treatment due to possible dizziness and headaches secondary to the adverse effect of hypertension. The hematocrit, not the hemoglobin level, is used for monitoring the effectiveness of therapy. The vial of erythropoietin should not be shaken because it may be biologically inactive. The solution should not be used if it is discolored. The nurse should not re-enter the vial once it has been entered; it is a one-time use vial. All remaining erythropoietin should be discarded since it does not contain preservatives.

CN: Pharmacological and parenteral therapies; CL: Synthesize

31. 4. Vitamin B₁₂ is a water-soluble vitamin. When water-soluble vitamins are taken in excess of the body's needs, they are filtered through the kidneys and excreted. Vitamin B₁₂ is considered to be nontoxic. Adverse reactions that have occurred are believed to be related to impurities or to the preservative in B₁₂ preparations. Ringing in the ears, rash, and nausea are not considered to be related to vitamin B₁₂ administration.

CN: Pharmacological and parenteral therapies; CL: Synthesize

32. 1,2,3,5. Eggs are a source of iron, but may not be well absorbed. Brown rice is a source of iron from plant sources (nonheme iron). Other sources of nonheme iron are whole-grain cereals and breads, dark green vegetables, legumes, nuts, dried fruits (apricots, raisins, dates), oatmeal, and sweet potatoes. Tea contains tannin, which combines with nonheme iron, preventing its absorption.

CN: Physiological adaptation; CL: Apply

33. 2. Macrocytic anemias can result from deficiencies in vitamin B₁₂ or ascorbic acid. Only vitamin B₁₂ deficiency causes diminished sensations of peripheral nerve endings. The nurse should assess for peripheral neuropathy and instruct the client in self-care activities for diminished sensation to heat

and pain (e.g., using a heating pad at a lower heat setting, making frequent checks to protect against skin trauma). The burn could be related to abuse, but this conclusion would require more supporting data. The findings should be documented, but the nurse would want to address the client's sensations first. The decision of how to treat the burn should be determined by the **healthcare provider (HCP)** 📖.

🔑 CN: Reduction of risk potential; CL: Synthesize

34. 3. Pruritus is a late symptom that results from abnormal histamine metabolism. Headache and dizziness are early symptoms from engorged veins. Shortness of breath is an early symptom from congested mucous membranes and ineffective gas exchange.

🔑 CN: Physiological adaptation; CL: Analyze

35. 1. Aplastic anemia decreases the bone marrow production of red blood cells (RBCs), white blood cells, and platelets. The client is at risk for bruising and bleeding tendencies. A change in the client's intake and output is important, but assessment for the potential for bleeding takes priority. Change in the peripheral nervous system is a priority problem specific to clients with vitamin B₁₂ deficiency. Change in bowel function is not associated with aplastic anemia.

🔑 CN: Physiological adaptation; CL: Synthesize

The Client with Platelet Disorders

36. 3. A dose of 0.5 mg of protamine sulfate reverses a 100-unit dose of heparin within 20 minutes. The nurse should administer protamine sulfate by IV push slowly to avoid adverse effects, such as hypotension, dyspnea, bradycardia, and anaphylaxis.

🔑 CN: Pharmacological and parenteral therapies; CL: Evaluate

37. 1,3,4,5. Underweight older adults may have little subcutaneous tissue, so the area around the anterior iliac crest is a suitable site for these clients. The nurse should use a 27-G, 5/8" (1.6-cm) needle. Cephalosporin and penicillin potentiate the effects of heparin. Some agency medication safety policies require two nurses check the dose because a dose error could cause

bleeding. The onset of heparin is not immediate when given subcutaneously.

CN: Pharmacological and parenteral therapies; CL: Apply

38. 1. A client with a platelet count of 30,000 to 50,000/ μL (30 to $50 \times 10^9/\text{L}$) is susceptible to bruising with minor trauma. Padding areas that the client might bump, scratch, or hit may help prevent minor trauma. A platelet count of 15,000 to 30,000/ μL (15 to $30 \times 10^9/\text{L}$) may result in spontaneous petechiae and bruising, especially on the extremities. Padding measures would still be used, but the focus would be on assessing for new spontaneous petechiae. Although the client should use precautions to prevent infection, the white blood count is not affected, and the client does not need to wear a mask when in areas where there are large numbers of people who are sources of potential infection. With a count below 20,000/ μL ($20 \times 10^9/\text{L}$), the client is at risk for spontaneous bleeding from the mucous membranes and intracranial bleeding.

CN: Reduction of risk potential; CL: Synthesize

39. 4. A recent viral infection in a female client between the ages of 20 and 30 with a history of systemic lupus erythematosus and an insidious onset of diffuse petechiae are hallmarks of idiopathic thrombocytopenic purpura. It is important to ask whether the client's recent menses have been lengthened or are heavier. Determining her ability to clot can help determine her risk of increased bleeding tendency until a platelet count is drawn. Petechiae are not caused by poor nutrition. Because of poor food and fluid intake or weakness and fatigue, the client may have gotten bruises from falling or bumping into things, but not petechiae.

CN: Reduction of risk potential; CL: Analyze

40. 2. When the platelet count is very low, red blood cells (RBCs) leak out of the blood vessels and into the tissue. If the blood pressure is elevated and the platelet count falls to $<15,000/\mu\text{L}$ ($15 \times 10^9/\text{L}$), internal bleeding in the brain can occur. A severe headache occurs from meningeal irritation when blood leaks out of the cerebral vasculature. When a client has thrombocytopenia, the nurse should always assess for cerebral bleeding by checking vital signs and performing neurologic checks. Headaches can be caused by stress, migraines, and sinus congestion. However, the concern here

is the risk of internal bleeding into the brain.

CN: Health promotion and maintenance; CL: Analyze

41. 2. Large, purplish skin lesions caused by hemorrhage are called ecchymoses. Small, flat, red pinpoint lesions are petechiae. Numerous petechiae result in a reddish, bruised appearance called purpura. An abrasion is a wound caused by scraping.

CN: Health promotion and maintenance; CL: Evaluate

42. 2. When the platelet count is $<150,000/\mu\text{L}$ ($150 \times 10^9/\text{L}$), prolonged bleeding can occur from trauma, injury, or straining such as with Valsalva's maneuver. Clients should avoid any activity that causes straining to evacuate the bowel. Clients can ambulate, but pointed or sharp surfaces should be padded. Clients can visit with their families but should avoid any scratches, bumps, or scrapes. Clients can sit in a semi-Fowler's position but should change positions to promote circulation and check for petechiae.

CN: Health promotion and maintenance; CL: Synthesize

43. 4. Aspirin has an antiplatelet effect, and bleeding time can consequently be prolonged. Intermittent use of ice packs to the site may stop the bleeding; ice causes blood vessels to vasoconstrict. Use of lukewarm water, patting the injury, and wrapping the entire forearm do not promote vasoconstriction to stop bleeding.

CN: Pharmacological and parenteral therapies; CL: Synthesize

44. 2. The client who states that the test results are normal has only heard that the bone marrow is functioning. The etiology is in the destruction of circulating platelets. Further tests must be completed to determine the cause (e.g., a coating of the platelets with antibodies that are seen as foreign bodies). The bone marrow result does rule out other potential diagnoses such as anemia, leukemia, or myeloproliferative disorders that involve bone marrow depression. The client needs to stop flossing and throw away his hard toothbrush, which can lead to bleeding of the gums. The destruction of the circulating platelets accounts for the easy bruising and the need to protect oneself from further bruising. The client should not jump or increase exertion of joints, which may lead to bleeding in the joints and joint pain.

CN: Reduction of risk potential; CL: Evaluate

45. 1. The nurse should assess the client who is bleeding for tachycardia because the heart beats faster to compensate for decreased circulating volume and decreased numbers of oxygen-carrying red blood cells (RBCs). The degree of cardiopulmonary distress and anemia will be related to the amount of hemorrhage that occurred and the period of time over which it occurred. Bradycardia is a late symptom of hemorrhage; it occurs after the client is no longer able to compensate and is debilitating further into shock. If bradycardia is left untreated, the client will die from cardiovascular collapse. Decreased Paco_2 is a late symptom of hemorrhage, after transport of oxygen to the tissue has been affected. A narrowed pulse pressure is not an early sign of hemorrhage.

CN: Physiological adaptation; CL: Analyze

46. 4. ITP is treated with steroids to suppress the splenic macrophages from phagocytizing the antibody-coated platelets, which are recognized as foreign bodies, so that the platelets live longer. The steroids also suppress the binding of the autoimmune antibody to the platelet surface. Steroids do not destroy the antibodies on the platelets, neutralize antigens, or increase phagocytosis.

CN: Pharmacological and parenteral therapies; CL: Apply

47. 3. The client needs to wear or carry information containing the name of the drug, dosage, **healthcare provider (HCP)**  and contact information, and emergency instructions because additional corticosteroid drug therapy would be needed during emergency situations. Prednisone should be taken in the morning because it can cause insomnia and because exogenous corticosteroid suppression of the adrenal cortex is less when it is administered in the morning. Prednisone must never be stopped suddenly. It must be tapered off to allow for the adrenal cortex to recover from drug-induced atrophy so that it can resume its function. Prednisone suppresses the immune response and masks infections. It does not provide extra protection against infection.

CN: Pharmacological and parenteral therapies; CL: Evaluate

48. 1. Nausea, vomiting, and peptic ulcers are gastrointestinal adverse effects of prednisone, so it is recommended that clients take the prednisone with food. In some instances, the client may be advised to take a prescribed antacid prophylactically. The client should never take over-the-counter drugs without notifying the **healthcare provider (HCP)**  who prescribed the prednisone. The client should ask the HCP about the amount and kind of exercise because of the need to establish baseline physical values before starting an exercise program and because of the increased potential for comorbidity with increasing age. The client should eat foods that are high in potassium to prevent hypokalemia.

 CN: Pharmacological and parenteral therapies; CL: Synthesize

49. 4. The best exercise for females who are on long-term corticosteroid therapy is a low-impact, weight-bearing exercise such as walking or weight lifting. Floor exercises do not provide for the weight bearing. Stretching is appropriate but does not offer sufficient weight bearing. Running provides for weight bearing but is hard on the joints and may cause bleeding.

 CN: Pharmacological and parenteral therapies; CL: Synthesize

50. 2. The client needs further teaching if she thinks that the number of tissues saturated represents all of the blood lost during a nosebleed. During a nosebleed, a significant amount of blood can be swallowed and go undetected. It is important that clients with severe thrombocytopenia do not take a nosebleed lightly. Clients with thrombocytopenia can apply pressure for 5 to 10 minutes over a small, superficial cut. Clients with thrombocytopenia can take hormones to suppress menses and control menstrual blood loss. Clients can also count the number of saturated sanitary napkins to approximate blood loss during menses. Some authorities estimate that a completely soaked sanitary napkin holds 50 mL.

 CN: Reduction of risk potential; CL: Evaluate

51. 2,4,5,6. Adverse effects of prednisone are weight gain, retention of sodium and fluids with hypertension and cushingoid features, a low serum albumin level, suppressed inflammatory processes with masked symptoms, and osteoporosis. A diet high in protein, potassium, calcium, and vitamin D is recommended. Carbohydrates would elevate glucose and further compromise

a client's immune status. Trans fat does not counteract the adverse effects of steroids such as prednisone.

CN: Pharmacological and parenteral therapies; CL: Synthesize

52. 1. Platelets cannot survive cold temperatures. The platelets should be stored at room temperature and last for no more than 5 days.

CN: Pharmacological and parenteral therapies; CL: Synthesize

53. 3. The bag containing platelets needs to be gently rotated to prevent clumping. ABO compatibility is not a necessary requirement, but human leukocyte antigen (HLA) matching of lymphocytes may be completed to avoid development of anti-HLA antibodies when multiple platelet transfusions are necessary. Platelets should be administered as fast as can be tolerated by the client to avoid aggregation. Most institutions use tubing especially for platelets instead of tubing for blood and blood products.

CN: Pharmacological and parenteral therapies; CL: Synthesize

54. 4. The correct technique for deep breathing postoperatively to avoid atelectasis and pneumonia is to take in a deep breath through the nose, hold it for 5 seconds, and then blow it out through pursed lips. The goal is to fully expand and empty the lungs for pulmonary hygiene.

CN: Reduction of risk potential; CL: Evaluate

55. 3. An elective surgical procedure is scheduled in advance so that all preparations can be completed ahead of time. The vital signs are the final check that must be completed before the client leaves the room so that continuity of care and assessment is provided for. The first assessment that will be completed in the preoperative holding area or operating room will be the client's vital signs. The client should have emptied the bladder before receiving preoperative medications so that the bladder is empty when it is time for transport into the operating room. The client should have signed the **consent** before the transport time so that if there were any questions or concerns, there was time to meet with the surgeon. Also, the consent form must be signed before any sedative medications are given. The client's name band should be placed as soon as the client arrives in the perioperative setting, and it remains in place through discharge.

CN: Physiological adaptation; CL: Analyze

56. 3. After a splenectomy, the client is at high risk for hypovolemia and hemorrhage. The dressing should be checked often; if drainage is present, a circle should be drawn around the drainage and the time noted to help determine how fast bleeding is occurring. The nasogastric tube should be connected, but this can wait until the dressing has been checked. A urinary catheter is not needed. The last pain medication administration and the client's current pain level should be communicated in the exchange report. Checking for hemorrhage is a greater priority than assessing pain level.

CN: Physiological adaptation; CL: Analyze

57. 3. A splenectomy may involve manipulation of the upper abdominal organs, such as diaphragm, stomach, liver, spleen, and small intestines. Manipulation of these organs and resulting inflammation lead to a slowed peristalsis. An NG tube is placed to decrease abdominal distention in the immediate postoperative phase. The stomach does not need to be manipulated away from the spleen postoperatively, nor would an NG tube accomplish this. The NG tube drains gastric contents and air in the stomach; it is not in the operative site and therefore cannot be used to irrigate it. The gastric juices are not checked as an indicator that peristalsis has returned; instead, bowel sounds are auscultated in all four quadrants to indicate the return of peristalsis.

CN: Physiological adaptation; CL: Apply

58. 4. Clients who have had a splenectomy are especially prone to infection. The reduction of immunoglobulin M leaves the client especially at risk for immunologic deficiency infections. All clients who have had major abdominal surgery usually receive discharge instructions not to drive because the stomach muscles are not strong enough to brake hard or quickly after the abdominal muscles have been separated. All clients need to pace activity and rest when going home after major surgery. Rest and sleep allow the growth hormone to repair the tissue, and activity allows the energy and strength to build endurance and muscle strength. An appointment is usually made to see the surgeon in the office 1 week after discharge for follow-up and to remove sutures or staples if this has not already been done.

 CN: Reduction of risk potential; CL: Synthesize

59. 2. There is no well-defined sequence for acute DIC other than that the client starts bleeding without a history or cause and does not stop bleeding. Later signs may include severe shortness of breath, hypotension, pallor, petechiae, hematoma, orthopnea, hematuria, vision changes, and joint pain.

 CN: Physiological adaptation; CL: Analyze

60. 3. DIC has not been found to respond to oral anticoagulants such as warfarin sodium. Treatments for DIC are controversial but include treating the underlying cause, administering heparin, and replacing depleted blood products.

 CN: Pharmacological and parenteral therapies; CL: Synthesize

61. 2. Clinical manifestations of microvascular thrombosis are those that represent a blockage of blood flow and oxygenation to the tissue that results in eventual death of the organ. Examples of microvascular thrombosis include acute respiratory distress syndrome, focal ischemia, superficial gangrene, oliguria, azotemia, cortical necrosis, acute ulceration, delirium, and coma. Hemoptysis, petechiae, and hematuria are signs of hemorrhage.

 CN: Physiological adaptation; CL: Analyze

62. 3. As blood collects in the peritoneal cavity, it causes dilation and distention, which is reflected in increased abdominal girth. The client would be tachycardic and hypotensive. Petechiae reflect bleeding in the skin.

 CN: Physiological adaptation; CL: Analyze

The Client with White Blood Cell Disorders

63. 1,2,3,5. The nurse should teach this client to stay on bed rest as long as there is a fever, gargle with warm saline, and increase oral fluids to prevent dehydration from the elevated temperature. The client with an enlarged spleen should avoid contact sports due to the increased risk of injury due to the enlargement. The client does not need to wear a mask, but should observe handwashing procedures.

 CN: Basic care and comfort; CL: Create

64. 4. The client will need a prescription from the **healthcare provider (HCP)**  to be placed in reverse (protective) isolation because the normal defenses are ineffective and place the client at risk for infection (leukopenia, $<5,000 \text{ cells}/\mu\text{L}$ [$5 \times 10^9/\text{L}$]). The faster the decrease in WBCs, the greater the bone marrow suppression and the more susceptible the client is to infection from not only pathogenic but also nonpathogenic organisms. The client will continue to be monitored, the laboratory may be called, and the report will be placed on the chart, but protection of the client must be instituted immediately.

 CN: Physiological adaptation; CL: Synthesize

65. 3. A shift to the left means that more immature than mature WBCs are at the site of inflammation or infection. Immature WBCs are less effective at phagocytosis and do not produce classic signs of inflammation, such as pus, redness, swelling, or heat. Fever is the only sign; therefore, it is a significant sign of infection in a client with immature or depressed WBCs.

 CN: Physiological adaptation; CL: Analyze

66. 1,2,3,4. Nursing care of a client with leukemia includes managing and preventing infection, maintaining integrity of skin and mucous membranes, instituting measures to prevent bleeding, and monitoring for bleeding. Aspirin is an anticoagulant; bleeding tendencies, such as petechiae, ecchymosis, epistaxis, gingival bleeding, and retinal hemorrhages, are likely due to thrombocytopenia.

 CN: Reduction of risk potential; CL: Create

67. 2. A client is at moderate risk when the ANC is $<1,000$ ($1 \times 10^9/\text{L}$). The ANC decreases proportionately to the increased risk for infection. Normal risk for infection is when the ANC is $1,500$ ($1.5 \times 10^9/\text{L}$) or greater. High risk for infection is when the ANC is <500 ($0.5 \times 10^9/\text{L}$). An ANC of 100 ($0.1 \times 10^9/\text{L}$) or less is life threatening.

 CN: Physiological adaptation; CL: Analyze

68. 1. Bedside rails, call bells, drug administration controls operated by the client, and other surface areas are frequently touched by caregivers with used

gloves. Changing gloves immediately after use protects the client from contamination by organisms. Cross-contamination is a break in technique of serious consequence to the severely compromised client. Standing 2 feet (61 cm) from the client, speaking minimally, and wearing protective covering shirts are not required in standard interventions for risk of infection.

 CN: Safety and infection control; CL: Synthesize

69. 1. The neutropenic client is at risk for infection, especially bacterial infection of the respiratory and gastrointestinal tracts. Breaks in the mucous membranes, such as those that could be caused by the insertion of a suppository or enema tube, would be a break in the first line of the body's defense and a direct port of entry for infection. The client with neutropenia is encouraged to wear an HEPA filter mask and to use an incentive spirometer for pulmonary hygiene. The client needs to know the importance of completing meticulous total body hygiene daily, including perianal care after every bowel movement, to decrease the flora at normal body orifices. The client also needs to know the importance of performing oral care after every meal and every 4 hours while the client is awake to decrease the bacterial buildup in the oropharynx.

 CN: Health promotion and maintenance; CL: Synthesize

70. 2. Washing hands before, during, and after care has a significant effect in reducing infections. It is advisable to avoid introducing a cold or children's germs and to avoid kissing the client, but the primary prevention technique is handwashing.

 CN: Health promotion and maintenance; CL: Synthesize

71. 1,2,4,5. The nurse can serve as a witness for **consent** for procedures. The nurse also ascertains whether the client has an understanding that is consistent with the procedure listed on the form, determines that the client is signing the consent of his or her own free will, and determines that the client understands postprocedure care. The nurse's role does not include explaining the risks of the procedure; that responsibility belongs to the person who is to perform the procedure, such as the **healthcare provider (HCP)** .

 CN: Management of care; CL: Synthesize

72. 3. As the bone marrow is being aspirated, the client will feel a suction or pulling type of sensation or discomfort that lasts a few seconds. A systemic premedication may be given to decrease this discomfort. A small area over the sternum is cleaned with an antiseptic. It is unnecessary to paint the entire anterior chest. The local anesthetic is injected through the subcutaneous tissue to numb the tissue for the larger-bore needle that is used for aspiration and biopsy. After the needle is removed, pressure is held over the aspiration site for 5 to 10 minutes to achieve hemostasis. A small dressing is applied; a large pressure dressing, such as an Ace bandage, would restrict the expansion of the lungs and is not used.

CN: Psychosocial adaptation; CL: Apply

73. 4. After a bone marrow aspiration, the puncture site should be checked every 10 to 15 minutes for bleeding. For a short period after the procedure, bed rest may be prescribed. Signs of infection, such as redness and swelling, are not anticipated at the aspiration site. A mild analgesic may be prescribed for pain, but if the client has pain longer than 24 hours, the nurse should assess the client for internal bleeding or increased pressure at the puncture site, which may be the cause of the pain, and should consult the **healthcare provider (HCP)** .

CN: Physiological adaptation; CL: Evaluate

74. 2. The nurse is an advocate for the client with leukemia who can be empowered with knowledge of the treatment. Immunologic, cytogenic, morphologic, histochemical, and other means are used to identify cell subtypes and stages of leukemia cell development for very specific and optimal treatment. The nurse should not label the client's feeling, such as frustration or emotional; only the client can identify her own feelings. Chastising the client is not helpful. It disavows the client's emotional state and responses to her diagnosis and involved treatment. Unless nurses have had leukemia, they cannot possibly know how the client feels even though they may be trying to offer her empathy.

CN: Psychosocial adaptation; CL: Synthesize

75. 3. The induction phase of chemotherapy is an aggressive treatment to kill leukemia cells. The client is severely immunocompromised and severely

at risk for infection. Flowers, herbs, and plants should be avoided during this time. The client's Bible, pictures, and other personal belongings can be cleaned before being brought into the room to prevent client contact with pathogenic and nonpathogenic organisms.

CN: Safety and infection control; CL: Synthesize

76. 2. The nurse identifies that the client does not understand that contact with animals must be avoided because they carry infection and the induction therapy will destroy the client's white blood cells (WBCs). The induction therapy will cause anemia, and the client will experience fatigue and will have to pace activities with rest periods. Platelet production will be decreased, and the client will be at risk for bleeding tendencies; oral hygiene will have to be provided by using a warm saline gargle instead of brushing the teeth and gums. The client will be at risk for infection owing to the decrease in WBC production and should report a temperature of 100°F (37.8°C) or higher.

CN: Safety and infection control; CL: Evaluate

77. 1. Imatinib works by inhibiting the proliferation of abnormal cells. Adverse effects include edema and GI irritation. Typical effects of this drug do not include numbness and tingling, bloody stools, or persistent cough. If the client has these symptoms, they may relate to disease occurrence or recurrence.

CN: Pharmacological and parenteral therapies; CL: Apply

78. 2. Diphenhydramine is an antihistamine. This drug helps reduce the incidence of an allergic response by blocking the release of histamine. Diphenhydramine also possesses anticholinergic effects and can reduce the incidence of nausea and vomiting for clients receiving chemotherapy. Although diphenhydramine may promote sleep, it is not the primary reason for its administration in this instance. Diphenhydramine will not reduce anxiety or potentiate the action of the vincristine.

CN: Pharmacological and parenteral therapies; CL: Apply

79. 1. Pancytopenia means a decrease in all blood components. Because a platelet count of $<15,000/\text{mm}^3$ can result in spontaneous bleeding, the nurse

notifies the **HCP**  of this laboratory result. Neutrophils are a type of WBC. An absolute neutrophil count between 1,000 and 1,800/mm³ suggests mild neutropenia and represents a low risk of infection. Although references vary, normal range for WBC counts is 5,000 to 11,000/mm³, and a female's normal hemoglobin (Hgb) value is roughly 12 to 16 g/100 mL. Therefore, the WBC count and Hgb levels are a bit low, but not critical.

CN: Pharmacological and parenteral therapies; CL: Analyze

80. 3. Antineoplastic agents can cause severe tissue damage if they extravasate; therefore, the nurse immediately stops the infusion and then notifies the **HCP** . If extravasation has occurred, it may be appropriate to apply ice packs to the site. Ice packs cause desired vasoconstriction; warm, moist packs cause vasodilation. Ice packs should not remain in place for more than 15 to 20 minutes because rebound vasodilation can occur; the ice packs are removed for a short time and then reapplied as needed.

CN: Pharmacological and parenteral Therapies; CL: Synthesize

81. 3,4,1,2. The client is experiencing a septic reaction to the blood transfusion. The nurse first stops the infusion and notifies the **HCP**  and blood bank; then, the nurse uses an infusion of normal saline to keep the vein open and follows by obtaining a sample of the client's blood for a blood culture. Lastly, the nurse sends the blood bag and the administration set to the blood bank for culture.

CN: Pharmacological and parenteral Therapies; CL: Synthesize

82. 2. Epoetin stimulates erythropoiesis and the production of RBCs. This is important for clients taking antineoplastics because they often suffer bone marrow depression as a side effect of antineoplastic therapy. Epoetin does not affect tissue malignancy or tumor size. Nausea and vomiting are commonly associated with antineoplastics, but these are treated with antiemetics.

CN: Pharmacological parenteral therapies; CL: Evaluate

83. 4. Bleeding and infection are the major complications and causes of death for clients with AML. Bleeding is related to the degree of thrombocytopenia, and infection is related to the degree of neutropenia. Cardiac arrhythmias rarely occur as a result of AML. Liver or renal failure

may occur, but neither is a major cause of death in AML.

 CN: Reduction of risk potential; CL: Synthesize

84. 1. The peak incidence of ALL is at 4 years of age. ALL is uncommon after 15 years of age. The median age at incidence of CML is 40 to 50 years. The peak incidence of AML occurs at 60 years of age. Two-thirds of cases of chronic lymphocytic leukemia occur in clients older than 60 years of age.

 CN: Physiological adaptation; CL: Analyze

85. 1. Clients with ALL are at risk for infection due to granulocytopenia. The nurse should place the client in a private room. Strict handwashing procedures should be enforced and will be the most effective way to prevent infection. It is not necessary to have the client wear a mask. The client is not contagious, and the staff does not need to wear gloves. The client can have visitors; however, they should be screened for infection and use handwashing procedures.

 CN: Physiological adaptation; CL: Synthesize

86. 3. Simple rinses with saline or a baking soda and water solution are effective and moisten the oral mucosa. Commercial mouthwashes and lemon glycerin swabs contain glycerin and alcohol, which are drying to the mucosa and should be avoided. Brushing after each meal is recommended, but every 4 hours may be too traumatic. During acute leukemia, the neutrophil and platelet counts are often low, and a soft-bristle toothbrush, instead of the client's usual brush, should be used to prevent bleeding gums.

 CN: Reduction of risk potential; CL: Synthesize

87. 3. The client with acute leukemia experiences fatigue and deconditioning. Lying in bed and taking deep breaths will not help achieve the goals. The client must get out of bed to increase activity tolerance and improve tidal volume. Ambulating in the hall (using an HEPA filter mask if neutropenic) is a sensible activity and helps improve conditioning. Sitting up in a chair facilitates lung expansion. Using a stationary bicycle in the room allows the client to increase activity as tolerated.

 CN: Reduction of risk potential; CL: Synthesize

88. 2. Combination chemotherapy does not mean two groups of drugs, one to kill the cancer cells and one to treat the adverse effects of the chemotherapy. Combination chemotherapy means that multiple drugs are given to interrupt the cell growth cycle at different points, decrease resistance to a chemotherapy agent, and minimize the toxicity associated with use of a high dose of a single agent (i.e., by using multiple agents with different toxicities).

CN: Pharmacological and parenteral therapies; CL: Evaluate

89. 1. The biliary system is not especially prone to hemorrhage. Thrombocytopenia (a low platelet count) leaves the client at risk for a potentially life-threatening spontaneous hemorrhage in the gastrointestinal, respiratory, and intracranial cavities.

CN: Physiological adaptation; CL: Analyze

90. 1. The primary purpose of reverse isolation is to reduce transmission of organisms to the client from sources outside the client's environment.

CN: Safety and infection control; CL: Apply

The Client with Lymphoma

91. 2. Painless and enlarged cervical lymph nodes, tachycardia, weight loss, weakness and fatigue, and night sweats are signs of Hodgkin's disease. Difficulty swallowing and breathing may occur, but only with mediastinal node involvement. Hepatomegaly is a late-stage manifestation.

CN: Physiological adaptation; CL: Analyze

92. 3. The client with Hodgkin's lymphoma who has had radiation therapy is prone to infection; therefore, the primary goal is to prevent infection. The nurse instructs the client to perform frequent hand hygiene, avoid crowded areas, and report a temperature over 100°F (37.7°C). Maintaining fluid balance, exercising, and maintaining mental health are also important, but not the primary goal at this time.

CN: Safety and infection control; CL: Synthesize

93. 1. The nurse must ensure that sterile technique is used when a biopsy

is obtained because the client is at high risk for infection. In most cases, a lymph node biopsy is sent immediately to the laboratory once it is placed in a specific solution in a closed container. It is not necessary to wear a gown and mask when obtaining the specimen. It is not necessary to use special handling procedures for the instruments used.

 CN: Management of care; CL: Apply

94. 3. Assessing for an open airway is always first. The procedure involves the neck; the anesthesia may have affected the swallowing reflex, or the inflammation may have closed in on the airway, leading to ineffective air exchange. Once a patent airway is confirmed and an effective breathing pattern established, the circulation is checked. Vital signs and the incision are assessed as soon as possible, but only after it is established that the airway is patent and the client is breathing normally. A neurologic assessment is completed as soon as possible after other important assessments.

 CN: Physiological adaptation; CL: Synthesize

95. 1. Herpes zoster infections are common in clients with Hodgkin's disease. Discoloring of the teeth is not related to Hodgkin's disease but rather to the ingestion of iron supplements or some antibiotics such as tetracycline. Mild anemia is common in Hodgkin's disease, but the platelet count is not affected until the tumor has invaded the bone marrow. A cellular immunity defect occurs in Hodgkin's disease in which there is little or no reaction to skin sensitivity tests. This is called anergy.

 CN: Physiological adaptation; CL: Analyze

96. 3. A temperature higher than 100.4°F (38°C), profuse night sweats, and an unintentional weight loss of 10% of body weight represent the cluster of clinical manifestations known as the B symptoms. Forty percent of clients with Hodgkin's disease have B symptoms, and B symptoms are more common in advanced stages of the disease.

 CN: Physiological adaptation; CL: Analyze

97. 1. Analgesics are used as needed to relieve painful encroachment of enlarged lymph nodes. Perfumed shower gel will increase pruritus. Wearing a mask does not protect the client from infection if pathogens are not spread by

airborne droplets. Antipyretics should be used to treat fever symptomatically after infection is ruled out.

CN: Health promotion and maintenance; CL: Create

98. 1. In the staging process, the designations A and B signify that symptoms were or were not present when Hodgkin's disease was found, respectively. The Roman numerals I through IV indicate the extent and location of involvement of the disease. Stage I indicates involvement of a single lymph node; stage II, two or more lymph nodes on the same side of the diaphragm; stage III, lymph node regions on both sides of the diaphragm; and stage IV, diffuse disease of one or more extralymphatic organs.

CN: Physiological adaptation; CL: Apply

99. 3. Encouraging the client to take slow, deep breaths during uncomfortable parts of procedures is the best method of decreasing the stress response of tightening and tensing the muscles. Slow, deep breathing affects the level of carbon dioxide in the brain to increase the client's sense of well-being. Allowing the client's family to stay may be appropriate if the family has a calming effect on the client, but this family is upset and may contribute to the client's stress. Silence can be therapeutic, but when the client is faced with a potentially life-threatening diagnosis and a new, invasive procedure, taking deep breaths will be more effective in reducing the stress response. Expressing feelings is important, but deep breathing will promote relaxation; the nurse can encourage the client to express feelings when the procedure is completed.

CN: Psychosocial adaptation; CL: Synthesize

100. 2. A biopsy needle is inserted through a separate incision in the anesthetized area. The client will feel a pressure sensation when the biopsy is taken but should not feel actual pain. The client should be instructed to inform the **healthcare provider (HCP)**  if pain is felt so that more anesthetic agent can be administered to keep the client comfortable. The biopsy is performed after the aspiration and from a slightly different site so that the tissue is not disturbed by either test. The client will feel a suction-type pain for a moment when the aspiration is being performed, not the biopsy. A small incision is made for the biopsy to accommodate the larger-

bore needle. This may require a stitch.

CN: Psychosocial adaptation; CL: Synthesize

101. 3. Terminally ill clients most often describe feelings of isolation because they tend to be ignored, they are often left out of conversations (especially those dealing with the future), and they sense the attitudes of discomfort that many people feel in their presence. Helpful nursing measures include taking the time to be with the client, offering opportunities to talk about feelings, and answering questions honestly.

CN: Psychosocial adaptation; CL: Synthesize

102. 2. It is incorrect that the survivor rate is directly proportional to the incidence of second malignancy. The survivor rate is indirectly proportional to the incidence of second malignancy, and regular screening is very important to detect a second malignancy, especially acute myeloid leukemia or myelodysplastic syndrome. Survivors should know the stage of the disease and their current treatment plan so that they can remain active participants in their health care.

CN: Physiological adaptation; CL: Evaluate

The Client Who Is in Shock

103. 3. Nursing interventions and collaborative management are focused on correcting and maintaining adequate tissue perfusion. Inadequate tissue perfusion may be caused by hemorrhage, as in hypovolemic shock; by decreased cardiac output, as in cardiogenic shock; or by massive vasodilation of the vascular bed, as in neurogenic, anaphylactic, and septic shock. Fluid deficit, not fluid overload, occurs in shock.

CN: Physiological adaptation; CL: Synthesize

104. 4. Typical signs and symptoms of hypovolemic shock include systolic blood pressure <90 mm Hg, narrowing pulse pressure, tachycardia, tachypnea, cool and clammy skin, decreased urine output, and mental status changes, such as irritability or anxiety. Unequal dilation of the pupils is related to central nervous system injury or possibly to a previous history of eye injury.

 CN: Physiological adaptation; CL: Analyze

105. 1. Urine output provides the most sensitive indication of the client's response to therapy for hypovolemic shock. Urine output should be consistently >35 mL/h. Blood pressure is a more accurate reflection of the adequacy of vasoconstriction than of tissue perfusion. Respiratory rate is not a sensitive indicator of fluid balance in the client recovering from hypovolemic shock.

 CN: Pharmacological and parenteral therapies; CL: Evaluate

106. 1. Causes of hypovolemic shock include external fluid loss, such as hemorrhage; internal fluid shifting, such as ascites and severe edema; and dehydration. Massive vasodilation is the initial phase of vasogenic or distributive shock, which can be further subdivided into three types of shock: septic, neurogenic, and anaphylactic. A severe antigen-antibody reaction occurs in anaphylactic shock. Gram-negative bacterial infection is the most common cause of septic shock. Loss of sympathetic tone (vasodilation) occurs in neurogenic shock.

 CN: Physiological adaptation; CL: Analyze

107. 2. The client who is receiving a blood product requires astute assessment for signs and symptoms of allergic reaction and anaphylaxis, including pruritus (itching), urticaria (hives), facial or glottal edema, and shortness of breath. If such a reaction occurs, the nurse should stop the transfusion immediately, but leave the IV line intact, and notify the **healthcare provider (HCP)** . Usually, an antihistamine (such as diphenhydramine hydrochloride) is administered. Epinephrine and corticosteroids may be administered in severe reactions. Fluid balance is not an immediate concern during the blood administration. The administration should not cause pain unless it is extravasating out of the vein, in which case the IV administration should be stopped. Administration of a unit of blood should not affect the level of consciousness.

 CN: Pharmacological and parenteral therapies; CL: Analyze

108. 2. At medium doses (4 to 8 mcg/kg/min), dopamine hydrochloride slightly increases the heart rate and improves contractility to increase cardiac

output and improve tissue perfusion. When given at low doses (0.5 to 3.0 mcg/kg/min), dopamine increases renal and mesenteric blood flow. At high doses (8 to 10 mcg/kg/min), dopamine produces vasoconstriction, which is an undesirable effect. Dopamine is not given to affect preload and afterload.

CN: Pharmacological and parenteral therapies; CL: Evaluate

109. 2. The client who is receiving dopamine hydrochloride requires continuous blood pressure monitoring with an invasive or noninvasive device. The nurse may titrate the IV infusion to maintain a systolic blood pressure of 90 mm Hg. Administration of a pain medication concurrently with dopamine hydrochloride, which is a potent sympathomimetic with dose-related alpha-adrenergic agonist, beta 1-selective adrenergic agonist, and dopaminergic blocking effects, is not an essential nursing action for a client who is in shock with already low hemodynamic values. Arterial blood gas concentrations should be monitored according to the client's respiratory status and acid-base balance status and are not directly related to the dopamine hydrochloride dosage. Monitoring for signs of infection is not related to the nursing action for the client receiving dopamine hydrochloride.

CN: Pharmacological and parenteral therapies; CL: Synthesize

110. 4,1,2,3. Analysis of the client's laboratory results indicates that an INR of 8 is increased beyond therapeutic ranges. The client is also experiencing severe acute rectal bleeding and has a hemoglobin level in the low range of normal and a hematocrit reflecting fluid volume loss. The nurse should first establish an IV line and administer the dextrose in saline. Next, the nurse should administer the FFP. FFP contains concentrated clotting factors and provides an immediate reversal of the prolonged INR. Vitamin K 2.5 mg PO should be given next because it reverses the warfarin by returning the PT to normal values. However, the reversal process occurs over 1 to 2 hours. Lastly, the nurse can schedule the client for the sigmoidoscopy.

CN: Pharmacological and parenteral therapies; CL: Synthesize

111. 2. Warm, flushed skin from a high cardiac output with vasodilation occurs in warm shock or the hyperdynamic phase (first phase) of septic shock. Other signs and symptoms of early septic shock include fever with restlessness and confusion; normal or decreased blood pressure with

tachypnea and tachycardia; increased or normal urine output; and nausea and vomiting or diarrhea. Cool, clammy skin occurs in the hypodynamic or cold phase (later phase). Hemorrhage is not a factor in septic shock.

CN: Physiological adaptation; CL: Analyze

112. 1. The nurse monitors the blood levels of antibiotics, white blood cells, serum creatinine, and blood urea nitrogen because of the decreased perfusion to the kidneys, which are responsible for filtering out the ceftriaxone sodium. It is possible that the clearance of the antibiotic has been decreased enough to cause toxicity. Increased levels of these laboratory values should be reported to the **healthcare provider (HCP)**  immediately. A spinal fluid analysis is done to examine cerebral spinal fluid, but there is no indication of central nervous system involvement in this case. Arterial blood gases are used to determine actual blood gas levels and assess acid-base balance. Serum osmolality is used to monitor fluid and electrolyte balance.

CN: Pharmacological and parenteral therapies; CL: Analyze

113. 4. Maintaining asepsis of indwelling urinary catheters is essential to prevent infection. Preventing septic shock is a major focus of nursing care because the mortality rate for septic shock is as high as 90% in some populations. Very young and elderly clients (those younger than age 2 or older than age 65) are at increased risk for septic shock. Administering IV fluid replacement therapy, obtaining vital signs every 4 hours on all clients, and monitoring red blood cell counts for elevation do not pertain to septic shock prevention.

CN: Safety and infection control; CL: Synthesize

114. 2. ARDS is a complication associated with septic shock. ARDS causes respiratory failure and may lead to death, even after the client has recovered from shock. Anaphylaxis is a type of distributive or vasogenic shock. COPD is a functional category of pulmonary disease that consists of persistent obstruction of bronchial airflow and involves chronic bronchitis and chronic emphysema. Mitral valve prolapse is a condition in which the mitral valve is pushed back too far during ventricular contraction.

CN: Physiological adaptation; CL: Analyze

Managing Care, Quality, and Safety for Clients with Hematologic Health Problems

115. 3. When two clients are to receive blood at the same time, the nurse should call for and hang the clients' transfusions separately to avoid error. The nurse should call for and hang the first client's blood first because this client has experienced a change in blood pressure over a short period of time. The nurse should next call and hang the second client's blood transfusion as there is no indication that this client is unstable at this time. The nurse should not call for both units of transfusions at the same time due to the increased risk of misidentification. The nurse should not verify compatibility of both units at the same time due to the increased risk of misidentification. It is not necessary to involve two nurses because the second client can wait until the nurse has time to hang the blood.

CN: Management of care; CL: Synthesize

116. 1,2,3,4. If a blood transfusion is terminated, the nurse must send a freshly collected blood sample to the blood bank and a urine sample to the laboratory; the nurse must send the blood component unit with the attached administration set and completed Transfusion Reaction Form to the blood bank. It is not necessary to inform Infection Control, but the Risk Management department should be notified, since a transfusion reaction may be a significant liability issue.

CN: Reduction of risk potential; CL: Synthesize

117. 3. The most current pharmacology information is found in the clinical agency's drug guide, which may be available on electronic sources that are frequently updated and can be transmitted to a handheld device or by logging into the Internet or hospital's intranet, if available. A commercially published drug guide and pharmacology textbooks are outdated once published and, therefore, may not have current information. The manufacturer's website has the potential for bias.

CN: Safety and infection control; CL: Apply

118. 1,2,3. Abbreviations can be misinterpreted and all healthcare professionals should avoid the use of easily misunderstood abbreviations. The purpose of avoiding abbreviations is not to make it easier for clients to understand the medication prescriptions or to make data entry easier.

CN: Safety and infection control; CL: Synthesize

119. 4. The most common source of infection and microbial colonization in neutropenic clients is their own nonpathogenic normal flora. Attention to personal hygiene, such as oral, pulmonary, urinary, and rectal care, is essential. It is important to acknowledge the client's concerns and fears and to provide organized, calm, compassionate care, but it is more important to teach the client how to prevent an infection that could be life threatening.

CN: Health promotion and maintenance; CL: Synthesize

The Client with Respiratory Health Problems

- Managing Care, Quality, and Safety of Clients with Respiratory Health Problems
- Answers, Rationales, and Test-Taking Strategies

The Client with an Upper Respiratory Tract Infection

1. A nurse is completing the health history for a client who has been taking Echinacea for a head cold. The client asks, “Why is this not helping me feel better?” Which response by the nurse would be the **most** accurate?

- ☐ **1.** “There is limited information as to the effectiveness of herbal products.”
- ☐ **2.** “Antibiotics are the agents needed to treat a head cold.”
- ☐ **3.** “The head cold should be gone within the month.”
- ☐ **4.** “Combining herbal products with prescription antiviral medications is sure to help you.”

2. A nurse is teaching a client about taking antihistamines. Which information should the nurse include in the teaching plan? Select all that apply.

- ☐ 1. Operating machinery and driving may be dangerous while taking antihistamines.
- ☐ 2. Continue taking antihistamines even if nasal infection develops.
- ☐ 3. The effect of antihistamines is not felt until a day later.
- ☐ 4. Do not use alcohol with antihistamines.
- ☐ 5. Increase fluid intake to 2,000 mL/day.

3. A nurse instructs a client with allergic rhinitis about the correct technique for using an intranasal inhaler. Which statement indicates that the client understands the instructions?

- ☐ 1. "I should limit the use of the inhaler to early morning and bedtime use."
- ☐ 2. "It is important to not shake the canister because that can damage the spray device."
- ☐ 3. "I should hold one nostril closed while I insert the spray into the other nostril."
- ☐ 4. "The inhaler tip is inserted into the nostril and pointed toward the inside nostril wall."

4. Which is an expected outcome for a client recovering from an upper respiratory tract infection? The client will:

- ☐ 1. maintain a fluid intake of 800 mL every 24 hours.
- ☐ 2. experience chills only once a day.
- ☐ 3. cough productively without chest discomfort.
- ☐ 4. experience less nasal obstruction and discharge.

5. The nurse teaches the client how to instill nose drops. Which technique is correct?

- ☐ 1. The client uses sterile technique when handling the dropper.
- ☐ 2. The client blows the nose gently before instilling drops.
- ☐ 3. The client uses a new dropper for each instillation.
- ☐ 4. The client sits in a semi-Fowler's position for 2 minutes.

6. The nurse should include which instructions in the teaching plan for a client with chronic sinusitis? Select all that apply.

- ☐ 1. Avoid the use of caffeinated beverages.
- ☐ 2. Perform postural drainage every day.
- ☐ 3. Take a hot shower in the morning and evening.
- ☐ 4. Report a temperature of 102°F (38.9°C) or higher.
- ☐ 5. Limit fluid intake to 1,000 mL per 24 hours.

7. A client with allergic rhinitis asks the nurse what to do to decrease rhinorrhea. Which instruction would be appropriate for the nurse to give the client?

- ☐ 1. “Use your nasal decongestant spray regularly to help clear your nasal passages.”
- ☐ 2. “Ask the healthcare provider for antibiotics. Antibiotics will help decrease the secretion.”
- ☐ 3. “It is important to increase your activity. A daily brisk walk will help promote drainage.”
- ☐ 4. “Keep a diary of when your symptoms occur. This can help you identify what precipitates your attacks.”

8. Guaifenesin 300 mg four times a day has been prescribed as an expectorant. The dosage strength of the liquid is 200 mg/5 mL. How many milliliters should the nurse administer for each dose? Record your answer using one decimal place. mL.

9. Pseudoephedrine has been prescribed as a nasal decongestant. What is a possible adverse effect of this drug?

- ☐ 1. constipation
- ☐ 2. bradycardia
- ☐ 3. diplopia
- ☐ 4. restlessness

The Client Undergoing Nasal Surgery

10. A healthcare provider (HCP) has just inserted nasal packing for a client with epistaxis. The client is taking ramipril for hypertension. What

should the nurse instruct the client to do?

- ☐ 1. Use 81 mg of aspirin daily for relief of discomfort.
- ☐ 2. Omit the next dose of ramipril.
- ☐ 3. Remove the packing if there is difficulty swallowing.
- ☐ 4. Avoid rigorous aerobic exercise.

11. A client had surgery for a deviated nasal septum. Which finding indicates that bleeding is occurring even if the nasal drip pad remains dry and intact?

- ☐ 1. nausea
- ☐ 2. repeated swallowing
- ☐ 3. increased respiratory rate
- ☐ 4. increased pain

12. A client who has undergone outpatient nasal surgery is ready for discharge and has nasal packing in place. The nurse should instruct the client to:

- ☐ 1. avoid activities that elicit Valsalva's maneuver.
- ☐ 2. take aspirin to control nasal discomfort.
- ☐ 3. avoid brushing the teeth until the nasal packing is removed.
- ☐ 4. apply heat to the nasal area to control swelling.

13. Which statement indicates to the nurse that a client has understood the discharge instructions provided after nasal surgery?

- ☐ 1. "I should not shower until my packing is removed."
- ☐ 2. "I will take stool softeners and modify my diet to prevent constipation."
- ☐ 3. "Coughing every 2 hours is important to prevent respiratory complications."
- ☐ 4. "It is important to blow my nose each day to remove the dried secretions."

14. The nurse is giving preoperative instructions to a client who will be undergoing rhinoplasty. The nurse should instruct the client that:

- ☐ 1. after surgery, nasal packing will be in place for 7 to 10 days.

- ☐ 2. normal saline nose drops will need to be administered preoperatively.
- ☐ 3. the results of the surgery will be immediately obvious postoperatively.
- ☐ 4. aspirin-containing medications should not be taken for 2 weeks before surgery.

15. Following nasal surgery, what should the nurse do **first**?

- ☐ 1. Assess the client's pain.
- ☐ 2. Inspect the area for periorbital ecchymosis.
- ☐ 3. Assess respiratory status.
- ☐ 4. Measure intake and output.

16. After nasal surgery, the client expresses concern about how to decrease facial pain and swelling while recovering at home. Which instruction would be **most** effective for decreasing pain and edema?

- ☐ 1. Take analgesics every 4 hours around the clock.
- ☐ 2. Use corticosteroid nasal spray as needed to control symptoms.
- ☐ 3. Use a bedside humidifier while sleeping.
- ☐ 4. Apply cold compresses to the area.

17. A client is being discharged with nasal packing in place. The nurse should instruct the client to:

- ☐ 1. perform frequent mouth care.
- ☐ 2. use normal saline nose drops daily.
- ☐ 3. sneeze and cough with mouth closed.
- ☐ 4. gargle every 4 hours with salt water.

18. The nurse is teaching a client how to manage a nosebleed. What instruction should the nurse give the client?

- ☐ 1. "Tilt your head backward, and pinch your nose."
- ☐ 2. "Lie down flat, and place an ice compress over the bridge of the nose."
- ☐ 3. "Blow your nose gently with your neck flexed."
- ☐ 4. "Sit down, lean forward, and pinch the soft portion of your nose."

19. An elderly client had posterior packing inserted to control a severe nosebleed. After insertion of the packing, the nurse should observe the client for which finding?

- ☐ 1. vertigo
- ☐ 2. Bell's palsy
- ☐ 3. hypoventilation
- ☐ 4. loss of gag reflex

The Client with Cancer of the Larynx

20. Following surgery for a radical neck dissection for laryngeal cancer, the **priority** for nursing care is:

- ☐ 1. maintaining complete bed rest until postsurgical swelling decreases.
- ☐ 2. taking vital signs once a shift until the client is stable.
- ☐ 3. starting a clear liquid diet at 48 hours.
- ☐ 4. suctioning the laryngectomy tube as often as needed.

21. A client who has had a total laryngectomy appears withdrawn and depressed. The client keeps the curtain drawn, refuses visitors, and indicates a desire to be left alone. Which nursing intervention would be **most** therapeutic for the client?

- ☐ 1. discussing the behavior with the spouse to determine the cause
- ☐ 2. exploring future plans
- ☐ 3. respecting the need for privacy
- ☐ 4. encouraging expression of feelings nonverbally and in writing

22. The nurse is suctioning a client who had a laryngectomy. What is the **maximum** amount of time the nurse should suction the client?

- ☐ 1. 10 seconds
- ☐ 2. 20 seconds
- ☐ 3. 25 seconds
- ☐ 4. 30 seconds

23. When suctioning a tracheostomy tube 3 days following insertion, what should the nurse do?

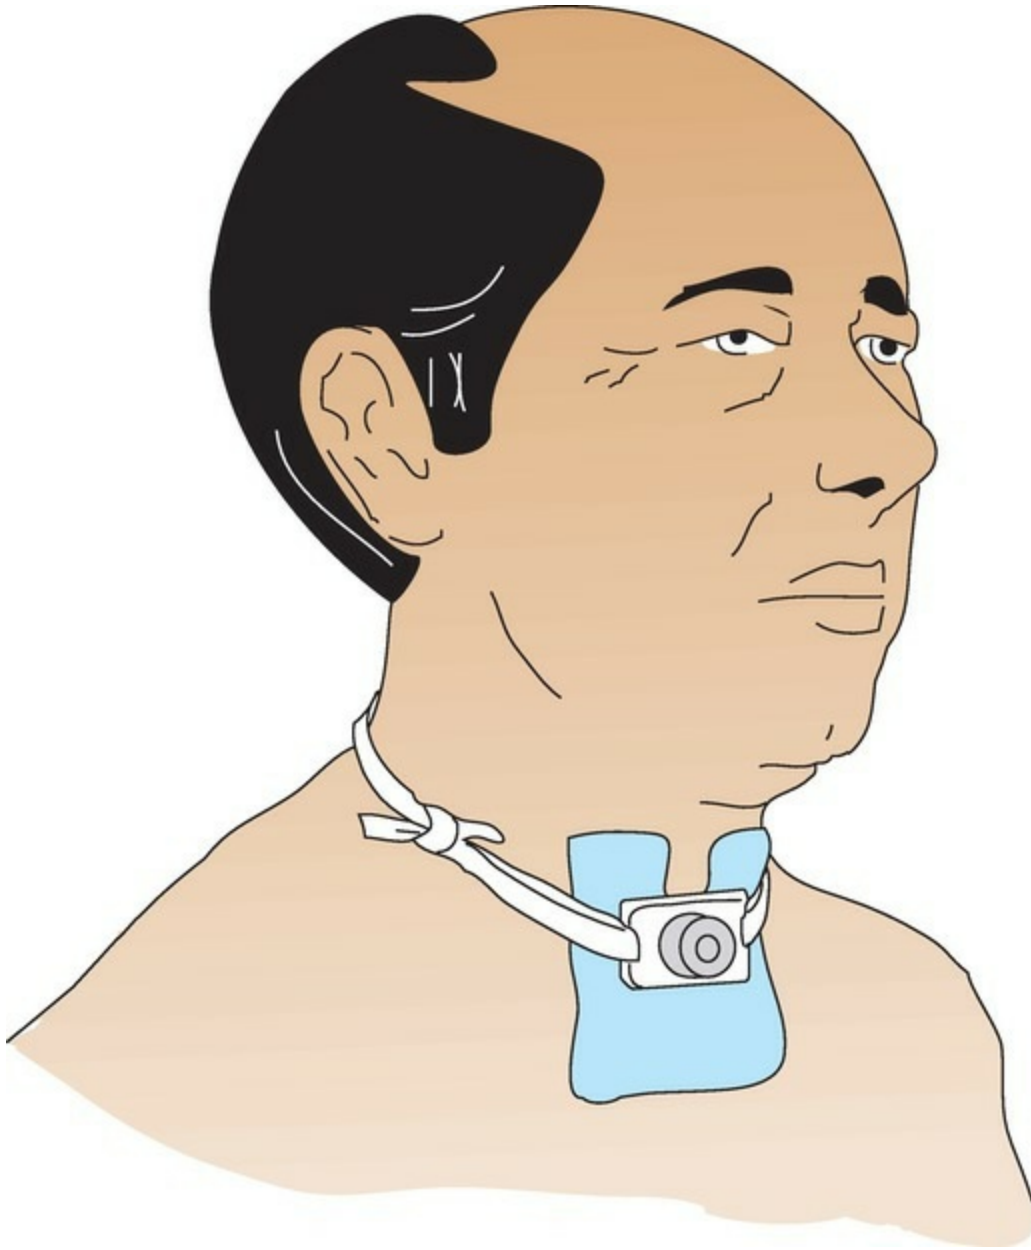

- ☐ 1. Use a sterile catheter each time the client is suctioned.
- ☐ 2. Clean the catheter in sterile water after each use, and reuse for no longer than 8 hours.

- ☐ **3.** Protect the catheter in sterile packaging between suctioning episodes.
- ☐ **4.** Use a clean catheter with each suctioning, and disinfect it in hydrogen peroxide between uses.

24. The client with a laryngectomy does not want to be observed by the family because the opening in the throat is “disgusting.” The nurse should:

- ☐ **1.** initiate teaching about the care of a stoma.
- ☐ **2.** explain that the stoma will not always look as it does now.
- ☐ **3.** inform the client of the benefits of family support at this time.
- ☐ **4.** explore why the client believes the stoma is “disgusting.”

25. The nurse team leader is making rounds and observes the client who had a tracheostomy tube inserted 2 days ago (see figure). The nursing policy manual recommends use of the gauze pad. The nurse should:

- ☐ 1. make sure the gauze pad is dry and the client is in a comfortable position.
- ☐ 2. ask the unlicensed assistive personnel (UAP) to tie the tracheostomy tube ties in the back of the client's neck.
- ☐ 3. reposition the gauze pad around the stoma with the open end downward.
- ☐ 4. ask a registered nurse (RN) to change the ties and position another gauze pad around the stoma.

26. To reduce the risk of laryngeal cancer in employees in a factory that

uses respiratory irritants, what instructions should the nurse give the employees? Select all that apply.

- ☐ 1. Stop smoking.
- ☐ 2. Use a portable HEPA air purifier in the home.
- ☐ 3. Limit alcohol intake.
- ☐ 4. Brush teeth after every meal.
- ☐ 5. Avoid raising the voice to be heard over the noise in the factory.

27. A client has had hoarseness for more than 2 weeks. The nurse should:

- ☐ 1. refer the client to a healthcare provider (HCP) for a prescription for an antibiotic.
- ☐ 2. instruct the client to gargle with salt water at home.
- ☐ 3. assess the client for dysphagia.
- ☐ 4. instruct the client to take a throat analgesic.

28. A client has just returned from the postanesthesia care unit after undergoing a laryngectomy. Which instruction should the nurse include in the plan of care?

- ☐ 1. Maintain the head of the bed at 30 to 40 degrees.
- ☐ 2. Teach the client how to use esophageal speech.
- ☐ 3. Initiate small feedings of soft foods.
- ☐ 4. Irrigate drainage tubes as needed.

29. Which goal is an expected outcome for a client recovering from a total laryngectomy? The client will:

- ☐ 1. regain the ability to taste and smell food.
- ☐ 2. demonstrate appropriate care of the gastrostomy tube.
- ☐ 3. communicate feelings about body image changes.
- ☐ 4. demonstrate sterile suctioning technique for stoma care.

30. What instruction should the nurse give the client who underwent a laryngectomy and is now going home?

- ☐ 1. Perform mouth care every morning and evening.
- ☐ 2. Provide adequate humidity in the home.
- ☐ 3. Maintain a soft, bland diet.

- ☐ 4. Limit physical activity to shoulder and neck exercises.

The Client with Pneumonia

31. The nurse is caring for a client with bacterial pneumonia. The effectiveness of the client's oxygen therapy can be **best** determined by the:

- ☐ 1. absence of cyanosis.
- ☐ 2. client's respiratory rate.
- ☐ 3. arterial blood gas values.
- ☐ 4. client's level of consciousness.

32. An elderly client admitted with pneumonia and dementia has attempted several times to pull out the IV and Foley catheter. After trying other options, the nurse obtains a prescription for bilateral soft wrist restraints. Which nursing action is **most** appropriate?

- ☐ 1. Perform circulation checks to bilateral upper extremities each shift.
- ☐ 2. Attach the ties of the restraints to the bed frame.
- ☐ 3. Reevaluate the need for restraints and document weekly.
- ☐ 4. Ensure the restraint prescription has been signed by the healthcare provider (HCP) within 72 hours.

33. A 79-year-old client is admitted to the hospital with a diagnosis of bacterial pneumonia. While obtaining the client's health history, the nurse learns that the client has osteoarthritis, follows a vegetarian diet, and is very concerned with cleanliness. Which client information would **most** likely be a predisposing factor for the diagnosis of pneumonia?

- ☐ 1. age
- ☐ 2. osteoarthritis
- ☐ 3. vegetarian diet
- ☐ 4. daily bathing

34. Which findings are significant data to gather from a client who has been diagnosed with pneumonia? Select all that apply.

- ☐ 1. quality of breath sounds
- ☐ 2. presence of bowel sounds
- ☐ 3. occurrence of chest pain

- ☐ 4. amount of peripheral edema
- ☐ 5. color of nail beds

35. A client with bacterial pneumonia is to be started on IV antibiotics. Which diagnostic test must be completed before antibiotic therapy begins?

- ☐ 1. urinalysis
- ☐ 2. sputum culture
- ☐ 3. chest radiograph
- ☐ 4. red blood cell count

36. When caring for the client who is receiving an aminoglycoside antibiotic, the nurse should monitor which laboratory value?

- ☐ 1. serum sodium
- ☐ 2. serum potassium
- ☐ 3. serum creatinine
- ☐ 4. serum calcium

37. The healthcare provider has prescribed penicillin for a client admitted to the hospital for treatment of pneumonia. Prior to administering the first dose of penicillin, the nurse should ask the client:

- ☐ 1. "Do you have a history of seizures?"
- ☐ 2. "Do you have any cardiac history?"
- ☐ 3. "Have you had any recent infections?"
- ☐ 4. "Have you had a previous allergy to penicillin?"

38. A client with pneumonia has a temperature of 102.6°F (39.2°C), is diaphoretic, and has a productive cough. The client is able to ambulate. What should the nurse do?

- ☐ 1. Change the client's position every 4 hours.
- ☐ 2. Use nasotracheal suctioning to clear secretions.
- ☐ 3. Change the bedsheets frequently.
- ☐ 4. Offer the use of a bedpan every 2 hours.

39. Bed rest is prescribed for a client with pneumonia during the acute phase of the illness. The nurse should determine the effectiveness of bed rest by assessing the client's:

- ☐ 1. decreased cellular demand for oxygen.
- ☐ 2. reduced episodes of coughing.
- ☐ 3. diminished pain when breathing deeply.
- ☐ 4. ability to expectorate secretions more easily.

40. A client with pneumonia is experiencing pleuritic chest pain. The nurse should assess the client for:

- ☐ 1. a mild but constant aching in the chest.
- ☐ 2. severe midsternal pain.
- ☐ 3. moderate pain that worsens on inspiration.
- ☐ 4. muscle spasm pain that accompanies coughing.

41. Which nursing action would **most** likely be successful in reducing pleuritic chest pain in a client with pneumonia?

- ☐ 1. Encourage the client to breathe shallowly.
- ☐ 2. Have the client practice abdominal breathing.
- ☐ 3. Offer the client incentive spirometry.
- ☐ 4. Teach the client to splint the rib cage when coughing.

42. The nurse administers two 325-mg aspirin every 4 hours to a client with pneumonia. The nurse should evaluate the outcome of administering the drug by assessing the client for which findings? Select all that apply.

- ☐ 1. decreased pain when breathing
- ☐ 2. prolonged clotting time
- ☐ 3. decreased temperature
- ☐ 4. decreased respiratory rate
- ☐ 5. increased ability to expectorate secretions

43. Which mental status change may occur when a client with pneumonia is first experiencing hypoxia?

- ☐ 1. coma
- ☐ 2. apathy
- ☐ 3. irritability
- ☐ 4. depression

44. The client with pneumonia develops mild constipation, and the nurse

administers docusate sodium as prescribed. This drug works by:

- ☐ 1. softening the stool.
- ☐ 2. lubricating the stool.
- ☐ 3. increasing stool bulk.
- ☐ 4. stimulating peristalsis.

45. Which finding is an expected outcome for an elderly client following treatment for bacterial pneumonia?

- ☐ 1. a respiratory rate of 25 to 30 breaths/min
- ☐ 2. the ability to perform activities of daily living without dyspnea
- ☐ 3. a maximum loss of 5 to 10 lb (2 to 5 kg) of body weight
- ☐ 4. chest pain that is minimized by splinting the rib cage

The Client with Tuberculosis

46. A client newly diagnosed with tuberculosis (TB) is being admitted with the prescription for “isolation precautions for tuberculosis.” The nurse should assign the client to which type of room?

- ☐ 1. a room at the end of the hall for privacy
- ☐ 2. a private room to implement airborne precautions
- ☐ 3. a room near the nurses’ station to ensure confidentiality
- ☐ 4. a room with windows to allow sunlight

47. The nurse is reviewing the history and physical and healthcare provider (HCP) prescriptions on the medical record of a newly admitted client.

History and Physical Tab

Subjective:	19-year-old reports a constant cough for the past "few weeks" with "dark" sputum for the past few days. Has night sweats, 10-lb (4.5-kg) weight loss in the past month, and "always" being tired. He took one Tylenol about an hour prior to arrival.
Objective:	
BP	120/64
HR	84/reg
Resp	26/unlabored/slight wheezing in right lower lobe posteriorly
O ² Sat	92%
Temp	99.9°F (37.7°C) oral
Skin	Warm, slightly diaphoretic
Nonproductive cough at this time	
Assessment:	Possible respiratory infection
Physician prescriptions tab	
	Chest x-ray
	Sputum specimen
	Oxygen at 2 L per nasal cannula

The nurse should **first**:

- ☐ 1. initiate airborne precautions.
- ☐ 2. apply oxygen at 2 L per nasal cannula.
- ☐ 3. collect a sputum sample.
- ☐ 4. reassess vital signs.

48. A client is receiving streptomycin in the treatment regimen of tuberculosis. The nurse should assess for:

- ☐ 1. decreased serum creatinine.
- ☐ 2. difficulty swallowing.
- ☐ 3. hearing loss.
- ☐ 4. IV infiltration.

49. The nurse is reconciling the prescriptions for a client diagnosed recently with pulmonary tuberculosis who is being admitted to the hospital for a total hip replacement. (See medication prescription sheet.) The client asks if it is necessary to take all of these medications while in the hospital. The nurse should:

Medication Prescription

isoniazid (INH), 300 mg PO daily
Rifampin (Rifadin), 600 mg PO daily
Pyridoxine (vitamin B₆), 10 mg PO daily
ethambutol, 400 mg PO daily
pyrazinamide, 1.5 g PO daily.

Dr. Smith 6-29-15

- ☐ 1. request that the healthcare provider (HCP) review the prescriptions for a duplication between isoniazid and ethambutol.

- ☐ 2. inform the client that all drugs will be discontinued until the client can eat solid foods.
- ☐ 3. ask the pharmacist to check for drug interactions between the rifampin and isoniazid.
- ☐ 4. tell the client that it is important to continue to take the medications because the combination of drugs prevents bacterial resistance.

50. The client with tuberculosis is to be discharged home with nursing follow-up. Which aspect of nursing care will have the **highest priority**?

- ☐ 1. offering the client emotional support
- ☐ 2. teaching the client about the disease and its treatment
- ☐ 3. coordinating various agency services
- ☐ 4. assessing the client's environment for sanitation

51. The nurse is reading the results of a tuberculin skin test (see figure). The nurse should interpret the results as:

- ☐ 1. negative.
- ☐ 2. needing to be repeated.
- ☐ 3. positive.
- ☐ 4. false.

52. Which technique for administering the Mantoux test is correct?

- ☐ 1. Hold the needle and syringe almost parallel to the client's skin.
- ☐ 2. Pinch the skin when inserting the needle.
- ☐ 3. Aspirate before injecting the medication.
- ☐ 4. Massage the site after injecting the medication.

53. A client had a Mantoux test result of an 8-mm induration. The test is considered positive when the client:

- ☐ 1. lives in a long-term care facility.
- ☐ 2. has no known risk factors.

- ☐ 3. is immunocompromised.
- ☐ 4. works as a healthcare provider (HCP) in a hospital.

54. Which family member exposed to tuberculosis would be at **highest** risk for contracting the disease?

- ☐ 1. 45-year-old mother
- ☐ 2. 17-year-old daughter
- ☐ 3. 8-year-old son
- ☐ 4. 76-year-old grandmother

55. The nurse is teaching a client who has been diagnosed with tuberculosis how to avoid spreading the disease to family members. Which statements indicate that the client has understood the nurse's instructions? Select all that apply.

- ☐ 1. "I will need to dispose of my old clothing when I return home."
- ☐ 2. "I should always cover my mouth and nose when sneezing."
- ☐ 3. "It is important that I isolate myself from family when possible."
- ☐ 4. "I should use paper tissues to cough in and dispose of them promptly."
- ☐ 5. "I will avoid crowds."

56. A client has a positive reaction to the Mantoux test. The nurse interprets this reaction to mean that the client has:

- ☐ 1. active tuberculosis.
- ☐ 2. been exposed to *Mycobacterium tuberculosis*.
- ☐ 3. developed a resistance to tubercle bacilli.
- ☐ 4. developed passive immunity to tuberculosis.

57. A client with tuberculosis is taking isoniazid (INH). To help prevent development of peripheral neuropathies, the nurse should instruct the client to:

- ☐ 1. adhere to a low-cholesterol diet.
- ☐ 2. supplement the diet with pyridoxine (vitamin B₆).
- ☐ 3. get extra rest.
- ☐ 4. avoid excessive sun exposure.

58. The nurse should caution sexually active female clients taking

isoniazid (INH) that the drug:

- ☐ 1. increases the risk of vaginal infection.
- ☐ 2. has mutagenic effects on ova.
- ☐ 3. decreases the effectiveness of hormonal contraceptives.
- ☐ 4. inhibits ovulation.

59. Clients who have had active tuberculosis are at risk for recurrence.

Which condition increases that risk?

- ☐ 1. cool and damp weather
- ☐ 2. active exercise and exertion
- ☐ 3. physical and emotional stress
- ☐ 4. rest and inactivity

60. In which areas of the United States and Canada is the incidence of tuberculosis **highest**?

- ☐ 1. rural farming areas
- ☐ 2. inner-city areas
- ☐ 3. areas where clean water standards are low
- ☐ 4. suburban areas with significant industrial pollution

61. The nurse should include which instruction when developing a teaching plan for a client who is receiving isoniazid and rifampin for treatment of tuberculosis?

- ☐ 1. Take the medication with antacids.
- ☐ 2. Double the dosage if a drug dose is missed.
- ☐ 3. Increase intake of dairy products.
- ☐ 4. Avoid alcohol.

62. A client who has been diagnosed with tuberculosis has been placed on drug therapy. The medication regimen includes rifampin. Which instruction should the nurse give the client about potential adverse effects of rifampin? Select all that apply.

- ☐ 1. Have eye examinations every 6 months.
- ☐ 2. Maintain follow-up monitoring of liver enzymes.
- ☐ 3. Decrease protein intake in the diet.

- ☐ 4. Avoid alcohol intake.
- ☐ 5. The urine may have an orange color.

63. The nurse is providing follow-up care to a client with tuberculosis who does not regularly take the prescribed medication. Which nursing action would be **most** appropriate for this client?

- ☐ 1. Ask the client's spouse to supervise the daily administration of the medications.
- ☐ 2. Visit the client weekly to verify compliance with taking the medication.
- ☐ 3. Notify the healthcare provider (HCP) of the client's noncompliance, and request a different prescription.
- ☐ 4. Remind the client that tuberculosis can be fatal if it is not treated promptly.

The Client with Chronic Obstructive Pulmonary Disease

64. A client with newly diagnosed chronic obstructive disease is to be discharged home with oxygen per nasal prongs. Which teaching points should the nurse include in this client's discharge plan? Select all that apply.

- ☐ 1. Apply Vaseline or petroleum jelly on lips and nose to prevent dryness and irritation.
- ☐ 2. Avoid areas where people are smoking cigarettes or cigars.
- ☐ 3. Increase oxygen flow at night during hours of sleep.
- ☐ 4. Place gauze between the ears and oxygen tubing to prevent skin irritation.
- ☐ 5. Request a large, pressurized oxygen tank for use during car travel.
- ☐ 6. Avoid use of a microwave oven when using oxygen.

65. A nurse is reviewing the medications used by a client who has chronic bronchitis and a history of high blood pressure and prostate enlargement. The nurse should verify that the client understands how to use which medications? Select all that apply.

- ☐ 1. albuterol and ipratropium by metered-dose inhaler
- ☐ 2. guaifenesin with dextromethorphan liquid

- ☐ 3. generic pseudoephedrine tablets
- ☐ 4. lisinopril tablets
- ☐ 5. tamsulosin

66. Which information should the nurse include in a teaching plan for the client newly diagnosed with chronic obstructive pulmonary disease? Select all that apply.

- ☐ 1. Pulmonary rehabilitation programs offer very little benefit.
- ☐ 2. Pneumococcal vaccination is contraindicated for clients with lung disease.
- ☐ 3. High humidity may increase your work of breathing.
- ☐ 4. A bronchodilator with metered-dose inhaler should be readily available.
- ☐ 5. Smoking cessation is important to slow or stop disease progression.

67. A nurse is assessing a client with chronic emphysema. Which finding requires immediate intervention?

- ☐ 1. using pursed-lip breathing and prolonged expiration
- ☐ 2. circumoral cyanosis
- ☐ 3. crackles auscultated posteriorly halfway up the left lung
- ☐ 4. appearance of a “barrel chest”

68. The nurse is assessing a client with COPD. Which requires immediate intervention?

- ☐ 1. distant heart sounds
- ☐ 2. diminished lung sounds
- ☐ 3. inability to speak
- ☐ 4. pursed-lip breathing

69. The nurse is instructing a client with chronic obstructive pulmonary disease (COPD) how to do pursed-lip breathing. In which order from first to last should the nurse explain the steps to the client? All options must be used.

- 1. “Breathe in normally through your nose for two counts (while counting to yourself, one, two).”

2. “Relax your neck and shoulder muscles.”

3. “Pucker your lips as if you were going to whistle.”

4. “Breathe out slowly through pursed lips for four counts (while counting to yourself, one, two, three, four).”

70. The nurse reviews an arterial blood gas report for a client with chronic obstructive pulmonary disease (COPD). The results are as follows: pH 7.35; Pco₂ 62 (8.25 kPa); Po₂ 70 (9.31 kPa); HCO₃ 34 mEq/L (34 mmol/L). The nurse should **first**:

- ☐ 1. apply a 100% nonrebreather mask.
- ☐ 2. assess the vital signs.
- ☐ 3. reposition the client.
- ☐ 4. prepare for intubation.

71. When developing a discharge plan to manage the care of a client with chronic obstructive pulmonary disease (COPD), the nurse should advise the client to expect to:

- ☐ 1. develop respiratory infections easily.
- ☐ 2. maintain current status.
- ☐ 3. require less supplemental oxygen.
- ☐ 4. show permanent improvement.

72. The client with chronic obstructive pulmonary disease (COPD) is taking theophylline. The nurse should instruct the client to report which signs

of theophylline toxicity? Select all that apply.

- ☐ 1. nausea
- ☐ 2. vomiting
- ☐ 3. seizures
- ☐ 4. insomnia
- ☐ 5. vision changes

73. Which statement indicates that the client with chronic obstructive pulmonary disease (COPD) who has been discharged to home understands the care plan?

- ☐ 1. The client will avoid direct contact with family and friends.
- ☐ 2. The client states actions to reduce pain.
- ☐ 3. The client will use oxygen via a nasal cannula at 5 L/min.
- ☐ 4. The client agrees to call the healthcare provider (HCP) if dyspnea on exertion increases.

74. When instructing clients on how to decrease the risk of developing chronic obstructive pulmonary disease (COPD), the nurse should emphasize which instruction?

- ☐ 1. Participate regularly in aerobic exercises.
- ☐ 2. Maintain a high-protein diet.
- ☐ 3. Avoid exposure to people with known respiratory infections.
- ☐ 4. Abstain from cigarette smoking.

75. Which is an expected outcome of pursed-lip breathing for clients with emphysema?

- ☐ 1. to promote oxygen intake
- ☐ 2. to strengthen the diaphragm
- ☐ 3. to strengthen the intercostal muscles
- ☐ 4. to promote carbon dioxide elimination

76. Which is a **priority** goal for the client with chronic obstructive pulmonary disease (COPD)?

- ☐ 1. maintaining functional ability
- ☐ 2. minimizing chest pain

- ☐ 3. increasing carbon dioxide levels in the blood
- ☐ 4. treating infectious agents

77. When teaching a client with chronic obstructive pulmonary disease to conserve energy, the nurse should teach the client to lift objects:

- ☐ 1. while inhaling through an open mouth.
- ☐ 2. while exhaling through pursed lips.
- ☐ 3. after exhaling but before inhaling.
- ☐ 4. while taking a deep breath and holding it.

78. The nurse is teaching a client with chronic obstructive pulmonary disease (COPD) to assess for signs and symptoms of right-sided heart failure. Which signs and symptoms should be included in the teaching plan?

- ☐ 1. clubbing of nail beds
- ☐ 2. hypertension
- ☐ 3. peripheral edema
- ☐ 4. increased appetite

79. The nurse assesses the respiratory status of a client who is experiencing an exacerbation of chronic obstructive pulmonary disease (COPD) secondary to an upper respiratory tract infection. Which findings are expected?

- ☐ 1. normal breath sounds
- ☐ 2. prolonged inspiration
- ☐ 3. normal chest movement
- ☐ 4. coarse crackles and rhonchi

80. A client with chronic obstructive pulmonary disease (COPD) is experiencing dyspnea and has a low PaO₂ level. The nurse plans to administer oxygen as prescribed. Which statement is true concerning oxygen administration to a client with COPD?

- ☐ 1. High oxygen concentrations will cause coughing and dyspnea.
- ☐ 2. High oxygen concentrations may inhibit the hypoxic stimulus to breathe.
- ☐ 3. Increased oxygen use will cause the client to become dependent on the oxygen.

- ☐ 4. Administration of oxygen is contraindicated in clients who are using bronchodilators.

81. Which diet would be **most** appropriate for a client with chronic obstructive pulmonary disease (COPD)?

- ☐ 1. low-fat, low-cholesterol diet
- ☐ 2. bland, soft diet
- ☐ 3. low-sodium diet
- ☐ 4. high-calorie, high-protein diet

82. The nurse administers theophylline to a client. When evaluating the effectiveness of this medication, the nurse should assess the client for:

- ☐ 1. suppression of the client's respiratory infection
- ☐ 2. decrease in bronchial secretions
- ☐ 3. less difficulty breathing
- ☐ 4. thinning of tenacious, purulent sputum

83. The nurse is planning to teach a client with chronic obstructive pulmonary disease how to cough effectively. Which instruction should be included?

- ☐ 1. Take a deep abdominal breath, bend forward, and cough three or four times on exhalation.
- ☐ 2. Lie flat on the back, splint the thorax, take two deep breaths, and cough.
- ☐ 3. Take several rapid, shallow breaths, and then cough forcefully.
- ☐ 4. Assume a side-lying position, extend the arm over the head, and alternate deep breathing with coughing.

The Client with Asthma

84. The nurse observes a client using a metered-dose inhaler (MDI) to aid in management of asthma. Which actions indicate that the client needs further instruction? Select all that apply.

- ☐ 1. shakes the MDI before using
- ☐ 2. exhales before starting to use the MDI
- ☐ 3. inspires rapidly when dispensing the medication from the MDI

- ☐ 4. holds the breath for 3 seconds after inhaling with the MDI
- ☐ 5. cleans the inhaler and canister in soapy water before using again in rapid succession

85. A client with a history of asthma is admitted to the emergency department. The nurse notes that the client is dyspneic, with a respiratory rate of 35 breaths/min, nasal flaring, and use of accessory muscles. Auscultation of the lung fields reveals greatly diminished breath sounds. What should the nurse do **first**?

- ☐ 1. Initiate oxygen therapy as prescribed, and reassess the client in 10 minutes.
- ☐ 2. Draw blood for an arterial blood gas.
- ☐ 3. Encourage the client to relax and breathe slowly through the mouth.
- ☐ 4. Administer bronchodilators as prescribed.

86. A client is experiencing an acute asthmatic attack. Prior to treatment with levalbuterol, respirations were 40 breaths/min, pulse 132 beats/min, oxygen saturation 86% on room air, and with audible wheezing. Which findings indicate achievement of the desired outcome of asthma treatment?

- ☐ 1. decreased peak expiratory flow (PEF) rate
- ☐ 2. wheezing inaudible with diminished breath sounds
- ☐ 3. pulse 96 bpm and SpO₂ 92% on room air
- ☐ 4. inspiratory cycle twice as long as the expiratory cycle

87. For a client with asthma, the healthcare provider (HCP) prescribes albuterol, two puffs twice a day via MDI, and beclomethasone, two puffs twice a day via MDI. The nurse should instruct the client to administer:

- ☐ 1. medications 1 hour apart, two times a day.
- ☐ 2. albuterol first and follow with beclomethasone two times a day.
- ☐ 3. albuterol on awakening and alternate the medications every 4 hours.
- ☐ 4. beclomethasone inhaler first and follow with albuterol.

88. A client experiencing a severe asthma attack has the following arterial blood gas results: pH 7.33; Pco₂ 48 mm Hg (6.4 kPa); Po₂ 58 mm Hg (7.7 kPa); HCO₃ 26 mEq/L (26 mmol/L). Which prescriptions should the nurse implement **first**?

- ☐ 1. albuterol nebulizer
- ☐ 2. chest x-ray
- ☐ 3. ipratropium inhaler
- ☐ 4. sputum culture

89. A client with acute asthma is prescribed short-term corticosteroid therapy. Which is the expected outcome for the use of steroids in clients with asthma?

- ☐ 1. promote bronchodilation
- ☐ 2. act as an expectorant
- ☐ 3. have an anti-inflammatory effect
- ☐ 4. prevent development of respiratory infections

90. The nurse is teaching the client how to use a metered-dose inhaler (MDI) to administer a corticosteroid. Which observation indicates that the client is using the MDI correctly? Select all that apply.

- ☐ 1. The inhaler is held upright.
- ☐ 2. The head is tilted down while inhaling the medicine.
- ☐ 3. The client waits 5 minutes between puffs.
- ☐ 4. The client rinses the mouth with water following administration.
- ☐ 5. The client lies supine for 15 minutes following administration.

91. A client is prescribed metaproterenol via a metered-dose inhaler, two puffs every 4 hours. The nurse instructs the client to report which adverse effect?

- ☐ 1. irregular heartbeat
- ☐ 2. constipation
- ☐ 3. pedal edema
- ☐ 4. decreased pulse rate

92. A client who has been taking flunisolide nasal spray, two inhalations a day, for treatment of asthma has painful, white patches in the mouth. What should the nurse tell the client?

- ☐ 1. "This is an anticipated adverse effect of your medication. It should go away in a couple of weeks."
- ☐ 2. "You are using your inhaler too much, and it has irritated your mouth."

- ☐ 3. “You have developed a fungal infection from your medication. It will need to be treated with an antifungal agent.”
- ☐ 4. “Be sure to brush your teeth and floss daily. Good oral hygiene will treat this problem.”

93. A nurse is teaching a client to use a metered-dose inhaler (MDI) to administer bronchodilator medication. Indicate the correct order of the steps from first to last the client should take to use the MDI appropriately. All options must be used.

1. Shake the inhaler immediately before use.

2. Hold the breath for 10 seconds, and then exhale.

3. Activate the MDI on inhalation.

4. Breathe out through the mouth.

94. What is an expected outcome for an adult client with well-controlled asthma?

- ☐ 1. Chest x-ray demonstrates minimal hyperinflation.
- ☐ 2. Temperature remains lower than 100°F (37.8°C).
- ☐ 3. Arterial blood gas analysis demonstrates a decrease in PaO₂.
- ☐ 4. Breath sounds are clear.

95. Which instruction should the nurse include in the discharge teaching

plan for a client with asthma?

- ☐ 1. Incorporate physical exercise as tolerated into the daily routine.
- ☐ 2. Monitor peak flow numbers after meals and at bedtime.
- ☐ 3. Eliminate stressors in the work and home environment.
- ☐ 4. Use sedatives to ensure uninterrupted sleep at night.

96. The nurse should teach the client with asthma to avoid which of the **most** common precipitating factors of an acute asthma attack?

- ☐ 1. occupational exposure to toxins
- ☐ 2. Valsalva maneuver
- ☐ 3. exposure to cigarette smoke
- ☐ 4. exercising in cold temperatures

97. When assessing a client with asthma, which findings would **most** likely indicate the presence of a respiratory infection?

- ☐ 1. cough productive of yellow sputum
- ☐ 2. bilateral expiratory wheezing
- ☐ 3. chest tightness
- ☐ 4. respiratory rate of 30 breaths/min

98. The nurse is caring for a client who has asthma. The nurse should conduct a focused assessment to detect:

- ☐ 1. increased forced expiratory volume.
- ☐ 2. normal breath sounds.
- ☐ 3. inspiratory and expiratory wheezing.
- ☐ 4. morning headaches.

The Client with Lung Cancer

99. The nurse has assisted the healthcare provider (HCP) at the bedside with insertion of a left subclavian, triple lumen catheter in a client admitted with lung cancer. Suddenly, the client becomes restless and tachypneic. The nurse should:

- ☐ 1. assess breath sounds.
- ☐ 2. remove the catheter.

- ☐ 3. insert a peripheral IV.
- ☐ 4. reposition the client.

100. A recently extubated client has shortness of breath. The nurse reports the client's discomfort and the results of the recently prescribed arterial blood gas analysis to the healthcare provider (HCP). After reviewing the report of the complete blood count (see report), the nurse should also report which results to the HCP?

- ☐ 1. PT
- ☐ 2. hemoglobin and hematocrit
- ☐ 3. monocytes
- ☐ 4. platelets

Laboratory Values

Complete Blood Count (CBC) with Differential				
Test Results	Current Results	Previous Results	Units	Reference Interval
White Blood Count (WBC)	3.6	3.4	$\times 10^3/\text{mm}^3$	5.0–10.0
Red Blood Count (RBC)	3.20	3.6	$\times 10^6/\text{mm}^3$	4.1–5.3
Hemoglobin (Hgb)	9.6	10.5	g/dL	12.0–18.0

101. A female client diagnosed with lung cancer is to have a left lower lobectomy. What **increases** the client's risk of developing postoperative pulmonary complications?

- ☐ 1. Height is 5 feet, 7 inches (170.2 cm) and weight is 110 lb (49.9 kg).
- ☐ 2. The client tends to keep her real feelings to herself.
- ☐ 3. She ambulates and can climb one flight of stairs without dyspnea.
- ☐ 4. The client is 58 years of age.

102. The nurse in the perioperative area is preparing a client for surgery and notices that the client looks sad. The client says, "I am scared of having cancer. It is so horrible, and I brought it on myself. I should have quit smoking years ago." What would be the nurse's **best** response to the client?

- ☐ 1. "It is okay to be scared. What is it about cancer that you are afraid of?"
- ☐ 2. "It is normal to be scared. I would be, too. We will help you through it."

- ☐ 3. “Do not be so hard on yourself. You do not know if your smoking caused the cancer.”
- ☐ 4. “Do you feel guilty because you smoked?”

103. A client who underwent a left lower lobectomy has been out of surgery for 48 hours. The client is receiving morphine sulfate via a patient-controlled analgesia (PCA) system and reports having pain in the left thorax that worsens when coughing. After checking the PCA system, the nurse should **next**:

- ☐ 1. let the client rest, so that the client is not stimulated to cough.
- ☐ 2. encourage the client to take deep breaths to help control the pain.
- ☐ 3. reassure the client that the machine is working and will administer medication to relieve the pain.
- ☐ 4. obtain a more detailed assessment of the client’s pain using a pain scale.

104. Which factor is a **priority** to evaluate when completing discharge planning for a client who has had a lobectomy for treatment of lung cancer?

- ☐ 1. the support available to assist the client at home
- ☐ 2. the distance the client lives from the hospital
- ☐ 3. the client’s ability to do home blood pressure monitoring
- ☐ 4. the client’s knowledge of the causes of lung cancer

105. What is an instruction the nurse can give to help people prevent lung cancer?

- ☐ 1. Encourage cigarette smokers to have yearly chest radiographs.
- ☐ 2. Instruct people about techniques for smoking cessation.
- ☐ 3. Recommend that people have their houses and apartments checked for asbestos leakage.
- ☐ 4. Encourage people to install central air filters in their homes.

106. After a thoracotomy, the nurse instructs the client to perform deep-breathing exercises. What is an expected outcome of these exercises?

- ☐ 1. The elevated diaphragm enlarges the thorax and increases the lung surface available for gas exchange.
- ☐ 2. There is increased blood flow to the lungs to allow them to recover

from the trauma of surgery.

- ☐ **3.** The rate of airflow to the remaining lobe is controlled so that it will not become hyperinflated.
- ☐ **4.** The alveoli expand and increase the lung surface available for ventilation.

107. Following a thoracotomy, the client has pain of 9 on a 10-point scale. Thirty minutes after administering the highest dose of the prescribed pain medication, the nurse should:

- ☐ **1.** reposition the client.
- ☐ **2.** reassess the client.
- ☐ **3.** reassure the client.
- ☐ **4.** readjust the pain medication dosage as needed.

108. While assessing a thoracotomy incisional area from which a chest tube exits, the nurse feels a crackling sensation under the fingertips along the entire incision. What should the nurse do **next**?

- ☐ **1.** Lower the head of the bed, and call the healthcare provider (HCP).
- ☐ **2.** Prepare an aspiration tray.
- ☐ **3.** Mark the area with a skin pencil at the outer periphery of the crackling.
- ☐ **4.** Turn off the suction of the chest drainage system.

109. When teaching a client to deep breathe effectively after a lobectomy, what should the nurse instruct the client to do?

- ☐ **1.** Contract the abdominal muscles; take a slow, deep breath through the nose; hold it for 3 to 5 seconds; and then exhale.
- ☐ **2.** Contract the abdominal muscles, take a deep breath through the mouth, and exhale slowly as if trying to blow out a candle.
- ☐ **3.** Relax the abdominal muscles; take a slow, deep breath through the nose; and hold it for 3 to 5 seconds.
- ☐ **4.** Relax the abdominal muscles, take a deep breath through the mouth, and exhale slowly over 10 seconds.

110. Which instruction should the nurse give the client who has undergone chest surgery to prevent shoulder ankylosis?

- ☐ **1.** Turn from side to side.

- ☐ 2. Raise and lower the head.
- ☐ 3. Raise the arm on the affected side over the head.
- ☐ 4. Flex and extend the elbow on the affected side.

111. When caring for a client with a chest tube and water seal drainage system, the nurse should:

- ☐ 1. verify that the air vent on the water seal drainage system is capped when the suction is off.
- ☐ 2. strip the chest drainage tubes at least every 4 hours if excessive bleeding occurs.
- ☐ 3. ensure that the chest tube is clamped when moving the client out of the bed.
- ☐ 4. make sure that the drainage apparatus is always below the client's chest level.

112. A client has a chest tube attached to a water seal drainage system, and the nurse notes that the fluid in the chest tube and in the water seal column has stopped fluctuating. The nurse should determine that:

- ☐ 1. the lung has fully expanded.
- ☐ 2. the lung has collapsed.
- ☐ 3. the chest tube is in the pleural space.
- ☐ 4. the mediastinal space has decreased.

113. The nurse observes a constant gentle bubbling in the water seal column of a water seal chest drainage system. The nurse should:

- ☐ 1. continue monitoring as usual; this is expected.
- ☐ 2. check the connectors between the chest and drainage tubes and where the drainage tube enters chest drainage system.
- ☐ 3. decrease the suction and continue observing the system for changes in bubbling during the next several hours.
- ☐ 4. notify the healthcare provider (HCP).

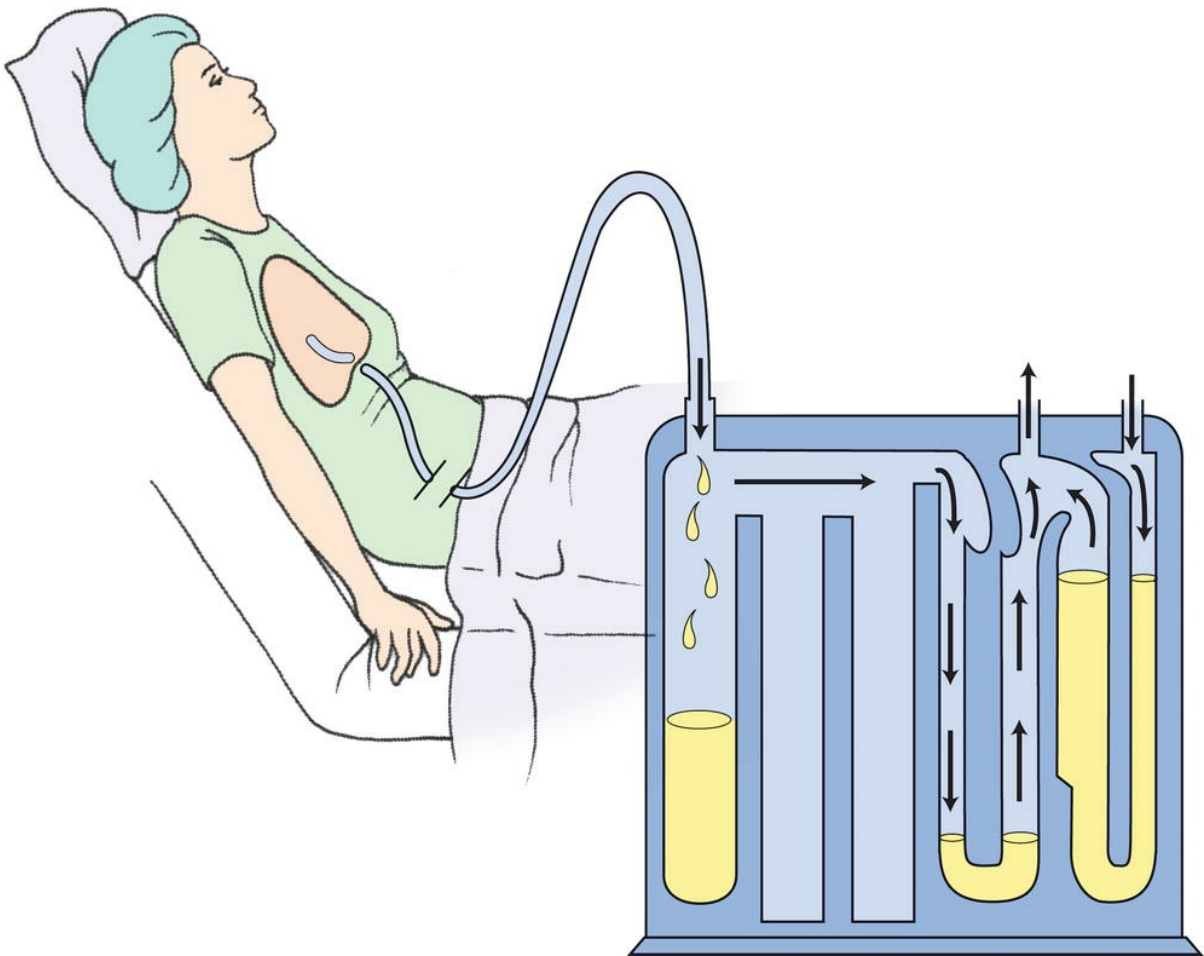

114. A client who underwent a lobectomy and has a water seal chest drainage system is breathing with a little more effort and at a faster rate than 1 hour ago. The client's pulse rate is also increased. The nurse should:

- ☐ 1. check the tubing to ensure that the client is not lying on it or kinking it.

- ☐ 2. increase the suction.
- ☐ 3. lower the drainage bottles 2 to 3 feet (61 to 91.4 cm) below the level of the client's chest.
- ☐ 4. ensure that the chest tube has two clamps on it to prevent air leaks.

115. The nurse is assessing a client who has a chest tube connected to a water seal chest tube drainage system. According to the illustration shown, what should the nurse do?

- ☐ 1. Clamp the chest tube near the insertion site to prevent air from entering the pleural cavity.
- ☐ 2. Notify the healthcare provider (HCP) of the amount of chest tube drainage.
- ☐ 3. Add water to maintain the water seal.
- ☐ 4. Lower the drainage system to maintain gravity flow.

116. What should be readily available at the bedside of a client with a

chest tube in place?

- ☐ 1. a tracheostomy tray
- ☐ 2. another sterile chest tube
- ☐ 3. a bottle of sterile water
- ☐ 4. a spirometer

117. The nurse is preparing to assist with the removal of a chest tube. Which dressing is appropriate at the site from which the chest tube is removed?

- ☐ 1. adhesive strips
- ☐ 2. petrolatum gauze
- ☐ 3. dry 4 × 4 gauze
- ☐ 4. no dressing is necessary

The Client with Chest Trauma

118. A nurse should interpret which finding as an early sign of a tension pneumothorax in a client with chest trauma?

- ☐ 1. diminished bilateral breath sounds
- ☐ 2. muffled heart sounds
- ☐ 3. respiratory distress
- ☐ 4. tracheal deviation

119. A nurse is to administer 10 mg of morphine sulfate to a client with three fractured ribs. The available concentration for this drug is 15 mg/mL. How many milliliters should the nurse administer? Round to one decimal point. mL.

120. A young adult is admitted to the emergency department after an automobile accident. The client has severe pain in the right chest from contact with the steering wheel. What should the nurse do **first**?

- ☐ 1. Reduce the client's anxiety.
- ☐ 2. Maintain adequate oxygenation.
- ☐ 3. Decrease chest pain.
- ☐ 4. Maintain adequate circulating volume.

121. A client with rib fractures and a pneumothorax has a chest tube inserted that is connected to a water seal chest tube drainage system. The nurse notes that the fluid in the water seal column is fluctuating with each breath that the client takes. What is the significance of this fluctuation?

- ☐ 1. An obstruction is present in the chest tube.
- ☐ 2. The client is developing subcutaneous emphysema.
- ☐ 3. The chest tube system is functioning properly.
- ☐ 4. There is a leak in the chest tube system.

122. Which finding would suggest pneumothorax in a trauma victim?

- ☐ 1. pronounced crackles
- ☐ 2. inspiratory wheezing
- ☐ 3. dullness on percussion
- ☐ 4. absent breath sounds

123. For a client with rib fractures and a pneumothorax, the healthcare provider (HCP) prescribes morphine sulfate, 1 to 2 mg/h, given IV as needed for pain. The nursing care goal is to provide adequate pain control so that the client can breathe effectively. Which finding indicates the goal has been met?

- ☐ 1. pain rating of 0 to 2 on a scale of 0 to 10 by the client
- ☐ 2. decreased client anxiety
- ☐ 3. respiratory rate of 26 breaths/min
- ☐ 4. PaO₂ of 70 mm Hg (9.31 kPa)

124. A client undergoes surgery to repair lung injuries. Postoperative prescriptions include the transfusion of one unit of packed red blood cells at a rate of 60 mL/h. How long will this transfusion take to infuse?

- ☐ 1. 2 hours
- ☐ 2. 4 hours
- ☐ 3. 6 hours
- ☐ 4. 8 hours

125. The primary reason for infusing blood at a rate of 60 mL/h is to help prevent:

- ☐ 1. emboli formation.

- ☐ 2. fluid volume overload.
- ☐ 3. red blood cell hemolysis.
- ☐ 4. allergic reaction.

126. A client has been in an automobile accident, and the nurse is assessing the client for possible pneumothorax. The nurse should assess the client for:

- ☐ 1. sudden, sharp chest pain.
- ☐ 2. wheezing breath sounds over affected side.
- ☐ 3. hemoptysis.
- ☐ 4. cyanosis.

127. The healthcare provider (HCP) has inserted a chest tube in a client with a pneumothorax. The nurse should evaluate the effectiveness of the chest tube:

- ☐ 1. for administration of oxygen.
- ☐ 2. to promote formation of lung scar tissue.
- ☐ 3. to insert antibiotics into the pleural space.
- ☐ 4. to remove air and fluid.

128. The nurse is preparing the client diagnosed with pleural effusion for a left-sided thoracentesis. The x-ray shows fluid in the pleural cavity. During the preparation for the procedure, the client asks where the healthcare provider (HCP) will “put the needle.” Select the appropriate site from the diagram.

129. A client is undergoing a thoracentesis. What should the nurse monitor the client for during and immediately after the procedure? Select all that apply.

- ☐ 1. pneumothorax
- ☐ 2. subcutaneous emphysema
- ☐ 3. tension pneumothorax
- ☐ 4. pulmonary edema
- ☐ 5. infection

130. When assessing a client with chest trauma, the nurse notes that the

client is taking small breaths at first, then bigger breaths, and then a couple of small breaths, then 10 to 20 seconds of no breaths. The nurse should record the breathing pattern as:

- ☐ 1. Cheyne-Stokes respiration.
- ☐ 2. hyperventilation.
- ☐ 3. obstructive sleep apnea.
- ☐ 4. Biot's respiration.

The Client with Acute Respiratory Distress Syndrome

131. The nurse has placed the intubated client with acute respiratory distress syndrome (ARDS) in prone position for 30 minutes. Which factors would require the nurse to discontinue prone positioning and return the client to the supine position? Select all that apply.

- ☐ 1. The family is coming in to visit.
- ☐ 2. The client has increased secretions requiring frequent suctioning.
- ☐ 3. The SpO₂ and Po₂ have decreased.
- ☐ 4. The client is tachycardic with drop in blood pressure.
- ☐ 5. The face has increased skin breakdown and edema.

132. To improve the oxygenation of a client with acute respiratory distress syndrome (ARDS) who is receiving mechanical ventilation, the nurse should place the client in which position?

- ☐ 1. supine
- ☐ 2. semi-Fowler's
- ☐ 3. lateral side
- ☐ 4. prone

133. A client with acute respiratory distress syndrome (ARDS) has fine crackles at lung bases, and the respirations are shallow at a rate of 28 breaths/min. The client is restless and anxious. In addition to monitoring the arterial blood gas results, what should the nurse do? Select all that apply.

- ☐ 1. Monitor serum creatinine and blood urea nitrogen levels.
- ☐ 2. Administer a sedative.
- ☐ 3. Keep the head of the bed flat.

- ☐ 4. Administer humidified oxygen.
- ☐ 5. Auscultate the lungs.

134. Which nursing interventions would be **most** likely to prevent the development of acute respiratory distress syndrome (ARDS)?

- ☐ 1. teaching cigarette smoking cessation
- ☐ 2. maintaining adequate serum potassium levels
- ☐ 3. monitoring clients for signs of hypercapnia
- ☐ 4. replacing fluids adequately during hypovolemic states

135. The nurse interprets which finding as an early sign of acute respiratory distress syndrome (ARDS) in a client at risk?

- ☐ 1. elevated carbon dioxide level
- ☐ 2. hypoxia not responsive to oxygen therapy
- ☐ 3. metabolic acidosis
- ☐ 4. severe, unexplained electrolyte imbalance

136. A client with acute respiratory distress syndrome (ARDS) is showing signs of increased dyspnea. The nurse reviews a report of blood gas values that recently arrived (see report).

Laboratory Results

Blood Chemistry	Result
pH	7.35
PaCO ₂	25 mm Hg (3.3 kPa)
Hco ₃ ⁻	22 mEq/L (22 mmol/L)
PaO ₂	95 mm Hg (12.6 kPa)

Which finding is abnormal?

- ☐ 1. pH

- ☐ 2. PaCO_2
- ☐ 3. HCO_3
- ☐ 4. PaO_2

137. A client with acute respiratory distress syndrome (ARDS) is on a ventilator. The client's peak inspiratory pressures and spontaneous respiratory rate are increasing, and the Po_2 is not improving. Using the SBAR (Situation-Background-Assessment-Recommendation) technique for communication, the nurse calls the healthcare provider (HCP) with the recommendation for:

- ☐ 1. initiating IV sedation.
- ☐ 2. starting a high-protein diet.
- ☐ 3. providing pain medication.
- ☐ 4. increasing the ventilator rate.

138. A client, diagnosed with acute pancreatitis 5 days ago, is experiencing respiratory distress. Which finding should the nurse report to the healthcare provider (HCP)?

- ☐ 1. arterial oxygen level of 46 mm Hg (6.1 kPa)
- ☐ 2. respirations of 12 breaths/min
- ☐ 3. lack of adventitious lung sounds
- ☐ 4. oxygen saturation of 96% on room air

139. A client has the following arterial blood gas values: pH, 7.52; PaO_2 , 50 mm Hg (6.7 kPa); PaCO_2 , 28 mm Hg (3.72 kPa); HCO_3^- 24 mEq/L (24 mmol/L). Based upon the client's PaO_2 , which conclusion would be accurate?

- ☐ 1. The client is severely hypoxic.
- ☐ 2. The oxygen level is low but poses no risk for the client.
- ☐ 3. The client's PaO_2 level is within normal range.
- ☐ 4. The client requires oxygen therapy with very low oxygen concentrations.

140. Which action should the nurse anticipate in a client who has been

diagnosed with acute respiratory distress syndrome (ARDS)?

- ☐ 1. tracheostomy
- ☐ 2. use of a nasal cannula
- ☐ 3. mechanical ventilation
- ☐ 4. insertion of a chest tube

141. Which condition can place a client at risk for acute respiratory distress syndrome (ARDS)?

- ☐ 1. septic shock
- ☐ 2. chronic obstructive pulmonary disease
- ☐ 3. asthma
- ☐ 4. heart failure

142. Which assessment is **most** appropriate for determining the correct placement of an endotracheal tube in a mechanically ventilated client?

- ☐ 1. assessing the client's skin color
- ☐ 2. monitoring the respiratory rate
- ☐ 3. verifying the amount of cuff inflation
- ☐ 4. auscultating breath sounds bilaterally

143. To promote effective airway clearance in a client with acute respiratory distress, what should the nurse do?

- ☐ 1. Administer oxygen every 2 hours.
- ☐ 2. Turn the client every 4 hours.
- ☐ 3. Administer sedatives to promote rest.
- ☐ 4. Suction if cough is ineffective.

144. Which complication is associated with mechanical ventilation?

- ☐ 1. gastrointestinal hemorrhage
- ☐ 2. immunosuppression
- ☐ 3. increased cardiac output
- ☐ 4. pulmonary emboli

Managing Care, Quality, and Safety of Clients with Respiratory Health Problems

145. The nurse has received a change of shift report on clients. Which client should the nurse assess **first**?

- ☐ 1. a client with COPD with a PaO₂ of 56 mm Hg who is being discharged home on oxygen
- ☐ 2. a client with asthma with respirations of 36 breaths/min whose wheezing has diminished
- ☐ 3. a client with asthma who has a heart rate of 90 bpm and whose beta-blocker is scheduled to be administered now
- ☐ 4. a client who is scheduled for an angiogram now and is ready to be transported

146. The nurse is caring for a group of clients on a pulmonary unit. The nurse can delegate which task to unlicensed assistive personnel (UAP)?

- ☐ 1. Assisting a client with adjusting his or her nasal cannula
- ☐ 2. Making adjustments to flow rates based on client responses
- ☐ 3. Monitoring a client for adverse effects of oxygen therapy
- ☐ 4. Assessing a client for the best method of oxygen delivery

147. A confused client with carbon monoxide poisoning experiences dizziness when ambulating to the bathroom. The nurse should:

- ☐ 1. put all four side rails up on the bed.
- ☐ 2. ask the unlicensed assistive personnel (UAP) to place restraints on the client's upper extremities.
- ☐ 3. request that the client's roommate put the call light on when the client is attempting to get out of bed.
- ☐ 4. check on the client at regular intervals to ascertain the need to use the bathroom.

148. The nurse should use which type of precautions for a client being admitted to the hospital with suspected tuberculosis?

- ☐ 1. hand hygiene
- ☐ 2. contact precautions
- ☐ 3. droplet precautions
- ☐ 4. airborne precautions

149. A client has developed a hospital-acquired pneumonia. When preparing to administer cephalexin 500 mg, the nurse notices that the pharmacy sent cefazolin. What should the nurse do? Select all that apply.

- ☐ 1. Administer the cefazolin.
- ☐ 2. Verify the medication prescription as written by the healthcare provider (HCP).
- ☐ 3. Contact the pharmacy and speak to a pharmacist.
- ☐ 4. Request that cephalexin be sent promptly.
- ☐ 5. Return the cefazolin to the pharmacy.

150. A nurse receives the taped change-of-shift report for assigned clients and prioritizes client rounds. In what order from first to last should the nurse assess these clients? All options must be used.

1. a client who has an endotracheal tube and who will be transferred to a long-term respiratory care unit that day

2. a client with type 2 diabetes who had a cerebrovascular accident 4 days ago

3. a client with cellulitis of the left lower extremity with a fever of 100.8°F (38.2°C)

4. a client receiving D5W IV at 125 mL/h with 75 mL remaining

151. The nurse is a member of a team that is planning a client-centered,

community-based approach to care of clients with chronic obstructive pulmonary disease (COPD). In which areas should the team focus on improving quality of care and delivery? Select all that apply.

- ☐ 1. the community
- ☐ 2. clinical information systems
- ☐ 3. delivery system design
- ☐ 4. administrative leadership
- ☐ 5. acute care setting

152. The nurse is caring for a client admitted for pneumonia with a history of hypertension and heart failure. The client has reported at least one fall in the last 3 months. The client may ambulate with assistance, has a saline lock in place, and has demonstrated appropriate use of the call light to request assistance. Using the Morse Fall Scale (see chart), what is this client's total score and risk level?

Morse Fall Scale

Item	Scale	Scoring
1. History of falling; immediate or within 3 months	No 0 Yes 25	
2. Secondary diagnosis	No 0 Yes 15	
3. Ambulatory aid Bed rest/nurse assist Crutches/cane/walker Furniture	0 15 30	
4. IV/Heparin Lock	No 0 Yes 20	
5. Gait/Transferring Normal/bedrest/ immobileWeak Impaired	0 10 20	
6. Mental status Oriented to own ability Forgets limitations	0 15	

- ☐ 1. 20, low risk
- ☐ 2. 30, medium risk

- ☐ 3. 40, medium risk
- ☐ 4. 60, high risk

153. The nurse is caring for a client who has been placed on droplet precautions. Which protective gear is required to take care of this client? Select all that apply.

- ☐ 1. gloves
- ☐ 2. gown
- ☐ 3. surgical mask
- ☐ 4. glasses
- ☐ 5. respirator

154. While making rounds, the nurse finds a client with COPD sitting in a wheelchair, slumped over a lunch tray. After determining the client is unresponsive and calling for help, the nurse's **first** action should be to:

- ☐ 1. push the "code blue" (emergency response) button.
- ☐ 2. call the rapid response team.
- ☐ 3. open the client's airway.
- ☐ 4. call for a defibrillator.

155. The nurse is caring for a client with pneumonia who is confused about time and place and has intravenous fluids infusing. Despite the nurse's attempt to reorient the client and then provide distraction, the client has begun to pull at the IV tubing. After increasing the frequency of observation, in which order should the nurse implement interventions to ensure the client's safety? All options must be used.

1. Review the client's medications for interactions that may cause or increase confusion.

2. Assess the client's respiratory status including oxygen saturation.

3. Ensure the client does not need toileting or pain medications.

4. Contact the healthcare provider (HCP), and request a prescription for soft wrist restraints.

156. The nurse's assignment consists of four clients. After receiving shift report, in which order from first to last should the nurse assess these clients? All options must be used.

1. an 85-year-old client with bacterial pneumonia, temperature of 102.2°F (42°C), and shortness of breath

2. a 60-year-old client with chest tubes who is 2 days postoperative following a thoracotomy for lung cancer and is requesting something for pain

3. a 35-year-old client with suspected tuberculosis who has a cough

4. a 56-year-old client with emphysema who has a scheduled dose of a bronchodilator due to be administered, with no report of acute respiratory distress

157. The unlicensed assistive personnel (UAP) reports to the registered nurse (RN) that a client admitted with pneumonia is very diaphoretic. The nurse reviews the vital signs in the medical record obtained by the UAP. What should the nurse do? Select all that apply.

Vital Signs			
Time	0800	1000	1200
Temperature	38.3°C		38.8°C
Pulse	90	104	118
Respirations	16	18	24
Blood Pressure	112/74	110/68	116/78
Spo ₂	93%	92%	92%

- ☐ 1. Assure the client is maintaining complete bed rest.
- ☐ 2. Check the urine output.
- ☐ 3. Ask the client to drink more fluids.
- ☐ 4. Notify the healthcare provider (HCP).
- ☐ 5. Administer acetaminophen as prescribed.

Answers, Rationales, and Test-Taking Strategies

*The answers and rationales for each question follow below, along with keys () to the client need (CN) and cognitive level (CL) for each question. In addition, you will also see a glossary icon () highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out*

worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 12–23 and pages 35–36 in Part 1 of this book.

The Client with an Upper Respiratory Tract Infection

1. 1. At this time, there is no strong research evidence to warrant recommendations of herbal products for management of colds; further study is needed to show evidence of therapeutic effects and indications. Antibiotics are effective against bacteria; the head cold may have a viral cause. An uncomplicated upper respiratory tract infection subsides within 2 to 3 weeks. There may be a drug-drug interaction with herbal products and prescriptions.

CN: Basic care and comfort; CL: Synthesize

2. 1,4,5. Antihistamines have an anticholinergic action and a drying effect and reduce nasal, salivary, and lacrimal gland hypersecretion (runny nose, tearing, and itching eyes). An adverse effect is drowsiness, so operating machinery and driving are not recommended. There is also an additive depressant effect when alcohol is combined with antihistamines, so alcohol should be avoided during antihistamine use. The client should ensure adequate fluid intake of at least 2,000 mL (about eight glasses) per day due to the drying effect of the drug. Antihistamines have no antibacterial action, and are not used to treat nasal infections. The effect of antihistamines is prompt, not delayed.

CN: Pharmacological and parenteral therapies; CL: Create

3. 3. When using an intranasal inhaler, it is important to close off one nostril while inhaling the spray into the other nostril to ensure the best inhalation of the spray. Use of the inhaler is not limited to mornings and bedtime. The canister should be shaken immediately before use. The inhaler tip should be inserted into the nostril and pointed toward the outside nostril wall to maximize inhalation of the medication.

CN: Pharmacological and parenteral therapies; CL: Evaluate

4. 4. A client recovering from an upper respiratory tract infection should

report decreasing or no nasal discharge and obstruction. Daily fluid intake should be increased to more than 1 L every 24 hours to liquefy secretions. The temperature should be below 100°F (37.8°C) with no chills or diaphoresis. A productive cough with chest pain indicates a pulmonary infection, not an upper respiratory tract infection.

CN: Physiological adaptation; CL: Evaluate

5. 2. The client should blow the nose before instilling nose drops. Instilling nose drops is a clean technique. The dropper should be cleaned after each administration, but it does not need to be changed. The client should assume a position that will allow the medication to reach the desired area; this is usually a supine position.

CN: Pharmacological and parenteral therapies; CL: Evaluate

6. 3,4. The client with chronic sinusitis should be instructed to take hot showers in the morning and evening to promote drainage of secretions. There is no need to limit caffeine intake. Performing postural drainage will inhibit removal of secretions, not promote it. Clients should elevate the head of the bed to promote drainage. Clients should report all temperatures higher than 100.4°F (38°C) because a temperature that high can indicate infection. The client should increase, not limit, fluid intake; a 24-hour fluid intake of 2,000 to 3,000 mL would be appropriate.

CN: Reduction of risk potential; CL: Synthesize

7. 4. It is important for clients with allergic rhinitis to determine the precipitating factors so that they can be avoided. Keeping a diary can help identify these triggers. Nasal decongestant sprays should not be used regularly because they can cause a rebound effect. Antibiotics are not appropriate for allergic rhinitis because an infection is not present. Increasing activity will not control the client's symptoms; in fact, walking outdoors may increase them if the client is allergic to pollen.

CN: Health promotion and maintenance; CL: Synthesize

8. 7.5 mL

$$300 \text{ mg} / X = 200 \text{ mg} / 5 \text{ mL}$$

$$X = 7.5 \text{ mL}.$$

CN: Pharmacological and parenteral therapies; CL: Apply

9. 4. Adverse effects of pseudoephedrine are experienced primarily in the cardiovascular system and through sympathetic effects on the central nervous system (CNS). The most common CNS adverse effects include restlessness, dizziness, tension, anxiety, insomnia, and weakness. Common cardiovascular adverse effects include tachycardia, hypertension, palpitations, and arrhythmias. Constipation and diplopia are not adverse effects of pseudoephedrine. Tachycardia, not bradycardia, is an adverse effect of pseudoephedrine.

CN: Pharmacological and parenteral therapies; CL: Analyze

The Client Undergoing Nasal Surgery

10. 4. Epistaxis, or nosebleed, is a common, sudden emergency. Commonly, no apparent explanation for the bleeding is known. With significant blood loss, systemic symptoms, such as vertigo, increased pulse, shortness of breath, decreased blood pressure, and pallor, will occur. Because aerobic exercise may increase blood pressure and increased blood pressure can cause epistaxis, the client with hypertension should avoid it. Aspirin inhibits platelet aggregation, reducing the ability of the blood to clot. The client should continue to take his antihypertension medication, ramipril. Posterior nasal packing should be left in place for 1 to 3 days.

CN: Health promotion and maintenance; CL: Synthesize

11. 2. Because of the dense nasal packing, bleeding may not be apparent through the nasal drip pad. Instead, the blood may run down the throat, causing the client to swallow frequently. The back of the throat, where the blood will be apparent, can be assessed with a flashlight. An accumulation of blood in the stomach can cause nausea and vomiting, but nausea would not be the initial indicator of bleeding. An increased respiratory rate occurs in

shock but is not an early sign of bleeding in a client who has undergone nasal surgery. Increased pain warrants further assessment but is not an indicator of bleeding.

CN: Reduction of risk potential; CL: Analyze

12. 1. The client should be instructed to avoid any activities that cause Valsalva's maneuver (e.g., constipation, vigorous coughing, exercise) in order to reduce bleeding and stress on suture lines. The client should not take aspirin because of its antiplatelet properties, which may cause bleeding. Oral hygiene is important to rid the mouth of old dried blood and to enhance the client's appetite. Cool compresses, not heat, should be applied to decrease swelling and control discoloration of the area.

CN: Physiological adaptation; CL: Create

13. 2. Constipation can cause straining during defecation, which can induce bleeding. Showering is not contraindicated. The client should take measures to prevent coughing, which can cause bleeding. The client should avoid blowing the nose for 48 hours after the packing is removed. Thereafter, the client should blow the nose gently, using the open-mouth technique to minimize bleeding in the surgical area.

CN: Physiological adaptation; CL: Evaluate

14. 4. Aspirin-containing medications should be discontinued for 2 weeks before surgery to decrease the risk of bleeding. Nasal packing is usually removed the day after surgery. Normal saline nose drops are not routinely administered preoperatively. The results of the surgery will not be obvious immediately after surgery because of edema and ecchymosis.

CN: Reduction of risk potential; CL: Create

15. 3. Immediately after nasal surgery, ineffective breathing patterns may develop as a result of the nasal packing and nasal edema. Nasal packing may dislodge, leading to obstruction. Assessing for airway obstruction is a priority. Assessing for pain is important, but it is not as high a priority as assessment of the airways. It is too early to detect ecchymosis. Measuring intake and output is not typically a **priority** nursing assessment after nasal surgery.

 CN: Physiological adaptation; CL: Analyze

16. 4. Applying cold compresses helps to decrease facial swelling and pain from edema. Analgesics may decrease pain, but they do not decrease edema. A corticosteroid nasal spray would not be administered postoperatively because it can impair healing. Use of a bedside humidifier promotes comfort by providing moisture for nasal mucosa, but it does not decrease edema.

 CN: Basic care and comfort; CL: Synthesize

17. 1. Frequent mouth care is important to provide comfort and encourage eating. Mouth care promotes moist mucous membranes. Nose drops cannot be used with nasal packing in place. When sneezing and coughing, the client should do so with the mouth open to decrease the chance of dislodging the packing. Gargling should not be attempted with packing in place.

 CN: Basic care and comfort; CL: Create

18. 4. The client should assume a sitting position and lean forward. Firm pressure should be applied to the soft portion of the nose for approximately 10 minutes. Tilting the head backward can cause the client to swallow blood, which can obscure the amount of bleeding and also can lead to nausea. Ice compresses may be applied, but the client should not lie flat. Blowing the nose is to be avoided because it can increase bleeding.

 CN: Reduction of risk potential; CL: Synthesize

19. 3. Posterior packing may alter the respiratory status of the client, especially in elderly clients, causing hypoventilation. Clients should be observed carefully for changes in level of consciousness, respiratory rate, and heart rate and rhythm after the insertion of the packing. Vertigo does not occur as a result of the insertion of posterior packing. Bell's palsy, a disorder of the seventh cranial nerve, is not associated with epistaxis or nasal packing. Loss of gag reflex does not occur as a result of the insertion of posterior packing.

 CN: Reduction of risk potential; CL: Analyze

The Client with Cancer of the Larynx

20. 4. The nurse must maintain patency of the airway with frequent suctioning of the laryngectomy tube that can become occluded from secretions, blood, and mucus plugs. Once the client is hemodynamically stable, getting out of bed should be encouraged to prevent postoperative complications. Vital signs should be monitored more frequently in a postoperative client. A swallow study is done at approximately 5 to 7 days after surgery, prior to starting oral intake.

CN: Physiological adaptation; CL: Synthesize

21. 4. The client has undergone body changes and permanent loss of verbal communication. He may feel isolated and insecure. The nurse can encourage him to express his feelings and use this information to develop an appropriate plan of care. Discussing the client's behavior with his wife may not reveal his feelings. Exploring future plans is not appropriate at this time because more information about the client's behavior is needed before proceeding to this level. The nurse can respect the client's need for privacy while also encouraging him to express his feelings.

CN: Psychosocial adaptation; CL: Synthesize

22. 1. A client should be suctioned for no longer than 10 seconds at a time. Suctioning for longer than 10 seconds may reduce the client's oxygen level so much that the client becomes hypoxic.

CN: Reduction of risk potential; CL: Apply

23. 1. The recommended technique is to use a sterile catheter each time the client is suctioned. There is a danger of introducing organisms into the respiratory tract when strict aseptic technique is not used. Reusing a suction catheter is not consistent with aseptic technique. The nurse does not use a clean catheter when suctioning a tracheostomy or a laryngectomy; it is a sterile procedure.

CN: Reduction of risk potential; CL: Apply

24. 4. Changes in body image are expected after a laryngectomy, and the nurse should first explore what is upsetting the client the most at this time. Many clients are concerned about how their family members will respond to the physical changes that have occurred as a result of a laryngectomy, but

discussing the importance of family support is not helpful; instead, the nurse should allow the client to communicate any negative feelings or concerns that exist because of the surgery. The client's feelings are not related to a knowledge deficit, and therefore, it is too early to begin teaching about stoma care. It is also not helpful to offer reassurances about the change in appearance; the client will require time to adjust to the changed body image.

CN: Psychosocial adaptation; CL: Synthesize

25. 1. The tracheostomy tube, ties, and gauze pad are positioned correctly; the nurse team leader should be sure the client is comfortable. The tracheostomy tube ties should be tied in a square knot on the side of the neck and alternate sides of the neck when the ties are changed. The full part of the gauze square should be placed under the tracheostomy tube to absorb drainage. There is no indication the ties need to be changed; an additional gauze pad is not necessary; if necessary, the current gauze square should be changed rather than adding an additional pad.

CN: Basic care and comfort; CL: Evaluate

26. 1,3. The primary risk factors for laryngeal cancer are smoking and alcohol abuse. Smoking cessation is most successful with a support group or counseling. Heavy drinking should be avoided since the risk increases with amount of alcohol consumption. HEPA filters help trap small particles and allergens to reduce allergy symptoms and asthma. Poor oral hygiene is not a risk factor, nor is overusing the voice.

CN: Health promotion and maintenance; CL: Create

27. 3. Hoarseness occurring longer than 2 weeks is a warning sign of laryngeal cancer. The nurse should first assess other signs, such as a lump in the neck or throat, persistent sore throat or cough, earache, pain, and difficulty swallowing (dysphagia). Gargling with salt water may lead to increased irritation. There is no indication of infection warranting an antibiotic. An oral analgesic would provide only temporary relief of discomfort if hoarseness is accompanied by a sore throat.

CN: Physiological adaptation; CL: Synthesize

28. 1. Immediately after surgery, the client should be maintained in a

position with the head of the bed elevated 30 to 40 degrees (semi-Fowler's position) to decrease tissue edema, facilitate breathing, and decrease pain related to edema formation. Immediately postoperatively, the client should be provided alternative means of communicating, such as a communication board. As healing progresses and edema subsides, a speech therapist should work with the client to explore various voice restoration options, such as the use of a voice prosthesis, electrolarynx, artificial larynx, or esophageal speech. Food is not initiated in the immediate postoperative phase; enteral feedings are usually used to meet nutritional needs until edema subsides. Irrigation of the drainage tubes is an inappropriate action.

CN: Basic care and comfort; CL: Synthesize

29. 3. It is important that the client be able to communicate his or her feelings about the body image changes that have occurred as a result of surgery. Open communication helps promote adjustment. The client may not regain the ability to taste and smell food because of no longer breathing through the nose or because of radiation therapy treatments, or both. A gastrostomy tube would not typically be placed after a total laryngectomy, nor would it be necessary for the client to demonstrate sterile suctioning technique for stoma care. The client would use clean technique.

CN: Physiological adaptation; CL: Evaluate

30. 2. Adequate humidity should be provided in the home to help keep secretions moist. A bedside humidifier is recommended. A high fluid intake is also important to liquefy secretions. Mouth care is important to prevent drying of mucous membranes and should be performed frequently throughout the day, especially before and after meals, to help stimulate appetite. The client may eat any food that can be chewed and swallowed comfortably. The client may resume physical activity as tolerated.

CN: Reduction of risk potential; CL: Synthesize

The Client with Pneumonia

31. 3. The client's ABG levels are the most sensitive indicator of the effectiveness of the client's oxygen therapy. Cyanosis is a late sign of decreased oxygenation and is not a reliable indicator. The client's respiratory

rate and level of consciousness may be altered because of other problems not related to the client's oxygenation.

 CN: Physiological adaptation; CL: Evaluate

32. 2. Restraints should be secured to the bed frame, not the side rails, to ensure that the side rails can be raised and lowered safely. Circulation checks, reevaluating need for restraints, and documentation should be done every 1 to 2 hours. Medical restraint prescriptions must be renewed and signed by an **HCP**  every 24 hours.

 CN: Safety and infection control; CL: Synthesize

33. 1. The client's age is a predisposing factor for pneumonia; pneumonia is more common in elderly or debilitated clients. Other predisposing factors include smoking, upper respiratory tract infections, malnutrition, immunosuppression, and the presence of a chronic illness. Osteoarthritis, a nutritionally sound vegetarian diet, and frequent bathing are not predisposing factors for pneumonia.

 CN: Reduction of risk potential; CL: Analyze

34. 1,3,5. A respiratory assessment, which includes auscultating breath sounds and assessing the color of the nail beds, is a priority for clients with pneumonia. Assessing for the presence of chest pain is also an important respiratory assessment as chest pain can interfere with the client's ability to breathe deeply. Auscultating bowel sounds and assessing for peripheral edema may be appropriate assessments, but these are not priority assessments for the client with pneumonia.

 CN: Physiological adaptation; CL: Analyze

35. 2. A sputum specimen is obtained for culture to determine the causative organism. After the organism is identified, an appropriate antibiotic can be prescribed. Beginning antibiotic therapy before obtaining the sputum specimen may alter the results of the test. Urinalysis, a chest radiograph, and a red blood cell count do not need to be obtained before initiation of antibiotic therapy for pneumonia.

 CN: Reduction of risk potential; CL: Apply

36. 3. It is essential to monitor serum creatinine in the client receiving an aminoglycoside antibiotic because of the potential of this type of drug to cause acute tubular necrosis. Aminoglycoside antibiotics do not affect serum sodium, potassium, or calcium levels.

CN: Pharmacological and parenteral therapies; CL: Analyze

37. 4. The nurse should determine if the client is allergic to penicillin prior to administering the drug. History of seizures, recent infections, and a cardiac history are not contraindications for this client to receive penicillin. While important to know, recent infections will not preclude this client receiving penicillin at this time.

CN: Pharmacological and parenteral therapies; CL: Apply

38. 3. Frequent changes of the bedsheets are appropriate for this client because of the diaphoresis. Diaphoresis produces general discomfort, and the client should be kept dry to promote comfort and prevent skin irritation. The client should change position every 2 hours. Nasotracheal suctioning is not indicated with the client's productive cough. The client can ambulate to the bathroom, but the nurse should offer assistance as needed.

CN: Basic care and comfort; CL: Synthesize

39. 1. Exudate in the alveoli interferes with ventilation and the diffusion of gases in clients with pneumonia. During the acute phase of the illness, it is essential to reduce the body's need for oxygen at the cellular level; bed rest is the most effective method for doing so. Bed rest does not decrease coughing or promote clearance of secretions, and it does not reduce pain when taking deep breaths.

CN: Physiological adaptation; CL: Evaluate

40. 3. Chest pain in pneumonia is generally caused by friction between the pleural layers. It is more severe on inspiration than on expiration, secondary to chest wall movement. Pleuritic chest pain is usually described as sharp, not mild or aching. Pleuritic chest pain is not localized to the sternum, and it is not the result of a muscle spasm.

CN: Physiological adaptation; CL: Analyze

41. 4. The pleuritic pain is triggered by chest movement and is particularly severe during coughing. Splinting the chest wall will help reduce the discomfort of coughing. Deep breathing is essential to prevent further atelectasis. Abdominal breathing is not as effective in decreasing pleuritic chest pain as is splinting of the rib cage. Incentive spirometry facilitates effective deep breathing but does not decrease pleuritic chest pain.

CN: Physiological adaptation; CL: Synthesize

42. 1,3. Aspirin is administered to clients with pneumonia because it is an analgesic that helps control chest discomfort and an antipyretic that helps reduce fever. Aspirin has an anticoagulant effect, but that is not the reason for prescribing it for a client with pneumonia, and the use of the drug will be short term. Aspirin does not affect the respiratory rate and does not facilitate expectoration of secretions.

CN: Pharmacological and parenteral therapies; CL: Evaluate

43. 3. Clients who are experiencing hypoxia characteristically exhibit irritability, restlessness, or anxiety as initial mental status changes. As the hypoxia becomes more pronounced, the client may become confused and combative. Coma is a late clinical manifestation of hypoxia. Apathy and depression are not symptoms of hypoxia.

CN: Physiological adaptation; CL: Analyze

44. 1. Docusate sodium is a stool softener that allows fluid and fatty substances to enter the stool and soften it. Docusate sodium does not lubricate the stool, increase stool bulk, or stimulate peristalsis.

CN: Pharmacological and parenteral therapies; CL: Apply

45. 2. An expected outcome for a client recovering from pneumonia would be the ability to perform activities of daily living without experiencing dyspnea. A respiratory rate of 25 to 30 breaths/min indicates the client is experiencing tachypnea, which would not be expected on recovery. A weight loss of 5 to 10 lb (2.27 to 4.53 kg) is undesirable; the expected outcome would be to maintain normal weight. A client who is recovering from pneumonia should experience decreased or no chest pain.

CN: Management of care; CL: Evaluate

The Client with Tuberculosis

46. 1. Implementing airborne precautions for possible TB requires a private room assignment. In addition to isolating the client by using a private room, engineering controls can help prevent the spread of TB; a room at the end of the hall will aid in controlling airflow direction and can prevent contamination of air in adjacent areas. Confidentiality is provided for every client, regardless of the client's room location. Sunlight is not a component of isolation precautions.

 CN: Physiological adaptation; CL: Apply

47. 1. There is a high risk and potential for tuberculosis, and airborne precautions should be implemented immediately to prevent the spread of infection. After initiating precautions, the nurse can start the oxygen, check the vital signs, and collect the sputum specimen.

 CN: Safety and infection control; CL: Synthesize

48. 3. Streptomycin can cause toxicity to the eighth cranial nerve, which is responsible for hearing, balance, and body position sense. Nephrotoxicity is a side effect that would be indicated with an increase in creatinine. Streptomycin does not cause difficulty in swallowing. Streptomycin is given via intramuscular injection.

 CN: Pharmacological and parenteral therapies; CL: Analyze

49. 4. The nurse should tell the client that it is necessary to take all of these medications because combination drug therapy prevents bacterial resistance; they will be administered throughout the hospitalization to maintain blood levels. The **HCP**  will review the prescriptions per hospital policy because the client is being admitted to the hospital; there is no duplication between any of the drugs being prescribed for this client. It is not necessary to ask the pharmacist to check for drug interactions as these drugs are commonly used together.

 CN: Pharmacologic and parenteral therapy; CL: Synthesize

50. 2. Ensuring that the client is well educated about tuberculosis is the highest **priority**. Education of the client and family is essential to help the

client understand the need for completing the prescribed drug therapy to cure the disease. Offering the client emotional support, coordinating various agency services, and assessing the environment may be part of the care for the client with tuberculosis; however, these interventions are of less importance than education about the disease process and its treatment.

CN: Basic care and comfort; CL: Synthesize

51. 3. The tuberculin test is positive. The test should be interpreted 2 to 3 days after administering the purified protein derivative (PPD) by measuring the size of the firm, raised area (induration). Positive responses indicate that the client may have been exposed to the tuberculosis bacteria. A negative response is indicated by the absence of a firm, raised area, or an area that is <5 mm in diameter. Since the test is positive, it is not necessary to redo the test. The test is positive, not false.

CN: Physiological adaptation; CL: Analyze

52. 1. The Mantoux test is administered via intradermal injection. The appropriate technique for an intradermal injection includes holding the needle and syringe almost parallel to the client's skin, keeping the skin slightly taut when the needle is inserted, and inserting the needle with the bevel side up. There is no need to aspirate, a technique that assesses for incorrect placement in a blood vessel, when giving an intradermal injection. The injection site is not massaged.

CN: Pharmacological and parenteral therapies; CL: Apply

53. 3. An induration (palpable raised hardened area of skin) of more than 5 to 15 mm (depending upon the person's risk factors) to 10 Mantoux units is considered a positive result, indicating TB infection. An induration of >5 mm is found in HIV-positive individuals, those with recent contacts with persons with TB, persons with nodular or fibrotic changes on chest x-ray consistent with old healed TB, or clients with organ transplants or immunosuppressed. An induration of >10 mm is positive, and the client may be a recent arrival (<5 years) from high-prevalent countries, injection drug user, resident or an employee of high-risk congregate settings (e.g., prisons, long-term care facilities, hospitals, homeless shelters), or mycobacteriology lab personnel. An induration of >10 mm is also considered positive in persons with clinical

conditions that place them at high risk (e.g., diabetes, prolonged corticosteroid therapy, leukemia, end-stage renal disease, chronic malabsorption syndromes, low body weight), a child <4 years of age, or a child or adolescents exposed to adults in high-risk categories.

CN: Physiological adaptation; CL: Analyze

54. 4. Elderly persons are believed to be at higher risk for contracting tuberculosis because of decreased immunocompetence. Other high-risk populations in the United States and Canada include the urban poor, clients with acquired immunodeficiency syndrome, and minority groups.

CN: Safety and infection control; CL: Analyze

55. 2,4. When teaching the client how to avoid the transmission of tubercle bacilli, it is important for the client to understand that the organism is transmitted by droplet infection. Therefore, covering the mouth and nose when sneezing, using paper tissues to cough in with prompt disposal, indicates that the client has understood the nurse's instructions about preventing the spread of airborne droplets. It is not essential to discard clothing, nor does the client need to be isolated from family members. The client does not need to avoid crowds.

CN: Health promotion and maintenance; CL: Evaluate

56. 2. A positive Mantoux skin test indicates that the client has been exposed to tubercle bacilli. Exposure does not necessarily mean that active disease exists. A positive Mantoux test does not mean that the client has developed resistance. Unless involved in treatment, the client may still develop active disease at any time. Immunity to tuberculosis is not possible.

CN: Reduction of risk potential; CL: Analyze

57. 2. INH competes for the available vitamin B₆ in the body and leaves the client at risk for development of neuropathies related to vitamin deficiency. Supplemental vitamin B₆ is routinely prescribed. Following a low-cholesterol diet, getting extra rest, and avoiding excessive sun exposure will not prevent the development of peripheral neuropathies.

CN: Pharmacological and parenteral therapies; CL: Synthesize

58. 3. INH interferes with the effectiveness of hormonal contraceptives, and female clients of childbearing age should be counseled to use an alternative form of birth control while taking the drug. INH does not increase the risk of vaginal infection, nor does it affect the ova or ovulation.

CN: Pharmacological and parenteral therapies; CL: Apply

59. 3. Tuberculosis can be controlled but never completely eradicated from the body. Periods of intense physical or emotional stress increase the likelihood of recurrence. Clients should be taught to recognize the signs and symptoms of a potential recurrence. Weather and activity levels are not related to recurrences of tuberculosis.

CN: Physiological adaptation; CL: Analyze

60. 2. Statistics show that of the four geographic areas described, most cases of tuberculosis are found in inner-core residential areas of large cities, where health and sanitation standards tend to be low. Substandard housing, poverty, and crowded living conditions also generally characterize these city areas and contribute to the spread of the disease. Farming areas have a low incidence of tuberculosis. Variations in water standards and industrial pollution are not correlated to tuberculosis incidence.

CN: Safety and infection control; CL: Analyze

61. 4. Isoniazid and rifampin are hepatotoxic. The client should be warned to limit intake of alcohol during drug therapy. The drug should be taken on an empty stomach. If antacids are needed for gastrointestinal distress, they should be taken 1 hour before or 2 hours after the drug is administered. The client should not double the dose of the drug because of potential toxicity. The client taking the drug should avoid foods that are rich in tyramine, such as cheese and dairy products, or the client may develop hypertension.

CN: Pharmacological and parenteral therapies; CL: Create

62. 2,4,5. A potential adverse effect of rifampin is hepatotoxicity. Clients should be instructed to avoid alcohol intake while taking rifampin and keep follow-up appointments for periodic monitoring of liver enzyme levels to detect liver toxicity. Rifampin causes the urine to turn an orange color, and the client should understand that this is normal. It is not necessary to restrict

protein intake in the diet or have the eyes examined due to rifampin therapy.

CN: Pharmacological and parenteral therapies; CL: Create

63. 1. Directly observed therapy (DOT) can be implemented with clients who are not compliant with drug therapy. In DOT, a responsible person, who may be a family member or an **HCP** , observes the client taking the medication. Visiting the client, changing the prescription, or threatening the client will not ensure compliance if the client will not or cannot follow the prescribed treatment.

CN: Safety and infection control; CL: Synthesize

The Client with Chronic Obstructive Pulmonary Disease

64. 2,4. Close proximity to smoking, fire, and small electrical appliances can be a fire hazard and should be avoided. The use of gauze is helpful in preventing skin irritation from the constant pressure and friction of the oxygen tubing. Typically, oxygen needs are lower at rest and during sleep. Increasing oxygen flow should be done at the discretion of the prescribing healthcare provider and not the client. Water-soluble lubricants are considered safer than petroleum-based lubricants. Small liquid oxygen tanks are easier to transport during travel than pressurized tanks. Use of microwave ovens for cooking is considered safe for those using supplemental oxygen.

CN: Reduction of risk potential CL: Create

65. 2,3. The cough reflex for these clients promotes airway clearance. While the guaifenesin may thin secretions and facilitate expectoration, dextromethorphan suppresses the cough and should not be used with chronic bronchitis. Pseudoephedrine can increase blood pressure and increase urinary retention with an enlarged prostate and should be avoided. The albuterol and ipratropium is expected, since it promotes bronchial dilation. Lisinopril is an ACE inhibitor and useful in reducing blood pressure. The tamsulosin is commonly prescribed to treat benign prostate hypertrophy.

CN: Reduction of risk potential; CL: Synthesize

66. 3,4,5. High humidity has been shown to increase the work of breathing. Carrying a metered-dose inhaler can facilitate early intervention if

bronchospasm and shortness of breath should occur. Smoking cessation is difficult to achieve but very important in preventing COPD progression. Pulmonary rehabilitation programs are a great source of support for health promotion and maintenance for clients with COPD. Both the pneumococcal and influenza vaccines can help protect against respiratory infections.

CN: Reduction of risk potential; CL: Create

67. 3. Crackles auscultated in the lung field indicate excessive fluid, a problem that requires immediate intervention. Pursed-lip breathing and a prolonged expiratory phase, circumoral cyanosis, and increased anterior-posterior diameter of the chest (resulting in “barrel chest”) are not unusual findings for clients with emphysema.

CN: Physiological adaptation; CL: Analyze

68. 4. Inability to speak could indicate respiratory distress. Pursed-lip breathing, while it is an abnormal finding, is not indicative of respiratory distress. Distant heart sounds could indicate heart failure but are not indicative of any distress. Diminished lung sounds may be normal for this client, and do not require immediate intervention.

CN: Physiological adaptation; CL: Analyze

69. 2,1,3,4. The nurse should first instruct the client to relax the neck and the shoulders and then take several normal breaths. After taking a breath in, the client should pucker the lips and finally breathe out through pursed lips.

CN: Health promotion and maintenance; CL: Apply

70. 2. Clients with chronic COPD have CO₂ retention, and the respiratory drive is stimulated when the Po₂ decreases. The heart rate, respiratory rate, and blood pressure should be evaluated to determine if the client is hemodynamically stable. Symptoms, such as dyspnea, should also be assessed. After assessing the vital signs, the nurse should assist the client as needed to assume the most comfortable position for breathing. Oxygen supplementation, if indicated, should be titrated upward in small increments. There is no indication that the client is experiencing respiratory distress requiring intubation.

 CN: Physiological adaptation; CL: Synthesize

71. 1. A client with COPD is at high risk for development of respiratory infections. COPD is slowly progressive; therefore, maintaining current status and establishing a goal that the client will require less supplemental oxygen are unrealistic expectations. Treatment may slow progression of the disease, but permanent improvement is highly unlikely.

 CN: Management of care; CL: Synthesize

72. 1,2,3,4. The therapeutic range for serum theophylline is 10 to 20 mcg/mL (55.5 to 111 $\mu\text{mol/L}$). At higher levels, the client will experience signs of toxicity such as nausea, vomiting, seizures, and insomnia. The nurse should instruct the client to report these signs and to keep appointments to have theophylline blood levels monitored. If the theophylline level is below the therapeutic range, the client may be at risk for more frequent exacerbations of the disease.

 CN: Physiological Integrity; CL: Apply

73. 4. Increasing dyspnea on exertion indicates that the client may be experiencing complications of COPD. Therefore, the client should notify the **HCP** . It is not necessary to avoid being around others. Pain is not a common symptom of COPD. Clients with COPD use low-flow oxygen supplementation (1 to 2 L/min) to avoid suppressing the respiratory drive, which, for these clients, is stimulated by hypoxia.

 CN: Basic care and comfort; CL: Evaluate

74. 4. Cigarette smoking is the primary cause of COPD. Other risk factors include exposure to environmental pollutants and chronic asthma. Participating in an aerobic exercise program, although beneficial, will not decrease the risk of COPD. Insufficient protein intake and exposure to people with respiratory infections do not increase the risk of COPD.

 CN: Health promotion and maintenance; CL: Synthesize

75. 4. Pursed-lip breathing prolongs exhalation and prevents air trapping in the alveoli, thereby promoting carbon dioxide elimination. By prolonging exhalation and helping the client relax, pursed-lip breathing helps the client

learn to control the rate and depth of respiration. Pursed-lip breathing does not promote the intake of oxygen, strengthen the diaphragm, or strengthen intercostal muscles.

CN: Physiological adaptation; CL: Evaluate

76. 1. A priority goal for the client with COPD is to manage the signs and symptoms of the disease process so as to maintain the client's functional ability. Chest pain is not a typical symptom of COPD. The carbon dioxide concentration in the blood is increased to an abnormal level in clients with COPD; it would not be a goal to increase the level further. Preventing infection would be a goal of care for the client with COPD.

CN: Basic care and comfort; CL: Synthesize

77. 2. Exhaling requires less energy than does inhaling. Therefore, lifting while exhaling saves energy and reduces perceived dyspnea. Pursing the lips prolongs exhalation and provides the client with more control over breathing. Lifting after exhaling but before inhaling is similar to lifting with the breath held. This should not be recommended because it is similar to Valsalva's maneuver, which can stimulate cardiac arrhythmias.

CN: Basic care and comfort; CL: Synthesize

78. 3. Right-sided heart failure is a complication of COPD that occurs because of pulmonary hypertension. Signs and symptoms of right-sided heart failure include peripheral edema, jugular venous distention, hepatomegaly, and weight gain due to increased fluid volume. Clubbing of nail beds is associated with conditions of chronic hypoxemia. Hypertension is associated with left-sided heart failure. Clients with heart failure have decreased appetites.

CN: Physiological adaptation; CL: Synthesize

79. 4. Exacerbations of COPD are commonly caused by respiratory infections. Coarse crackles and rhonchi would be auscultated as air moves through airways obstructed with secretions. In COPD, breath sounds are diminished because of an enlarged anteroposterior diameter of the chest. Expiration, not inspiration, becomes prolonged. Chest movement is decreased as lungs become overdistended.

CN: Physiological adaptation; CL: Analyze

80. 2. Clients who have a long history of COPD may retain carbon dioxide (CO_2). Gradually, the body adjusts to the higher CO_2 concentration, and the high levels of CO_2 no longer stimulate the respiratory center. The major respiratory stimulant then becomes hypoxemia. Administration of high concentrations of oxygen eliminates this respiratory stimulus and leads to hypoventilation. Oxygen can be drying if it is not humidified, but it does not cause coughing and dyspnea. Increased oxygen use will not create an oxygen dependency; clients should receive oxygen as needed. Oxygen is not contraindicated with the use of bronchodilators.

CN: Physiological adaptation; CL: Apply

81. 4. The client should eat high-calorie, high-protein meals to maintain nutritional status and prevent weight loss that results from the increased work of breathing. The client should be encouraged to eat small, frequent meals. A low-fat, low-cholesterol diet is indicated for clients with coronary artery disease. The client with COPD does not necessarily need to follow a sodium-restricted diet, unless otherwise medically indicated. There is no need for the client to eat bland, soft foods.

CN: Basic care and comfort; CL: Synthesize

82. 3. Theophylline is a bronchodilator that is administered to relax airways and decrease dyspnea. Theophylline is not used to treat infections and does not decrease or thin secretions.

CN: Pharmacological and parenteral therapies; CL: Evaluate

83. 1. The goal of effective coughing is to conserve energy, facilitate removal of secretions, and minimize airway collapse. The client should assume a sitting position with feet on the floor if possible. The client should bend forward slightly and, using pursed-lip breathing, exhale. After resuming an upright position, the client should use abdominal breathing to slowly and deeply inhale. After repeating this process three or four times, the client should take a deep abdominal breath, bend forward, and cough three or four times upon exhalation (“huff” cough). Lying flat does not enhance lung expansion; sitting upright promotes full expansion of the thorax. Shallow

breathing does not facilitate removal of secretions, and forceful coughing promotes collapse of airways. A side-lying position does not allow for adequate chest expansion to promote deep breathing.

CN: Basic care and comfort; CL: Create

The Client with Asthma

84. 3,4,5. Utilization of an MDI requires the following actions: shaking the MDI before use; exhaling prior to dispensing the medication; taking a deep breath to ensure the medication is distributed in the lungs and holding it for 10 seconds or as long as possible to disperse the medication into the lungs; and allowing 30 seconds between puffs to provide an adequate amount of inhalation medication. The client should rinse the plastic parts of the MDI and wipe them dry; the canister should not become wet.

CN: Pharmacological and parenteral therapies; CL: Evaluate

85. 4. In an acute asthma attack, diminished or absent breath sounds can be an ominous sign indicating lack of air movement in the lungs and impending respiratory failure. The client requires immediate intervention with inhaled bronchodilators, IV corticosteroids, and, possibly, IV theophylline. Administering oxygen and reassessing the client 10 minutes later would delay needed medical intervention, as would drawing blood for an arterial blood gas analysis. It would be futile to encourage the client to relax and breathe slowly without providing the necessary pharmacologic intervention.

CN: Management of care; CL: Synthesize

86. 3. Quick-acting bronchodilators are used in acute asthma to improve airflow and relieve symptoms; following treatment, tachycardia resolves as gas exchange and work of breathing are improved. SpO₂ and PEF rates improve, and wheezing from a constricted airway resolves. The normal inspiratory to expiratory ratio is 1:2.

CN: Physiological adaptation; CL: Evaluate

87. 2. The nurse instructs the client to administer the bronchodilator first (the beta-2 agonist always leads) in order to open the airway and allow for

improved delivery of the corticosteroid to the lung tissue, which follows after 1 minute between puffs. Using a spacer device with an MDI provides the best delivery of medication to the lungs.

CN: Pharmacological and parenteral therapies; CL: Synthesize

88. 1. The arterial blood gas reveals a respiratory acidosis with hypoxia. A quick-acting bronchodilator, albuterol, should be administered via nebulizer to improve gas exchange. Ipratropium is a maintenance treatment for bronchospasm that can be used with albuterol. A chest x-ray and sputum sample can be obtained once the client is stable.

CN: Physiological adaptation; CL: Synthesize

89. 3. Corticosteroids have an anti-inflammatory effect and act to decrease edema in the bronchial airways and decrease mucus secretion. Corticosteroids do not have a bronchodilator effect, act as expectorants, or prevent respiratory infections.

CN: Pharmacological and parenteral therapies; CL: Evaluate

90. 1,4. The client should shake the inhaler and hold it upright when administering the drug. The head should be tilted back slightly. The client should wait about 30 seconds between puffs. The mouth should be rinsed following the use of a corticosteroid MDI to decrease the likelihood of developing an oral infection. The client does not need to lie supine; instead, the client will likely to be able to breathe more freely if sitting upright.

CN: Pharmacological and parenteral therapies; CL: Evaluate

91. 1. Irregular heartbeats should be reported promptly to the care provider. Metaproterenol may cause irregular heartbeat, tachycardia, or anginal pain because of its adrenergic effect on beta-adrenergic receptors in the heart. It is not recommended for use in clients with known cardiac disorders. Metaproterenol does not cause constipation, pedal edema, or bradycardia.

CN: Pharmacological and parenteral therapies; CL: Analyze

92. 3. Use of oral inhalant corticosteroids such as flunisolide can lead to the development of oral thrush, a fungal infection. Once developed, thrush

must be treated by antifungal therapy; it will not resolve on its own. Fungal infections can develop even without overuse of the corticosteroid inhaler. Although good oral hygiene can help prevent development of a fungal infection, it cannot be used alone to treat the problem.

CN: Pharmacological and parenteral therapies; CL: Synthesize

93. 1,4,3,2. When using inhalers, clients should first shake the inhaler to activate the MDI and then breathe out through the mouth. Next, the client should activate the MDI while inhaling, hold the breath for 5 to 10 seconds, and then exhale normally.

CN: Pharmacological and parenteral therapies; CL: Apply

94. 4. Between attacks, breath sounds should be clear on auscultation with good airflow present throughout lung fields. Chest x-rays should be normal. The client should remain afebrile. Arterial blood gases should be normal.

CN: Physiological adaptation; CL: Evaluate

95. 1. Physical exercise is beneficial and should be incorporated as tolerated into the client's schedule. Peak flow numbers should be monitored daily, usually in the morning (before taking medication). Peak flow does not need to be monitored after each meal. Stressors in the client's life should be modified but cannot be totally eliminated. Although adequate sleep is important, it is not recommended that sedatives be routinely taken to induce sleep.

CN: Reduction of risk potential; CL: Create

96. 3. A common precipitator of asthma attacks is exposure to cigarette and cigar smoke. The client should avoid being in environments where there is exposure to smoke. Environmental exposure to toxins or heavy particulate matter can trigger asthma attacks; however, far fewer asthmatics are exposed to such toxins than are exposed to smoke. Valsalva's maneuver (holding the breath while defecating or bearing down) is associated with causing cardiac arrhythmias. Rarely, asthmatic attacks are triggered by exercising in cold weather.

CN: Reduction of risk potential; CL: Synthesize

97. 1. A cough productive of yellow sputum is the most likely indicator of a respiratory infection. The other signs and symptoms—wheezing, chest tightness, and increased respiratory rate—are all findings associated with an asthma attack and do not necessarily mean an infection is present.

CN: Physiological adaptation; CL: Analyze

98. 3. The hallmark signs of asthma are chest tightness, audible wheezing, and coughing. Inspiratory and expiratory wheezing is the result of bronchoconstriction. Even between exacerbations there may be some soft wheezing, so a finding of normal breath sounds would be expected in the absence of asthma. The expected finding is decreased forced expiratory volume (forced expiratory flow [FEF] is the flow [or speed] of air coming out of the lung during the middle portion of a forced expiration) due to bronchial constriction. Morning headaches are found in more advanced cases of COPD and signal nocturnal hypercapnia or hypoxemia.

CN: Physiological adaptation; CL: Analyze

The Client with Lung Cancer

99. 1. The nurse should first assess for bilateral breath sounds since a complication of central line insertion is a pneumothorax, which would cause an increase in respiratory rate and drop in oxygen, causing irritability. The nurse should also assess blood pressure and heart rate for the complication of bleeding. A chest x-ray will be performed to determine correct placement and complications. A central line was most likely placed because peripheral IV access was not available or adequate for the client. Repositioning may be considered after assessments are done.

CN: Physiological adaptation; CL: Synthesize

100. 2. The nurse should review the CBC with differential to evaluate the client's hemoglobin and hematocrit, which are abnormal and should be reported to the **HCP** . Anemia leads to decreased oxygen-carrying capacity of the blood. A client unable to compensate for the anemia may experience a profound sense of dyspnea. There has been a significant drop in the hemoglobin and hematocrit since the previous report, and these should be

reported to the HCP. The monocytes are within normal range. A₁C is a laboratory test evaluating glycosylated hemoglobin and is in the normal range. This test is used to diagnose diabetes and/or monitor diabetic glucose control over time. PT is a coagulation study reflecting liver function and clotting time and is in the normal range.

CN: Physiological adaptation; CL: Synthesize

101. 1. Risk factors for postoperative pulmonary complications include malnourishment, which is indicated by this client's height and weight. It is thought that emotional responses can affect overall health; however, not verbalizing one's feelings is not a contributing factor in postoperative pulmonary complications. The client's current activity level and age do not place her at increased risk for complications.

CN: Physiological adaptation; CL: Analyze

102. 1. Acknowledging the basic feeling the client expresses—fear—and asking an open-ended question allow the client to explain any fears. The other options dismiss the client's feelings and may give false reassurance or label the client's feelings. The client should be encouraged to explore feelings about a cancer diagnosis.

CN: Psychosocial adaptation; CL: Synthesize

103. 4. Systematic pain assessment is necessary for adequate pain management in the postoperative client. Guidelines from a variety of healthcare agencies and nursing groups recommend that institutions adopt a pain assessment scale to assist in facilitating pain management. Even though the client is receiving morphine sulfate by PCA, and the pump is working, the nurse should continue to assess the client. The concern is not to eliminate coughing but to control pain adequately. Coughing is necessary to prevent postoperative atelectasis and pneumonia. Breathing exercises may help control pain in some circumstances; however, most clients with thoracic surgery require parenteral opioid analgesics in the early postoperative period. Although it is necessary that the PCA device be checked periodically, reassuring the client is not sufficient, so further assessment is needed.

CN: Basic care and comfort; CL: Synthesize

104. 1. Because clients are discharged as soon as possible from the hospital, it is essential to evaluate the support they have to assist them with self-care at home. The distance the client lives from the hospital is not a critical factor in discharge planning. There are no data indicating that home blood pressure monitoring is needed. Knowledge of the causes of lung cancer, although important, is not the most essential area to evaluate given the client's postoperative status.

CN: Psychosocial adaptation; CL: Synthesize

105. 2. Epidermoid cancer involving the larger bronchi is almost entirely associated with heavy cigarette smoking. The American and Canadian Cancer Societies report that smoking is responsible for more than 80% of lung cancers in men and women. The prevalence of lung cancer is related to the duration and intensity of the smoking, so nurses can best prevent lung cancer by persuading clients to stop smoking. Chest radiographs aid in detection of lung cancer; they do not prevent it. Exposure to asbestos has been implicated as a risk factor for lung cancer, but cigarette smoking is the major risk factor. There are no data to support the use of home air filters in the prevention of lung cancer.

CN: Health promotion and maintenance; CL: Synthesize

106. 4. Deep breathing helps prevent microatelectasis and pneumonitis and also helps force air and fluid out of the pleural space into the chest tubes. More than half of the ventilatory process is accomplished by the rise and fall of the diaphragm. The diaphragm is the major muscle of respiration; deep breathing causes it to descend, not elevate, thereby increasing the ventilating surface. Deep breathing increases blood flow to the lungs; however, the primary reason for deep breathing is to expand alveoli and prevent atelectasis. The remaining lobe naturally hyperinflates to fill the space created by the resected lobe. This is an expected phenomenon.

CN: Physiological adaptation; CL: Evaluate

107. 2. It is essential that the nurse evaluate the effects of pain medication after the medication has had time to act; reassessment is necessary to determine the effectiveness of the pain management plan. Although it is prudent to check for discomfort related to positioning when assessing the

client's pain, repositioning the client immediately after administering pain medication is not necessary. Verbally reassuring the client after administering pain medication may be useful to help instill confidence in the treatment plan; however, it is not as important as evaluating the effectiveness of the medication. Readjusting the pain medication dosage as needed according to the client's condition is essential, but the effectiveness of the medication must be evaluated first.

CN: Physiological adaptation; CL: Synthesize

108. 3. This crackling sensation is subcutaneous emphysema.

Subcutaneous emphysema is not an unusual finding and is not dangerous if confined, and the nurse should mark the area to detect if the area is expanding. Progression can be serious, especially if the neck is involved; a tracheotomy may be needed at that point. If emphysema progresses noticeably in 1 hour, the **HCP**  should be notified. Lowering the head of the bed will not arrest the progress or provide any further information. A tracheotomy tray would be useful if subcutaneous emphysema progresses to the neck. Subcutaneous emphysema may progress if the chest drainage system does not adequately remove air and fluid; therefore, the system should not be turned off.

CN: Physiological adaptation; CL: Synthesize

109. 1. The recommended procedure for teaching clients postoperatively to deep breathe includes contracting (pulling in) the abdominal muscles and taking a slow, deep breath through the nose. This breath is held 3 to 5 seconds, which facilitates alveolar ventilation by improving the inspiratory phase of ventilation. Exhaling slowly as if trying to blow out a candle is a technique used in pursed-lip breathing to facilitate exhalation in clients with chronic obstructive pulmonary disease. It is recommended that the abdominal muscles be contracted, not relaxed, to promote deep breathing. The client should breathe through the nose.

CN: Physiological adaptation; CL: Synthesize

110. 3. A client who has undergone chest surgery should be taught to raise the arm on the affected side over the head to help prevent shoulder ankylosis. This exercise helps restore normal shoulder movement, prevents stiffening of

the shoulder joint, and improves muscle tone and power. Turning from side to side, raising and lowering the head, and flexing and extending the elbow on the affected side do not exercise the shoulder joint.

CN: Basic care and comfort; CL: Synthesize

111. 4. The drainage apparatus is always kept below the client's chest level to prevent backflow of fluid into the pleural space. The air vent must always be open in the closed chest drainage system to allow air from the client to escape. Stripping a chest tube causes excessive negative intrapleural pressure and is not recommended. Clamping a chest tube when moving a client is not recommended.

CN: Physiological adaptation; CL: Synthesize

112. 1. Cessation of fluid fluctuation in the tubing can mean one of several things: the lung has fully expanded and negative intrapleural pressure has been reestablished, the chest tube is occluded, or the chest tube is not in the pleural space. Fluid fluctuation occurs because during inspiration, intrapleural pressure exceeds the negative pressure generated in the water seal system. Therefore, drainage moves toward the client. During expiration, the pleural pressure exceeds that generated in the water seal system, and fluid moves away from the client. When the lung is collapsed or the chest tube is in the pleural space, fluid fluctuation is likely to be noted. The chest tube is not inserted in the mediastinal space.

CN: Physiological adaptation; CL: Analyze

113. 2. There should never be constant bubbling in the water seal system; normally, the bubbling is intermittent. Constant bubbling in the water seal bottle indicates an air leak, which means that less negative pressure is being exerted on the pleural space. Decreasing the suction will not reduce the leak. It is not necessary to notify the **HCP**  until the system has been checked and the problem identified.

CN: Physiological adaptation; CL: Synthesize

114. 1. In this case, there may be some obstruction to the flow of air and fluid out of the pleural space, causing air and fluid to collect and build up pressure. This prevents the remaining lung from reexpanding and can cause a

mediastinal shift to the opposite side. The nurse's first response is to assess the tubing for kinks or obstruction. Increasing the suction is not done without a **healthcare provider's**  prescription. The normal position of the drainage bottles is 2 to 3 feet (61 to 91.4 cm) below chest level. Clamping the tubes obstructs the flow of air and fluid out of the pleural space and should not be done.

 CN: Physiological adaptation; CL: Synthesize

115. 4. To promote chest tube drainage, the drainage system must be lower than the client's lungs. The amount of drainage is not abnormal; it is not necessary to notify the **HCP** . The nurse should chart the amount and color of drainage every 4 to 8 hours. The chest tube does not need to be clamped; the tubing connection is intact. There is sufficient water to maintain a water seal.

 CN: Physiological adaptation; CL: Synthesize

116. 3. A bottle of sterile water should be readily available and in view when a client has a chest tube so that the tube can be immediately submersed in the water if the chest tube system becomes disconnected. The chest tube should be reconnected to the water seal system as soon as a sterile functioning system can be reestablished. There is no need for a tracheostomy tray, another chest tube, or a spirometer to be placed at the bedside for emergency use.

 CN: Physiological adaptation; CL: Apply

117. 2. Gauze saturated with petrolatum is placed over the site to make an airtight seal to prevent air leakage during the healing process. Dry dressings or adhesive strips are not used. An airtight dressing is needed until the insertion site is healed.

 CN: Management of care; CL: Apply

The Client with Chest Trauma

118. 3. Respiratory distress or arrest is a universal finding of a tension pneumothorax. Unilateral, diminished, or absent breath sounds is a common finding. Tracheal deviation is an inconsistent and late finding. Muffled heart

sounds are suggestive of pericardial tamponade.

 CN: Physiological adaptation; CL: Analyze

119. 0.7 mL

$$10 \text{ mg} : X \text{ mL} = 15 \text{ mg} : 1 \text{ mL}$$

$$15 \text{ mg} \times X \text{ mL} = 10 \text{ mg} \times 1 \text{ mL}$$

$$15X = 10$$

$$X = 0.6667$$

$$X = 0.67 \text{ mL}$$

 CN: Pharmacological and parenteral therapies; CL: Apply

120. 2. Blunt chest trauma may lead to respiratory failure, and maintenance of adequate oxygenation is the priority for the client. Decreasing the client's anxiety is related to maintaining effective respirations and oxygenation. Although pain is distressing to the client and can increase anxiety and decrease respiratory effectiveness, pain control is secondary to maintaining oxygenation. Maintaining adequate circulatory volume is also secondary to maintaining adequate oxygenation.

 CN: Physiological adaptation; CL: Synthesize

121. 3. Fluctuation of fluid in the water seal column with respirations indicates that the system is functioning properly. If an obstruction were present in the chest tube, fluid fluctuation would be absent. Subcutaneous emphysema occurs when air pockets can be palpated beneath the client's skin around the chest tube insertion site. A leak in the system is indicated when continuous bubbling occurs in the water seal column.

 CN: Physiological adaptation; CL: Analyze

122. 4. Pneumothorax means that there is air in the pleural space causing pressure on the lung and the lung will collapse. The nurse will hear no sounds of air movement on auscultation. Movement of air through mucus produces crackles. Wheezing occurs when airways become obstructed. Dullness on percussion indicates increased density of lung tissue, usually caused by accumulation of fluid.

CN: Physiological adaptation; CL: Evaluate

123. 1. If the client reports no pain, then the objective of adequate pain relief has been met. Decreased anxiety is not related only to pain control; it could also be related to other factors. A respiratory rate of 26 breaths/min is not within normal limits, nor is the PaO₂ of 70 mm Hg (9.31 kPa), but these values are not measures of pain relief.

CN: Physiological adaptation; CL: Evaluate

124. 2. One unit of packed red blood cells is about 250 mL. If the blood is delivered at a rate of 60 mL/h, it will take about 4 hours to infuse the entire unit. The transfusion of a single unit of packed red blood cells should not exceed 4 hours to prevent the growth of bacteria and minimize the risk of septicemia.

CN: Pharmacological and parenteral therapies; CL: Apply

125. 2. Too rapid infusion of blood, or any intravenous fluid, can cause fluid volume overload and related problems such as pulmonary edema. Emboli formation, red blood cell hemolysis, and allergic reaction are not related to rapid infusion.

CN: Pharmacological and parenteral therapies; CL: Apply

126. 1. Pneumothorax signs and symptoms include sudden, sharp chest pain, tachypnea, and tachycardia. Other signs and symptoms include diminished or absent breath sounds over the affected lung, anxiety, and restlessness. Hemoptysis and cyanosis are not typically present with a moderate pneumothorax.

CN: Physiological adaptation; CL: Analyze

127. 4. A chest tube is inserted to reexpand the lung and remove air and

fluid. Oxygen is not administered through a chest tube. Chest tubes are not inserted to promote scar tissue formation. Antibiotics are not used to treat a pneumothorax.

 CN: Basic care and comfort; CL: Evaluate

128. The fluid typically localizes at the base of the thorax.

 CN: Management of care; CL: Synthesize

129. 1,2,3,4. Following a thoracentesis, the nurse should assess the client for possible complications of the procedure such as pneumothorax, tension pneumothorax, and subcutaneous emphysema, which can occur because of

the needle entering the chest cavity. Pulmonary edema could occur if a large volume was aspirated causing a significant mediastinal shift. Although infection is a possible complication, signs of infection will not be evident immediately after the procedure.

CN: Management of care; CL: Synthesize

130. 1. Cheyne-Stokes respiration is defined as a regular cycle that starts with normal breaths, which increase and then decrease followed by a period of apnea. It can be related to heart failure or a dysfunction of the respiratory center of the brain. Hyperventilation is associated with an increased rate and depth of respirations. Obstructive sleep apnea is recurring episodes of upper airway obstruction and reduced ventilation. Biot's respiration, also known as "cluster breathing," is periods of normal respirations followed by varying periods of apnea.

CN: Health promotion and maintenance; CL: Analyze

The Client with Acute Respiratory Distress Syndrome

131. 3,4,5. The prone position is used to improve oxygenation, ventilation, and perfusion. The importance of placing clients with ARDS in prone positioning should be explained to the family. The positioning allows for mobilization of secretions, and the nurse can provide suctioning. Clinical judgment must be used to determine the length of time in the prone position. If the client's hemodynamic status, oxygenation, or skin is compromised, the client should be returned to the supine position for evaluation. Facial edema is expected with the prone position, but the skin breakdown is of concern.

CN: Physiological adaptation; CL: Synthesize

132. 4. Prone positioning is used to improve oxygenation in clients with ARDS who are receiving mechanical ventilation. The positioning allows for recruitment of collapsed alveolar units, improvement in ventilation, reduction in shunting, mobilization of secretions, and improvement in functional reserve capacity (FRC). When the client is supine, side-to-side repositioning should be done every 2 hours with the head of the bed elevated at least 30 degrees.

CN: Physiological adaptation; CL: Synthesize

133. 1,4,5. Acute respiratory distress syndrome (ARDS) may cause renal failure and superinfection, so the nurse should monitor urine output and urine chemistries. Treatment of hypoxemia can be complicated because changes in lung tissue leave less pulmonary tissue available for gas exchange, thereby causing inadequate perfusion. Humidified oxygen may be one means of promoting oxygenation. The client has crackles in the lung bases, so the nurse should continue to assess breath sounds. Sedatives should be used with caution in clients with ARDS. The nurse should try other measures to relieve the client's restlessness and anxiety. The head of the bed should be elevated to 30 degrees to promote chest expansion and prevent atelectasis.

CN: Management of care; CL: Create

134. 4. One of the major risk factors for development of ARDS is hypovolemic shock. Adequate fluid replacement is essential to minimize the risk of ARDS in these clients. Teaching smoking cessation does not prevent ARDS. An abnormal serum potassium level and hypercapnia are not risk factors for ARDS.

CN: Physiological adaptation; CL: Synthesize

135. 2. A hallmark of early ARDS is refractory hypoxemia. The client's PaO₂ level continues to fall, despite higher concentrations of administered oxygen. Elevated carbon dioxide and metabolic acidosis occur late in the disorder. Severe electrolyte imbalances are not indicators of ARDS.

CN: Physiological adaptation; CL: Analyze

136. 2. The normal range for PaCO₂ is 35 to 45 mm Hg (4.7 to 6 kPa). Thus, this client's PaCO₂ level is low. The client is experiencing respiratory alkalosis (carbonic acid deficit) due to hyperventilation. The nurse should report this finding to the **healthcare provider (HCP)**  because it requires intervention. The increase in ventilation decreases the PaCO₂ level, which leads to decreased carbonic acid and alkalosis. The bicarbonate level is normal in uncompensated respiratory alkalosis along with the normal PaO₂ level. Normal serum pH is 7.35 to 7.45; in uncompensated respiratory

alkalosis, the serum pH is >7.45 .

CN: Reduction of risk potential; CL: Analyze

137. 1. The client may be fighting the ventilator breaths. Sedation is indicated to improve compliance with the ventilator in an attempt to lower peak inspiratory pressures. The workload of breathing does indicate the need for increased protein calories; however, this will not correct the respiratory problems with high pressures and respiratory rate. There is no indication that the client is experiencing pain. Increasing the rate on the ventilator is not indicated with the client's increased spontaneous rate.

CN: Physiological adaptation; CL: Synthesize

138. 1. Manifestations of adult respiratory distress syndrome (ARDS) secondary to acute pancreatitis include respiratory distress, tachypnea, dyspnea, fever, dry cough, fine crackles heard throughout lung fields, possible confusion and agitation, and hypoxemia with arterial oxygen level below 50 mm Hg. The nurse should report the arterial oxygen level of 46 mm Hg (6.1 kPa) to the **HCP** 📖. A respiratory rate of 12 is normal and not considered a sign of respiratory distress. Adventitious lung sounds, such as crackles, are typically found in clients with ARDS. Oxygen saturation of 96% is satisfactory and does not represent hypoxemia or low arterial oxygen saturation.

CN: Physiologic adaptation; CL: Synthesize

139. 1. Normal PaO_2 level ranges from 80 to 100 mm Hg (10.7 to 13.3 kPa). When PaO_2 falls to 50 mm Hg (6.7 kPa), the nurse should be alert for signs of hypoxia and impending respiratory failure. An oxygen level this low poses a severe risk for respiratory failure. The client will require oxygenation at a concentration that maintains the PaO_2 at 55 to 60 mm Hg (7.3 to 8 kPa) or more.

CN: Physiological adaptation; CL: Analyze

140. 3. Endotracheal intubation and mechanical ventilation are required in ARDS to maintain adequate respiratory support. Endotracheal intubation, not a tracheostomy, is usually the initial method of maintaining an airway. The

client requires mechanical ventilation; nasal oxygen will not provide adequate oxygenation. Chest tubes are used to remove air or fluid from intrapleural spaces.

 CN: Physiological adaptation; CL: Apply

141. 1. The two risk factors most commonly associated with the development of ARDS are gram-negative septic shock and gastric content aspiration. Nurses should be particularly vigilant in assessing a client for onset of ARDS if the client has experienced direct lung trauma or a systemic inflammatory response syndrome (which can be caused by any physiologic insult that leads to widespread inflammation). Chronic obstructive pulmonary disease, asthma, and heart failure are not direct causes of ARDS.

 CN: Reduction of risk potential; CL: Apply

142. 4. Auscultation for bilateral breath sounds is the most appropriate method for determining cuff placement. The nurse should also look for the symmetrical rise and fall of the chest and should note the location of the exit mark on the tube. Assessments of skin color, respiratory rate, and the amount of cuff inflation cannot validate the placement of the endotracheal tube.

 CN: Basic care and comfort; CL: Evaluate

143. 4. The nurse should suction the client if the client is not able to cough up secretions and clear the airway. Administering oxygen will not promote airway clearance. The client should be turned every 2 hours to help move secretions; every 4 hours is not often enough. Administering sedatives to promote rest is contraindicated in acute respiratory distress because sedatives can depress respirations.

 CN: Physiological adaptation; CL: Synthesize

144. 1. Gastrointestinal hemorrhage occurs in about 25% of clients receiving prolonged mechanical ventilation because of the development of stress ulcers. Clients who are receiving steroid therapy and those with a previous history of ulcers are most likely to be at risk. Other possible complications include incorrect ventilation, oxygen toxicity, fluid imbalance, decreased cardiac output, pneumothorax, infection, and atelectasis.

 CN: Physiological adaptation; CL: Analyze

Managing Care, Quality, and Safety of Clients with Respiratory Health Problems

145. 2. Respirations of 36 breaths/min and diminished wheezing are indicative of respiratory distress. This finding takes precedence over a client scheduled for an angiogram, a client with a heart rate of 90 bpm needing a scheduled beta-blocker, or a client with a PaO₂ of 56 mm Hg, which is indicated for a client being discharged home on oxygen.

CN: Management of care; CL: Synthesize

146. 1. UAP  can assist a client with the adjustment of his or her oxygen delivery device. Making adjustments based on client responses, monitoring for adverse effects, and assessing for the best methods of oxygen delivery are skills that require nursing judgments and can only be performed by a nurse.

CN: Management of care; CL: Analyze

147. 4. Confusion and vertigo are risk factors for falls. Measures must be taken to minimize the risk of injury. The nurse or UAP  should check on the client regularly to determine needs regarding elimination. Restraints, including bed rails and extremity restraints, should be used only to ensure the person's safety or the safety of others, and there must be a written prescription from a **healthcare provider (HCP)**  before using them. The nurse should never ask the roommate of a client to be responsible for the client's safety.

CN: Safety and infection control; CL: Synthesize

148. 4. Airborne precautions prevent transmission of infectious agents that remain infectious over long distances when suspended in the air (e.g., *Mycobacterium tuberculosis*, measles, varicella virus [chickenpox], and possibly SARS-CoV). The preferred placement is in an isolation single-client room that is equipped with special air handling and ventilation. A negative pressure room, or an area that exhausts room air directly outside or through HEPA filters, should be used if recirculation is unavoidable. While hand hygiene is important, it is not sufficient to prevent transmission of tuberculosis. Contact precautions are for clients with known or suspected

infections or evidence of syndromes that represent an increased risk for contact transmission. Droplet precautions are intended to prevent transmission of pathogens spread through close respiratory or mucous membrane contact with respiratory secretions. Because these pathogens do not remain infectious over long distances in a healthcare facility, special air handling and ventilation are not required to prevent droplet transmission.

CN: Safety and infection control; CL: Synthesize

149. 2,3,4,5. One of the “five rights” of drug administration is “right medication.” Cefazolin was not the medication prescribed. The pharmacist is the professional resource and serves as a check to ensure that clients receive the right medication. Returning unwanted medications to the pharmacy will decrease the opportunity for a medication error by the nurse who follows the current nurse.

CN: Safety and infection control; CL: Synthesize

150. 1,3,4,2. Because two major complications of endotracheal tube intubation, inadvertent extubation and aspiration, can be catastrophic events, assessment of this client is the first priority. Cellulitis is a serious infection as there is inflammation of subcutaneous tissues; third spacing of fluid may promote the formation of a fluid volume deficit, which can be exacerbated by the fever due to insensible fluid loss. The nurse should assess this client next to determine current vital signs and fluid status. The nurse should assess the client with the IV fluids next because the new bag of fluids will need to be hung in 30 to 40 minutes. IV therapy necessitates that the client be assessed for signs and symptoms of adequate hydration (moist mucous membranes, elastic skin turgor, vital signs within normal limits, adequate urine output, and level of consciousness within normal limits), and the IV access site needs to be assessed. From the information provided, there is no indication that the client who had the cerebrovascular accident is unstable. Thus, this client is the last **priority** for assessment.

CN: Management of care; CL: Synthesize

151. 1,2,3. The process of changing a healthcare system from an acute care model to a community-based care model uses continuous quality improvement (CQI) methods. The goal is to improve the health of chronically

ill clients. Areas for improvement include health systems, delivery system design, decision support, clinical information systems, self-management support, and the community. This system requires healthcare services that are client centered and coordinated among members of the healthcare team and the client and the family. These changes do not focus on the administrative leadership or the care in the acute care setting alone.

CN: Management of care; CL: Synthesize

152. 4. Several factors designate this client as a high fall risk based on the Morse Fall Scale: history of falling (25), secondary diagnosis (15), plus IV access (20). The client's total score is 60. There is also concern that the client's gait is at least weak if not impaired due to hospitalization for pneumonia, which may add to the client's fall risk. After evaluating the client's risk, the nurse must develop a plan and take action to maximize the client's safety.

CN: Safety and infection control; CL: Analyze

153. 1,2,3,4. Gloves, gown, surgical mask, and eye protection/glasses are worn to protect healthcare workers and to help prevent the spread of infection when clients are placed in droplet isolation. Because droplets are too heavy to be airborne, a respirator is not required when caring for a client in droplet precautions.

CN: Safety and infection control; CL: Apply

154. 3. The nurse has already called for help and established unresponsiveness, so the first action is to open the client's airway; opening the airway may result in spontaneous breathing and will help the nurse determine whether or not further intervention is required. Pushing the "code blue" button may not be the appropriate action if the client is breathing and becomes responsive once the airway is open. A quick assessment upon opening the client's airway will help the nurse to determine if the **rapid response team** is needed. Calling for a defibrillator may not be the necessary or appropriate action once the client's airway has been opened.

CN: Safety and infection control; CL: Synthesize

155. 2,3,1,4. The nurse should first assess the client's respiratory status to

determine if there is a physiological reason for the client's confusion. Other physiological factors to assess include pain and elimination. Safety needs including medication interactions should then be evaluated. Requesting restraints in order to maintain client safety should be used as a last resort.

CN: Safety and infection control; CL: Synthesize

156. 1,2,4,3. The elderly client with pneumonia, an elevated temperature, and shortness of breath is the most acutely ill client described and should be the client with the highest priority. The elevated temperature and the shortness of breath can lead to a decrease in the client's oxygen levels and can predispose the client to dehydration and confusion. Then the nurse should assess the client with the thoracotomy who is requesting pain medication and administer any needed medication. The client with emphysema should be the next priority so that the bronchodilator can be administered on schedule as close as possible. The nurse would then assess the client with suspected tuberculosis and a cough.

CN: Management of care; CL: Synthesize

157. 2,3,5. A client with pneumonia experiencing diaphoresis is at risk for dehydration and increased temperature and heart rate. The fluid status, intake, and urine output should be monitored closely. The client is febrile, causing an increase in heart rate. Fluid volume deficit may also increase the heart rate. The underlying cause of the tachycardia can be treated with acetaminophen and increased intake of fluids. Bed rest limits lung expansion, and sitting up and deep breathing should be encouraged in a client with pneumonia. The blood pressure is stable enough to allow the client to get out of bed to the chair, with assistance to ensure safety. It is not necessary to notify the **HCP**.

CN: Physiological adaptation; CL: Synthesize

The Client with Upper Gastrointestinal Tract Health Problems

- The Client with Disorders of the Oral Cavity
- The Client with Peptic Ulcer Disease
- The Client with Cancer of the Stomach
- The Client with Gastroesophageal Reflux Disease
- Managing Care, Quality, and Safety of Clients with Upper Gastrointestinal Tract Health Problems
- Answers, Rationales, and Test-Taking Strategies

The Client with Disorders of the Oral Cavity

1. A nurse is caring for a client who has just returned from surgery to treat a fractured mandible. The jaws are wired. Which items should always be available at this client's bedside? Select all that apply.

- ☐ 1. nasogastric tube
- ☐ 2. wire cutters
- ☐ 3. oxygen cannula
- ☐ 4. suction equipment
- ☐ 5. code cart

2. The nurse is teaching a client with stomatitis about mouth care. Which instruction is **most** appropriate?

- ☐ 1. Drink hot tea at frequent intervals.
- ☐ 2. Gargle with antiseptic mouthwash.
- ☐ 3. Use an electric toothbrush.
- ☐ 4. Eat a soft, bland diet.

3. A client who has a history of bacterial endocarditis is scheduled to have oral surgery to remove a tooth. What should the nurse instruct the client to do?

- ☐ 1. Gargle with a saline solution prior to the appointment.
- ☐ 2. Rinse the mouth with mouthwash the night before and day of the surgery.
- ☐ 3. Contact the health provider to request a sedative.
- ☐ 4. Be sure the dentist prescribes a prophylactic antibiotic prior to the oral surgery.

4. Amoxicillin trihydrate 300 mg PO has been prescribed for a client with an oral infection. The medication is available in a liquid suspension that is available as 250 mg/5 mL. How many milliliters should the nurse administer? Record your answer using a whole number.

mL.

5. During the assessment of a client's mouth, the nurse notes the absence of saliva. The client reports having pain behind the ear. The client has been nothing-by-mouth (NPO) for several days but now can have liquids. The nurse should:

- ☐ 1. request a prescription for an antifungal mouthwash.
- ☐ 2. instruct the client to brush the gums as well as the teeth.
- ☐ 3. encourage the client to suck on hard candy.
- ☐ 4. give the client a hydrogen peroxide-based mouthwash.

6. The nurse is preparing a community presentation on oral cancer. Which is a **primary** risk factor for oral cancer that the nurse should include in the presentation?

- ☐ 1. use of alcohol
- ☐ 2. frequent use of mouthwash
- ☐ 3. lack of vitamin B₁₂
- ☐ 4. lack of regular teeth cleaning by a dentist

7. A client has early signs of oral cancer. To conduct a focused assessment, what should the nurse do? Select all that apply.

- ☐ 1. inspect the mouth for infection and inflammation
- ☐ 2. inquire about loss of sense of taste
- ☐ 3. determine presence of dysphagia
- ☐ 4. monitor the client's height and weight
- ☐ 5. ask if the client is urinating regularly
- ☐ 6. monitor for frequent usage of narcotics

8. Following surgery to set a fractured mandible, the client has swelling at the surgery site. The **priority** for nursing care is to:

- ☐ 1. prevent nausea and vomiting.
- ☐ 2. maintain a patent airway.
- ☐ 3. provide frequent oral hygiene.
- ☐ 4. establish a way for the client to communicate.

9. A client who has had the jaws wired begins to vomit. The nurse should **first**:

- ☐ 1. insert a nasogastric (NG) tube and connect it to suction.
- ☐ 2. use wire cutters to cut the wire.
- ☐ 3. suction the client's airway as needed.
- ☐ 4. administer an antiemetic intravenously.

The Client with Peptic Ulcer Disease

10. A client is admitted to the hospital after vomiting bright red blood and is diagnosed with a bleeding duodenal ulcer. The client develops a sudden, sharp pain in the midepigastriac region along with a rigid, board-like abdomen. After obtaining the client's vital signs, what should the nurse do **next**?

- ☐ 1. Administer pain medication as prescribed.
- ☐ 2. Raise the head of the bed.
- ☐ 3. Prepare to insert a nasogastric tube.
- ☐ 4. Notify the healthcare provider (HCP).

11. When obtaining a nursing history from a client with a suspected gastric ulcer, which signs and symptoms should the nurse assess? Select all that apply.

- ☐ 1. epigastric pain at night
- ☐ 2. relief of epigastric pain after eating
- ☐ 3. vomiting
- ☐ 4. weight loss
- ☐ 5. melena

12. The nurse is caring for a client who has had a gastroscopy. Which findings indicate that the client is developing a complication related to the procedure? Select all that apply.

- ☐ 1. The client has a sore throat.
- ☐ 2. The client has a temperature of 100°F (37.8°C).
- ☐ 3. The client appears drowsy following the procedure.
- ☐ 4. The client has epigastric pain.
- ☐ 5. The client experiences hematemesis.

13. A client admitted to the hospital with peptic ulcer disease tells the nurse about having black, tarry stools. The nurse should:

- ☐ 1. encourage the client to increase fluid intake.
- ☐ 2. advise the client to avoid iron-rich foods.
- ☐ 3. place the client on contact precautions.
- ☐ 4. report the finding to the healthcare provider (HCP).

14. A client with peptic ulcer disease is taking ranitidine. What is the expected outcome of this drug?

- ☐ 1. heal the ulcer
- ☐ 2. protect the ulcer surface from acids
- ☐ 3. reduce acid concentration
- ☐ 4. limit gastric acid secretion

15. A client with a peptic ulcer reports epigastric pain that frequently causes the client to wake up during the night. The nurse should instruct the client to do which activities? Select all that apply.

- ☐ 1. Obtain adequate rest to reduce stimulation.
- ☐ 2. Eat small, frequent meals throughout the day.
- ☐ 3. Take all medications on time as prescribed.

- ☐ 4. Sit up for 1 hour when awakened at night.
- ☐ 5. Stay away from crowded areas.

16. A client with peptic ulcer disease reports being nauseated most of the day and now feeling light-headed and dizzy. Based upon these findings, which nursing actions would be **most** appropriate for the nurse to take? Select all that apply.

- ☐ 1. administering an antacid hourly until nausea subsides
- ☐ 2. monitoring the client's vital signs
- ☐ 3. notifying the healthcare provider (HCP) of the client's symptoms
- ☐ 4. initiating oxygen therapy
- ☐ 5. reassessing the client in an hour

17. The nurse is teaching a client with a peptic ulcer about the diet that should be followed after discharge. The nurse should explain that the diet should include:

- ☐ 1. bland foods.
- ☐ 2. high-protein foods.
- ☐ 3. any foods that are tolerated.
- ☐ 4. a glass of milk with each meal.

18. A client diagnosed with peptic ulcer disease (PUD) has an *H. pylori* infection. The client is following a 2-week drug regimen that includes clarithromycin along with omeprazole and amoxicillin. The nurse should instruct the client to:

- ☐ 1. alternate the use of the drugs.
- ☐ 2. take the drugs at different times during the day.
- ☐ 3. discontinue all drugs if nausea occurs.
- ☐ 4. take the drugs for the entire 2-week period.

19. A client with peptic ulcer disease (PUD) is admitted to the hospital for a gastric resection. The client reports a sudden sharp pain in the midepigastriac area that radiates to the shoulder. The nurse should **first**:

- ☐ 1. establish an IV line.
- ☐ 2. administer pain medication.
- ☐ 3. notify the surgeon.

- ☐ 4. call for a stat ECG.

20. A client is to take one daily dose of ranitidine at home to treat a peptic ulcer. The client understands proper drug administration of ranitidine when the client will take the drug:

- ☐ 1. before meals.
- ☐ 2. with meals.
- ☐ 3. at bedtime.
- ☐ 4. when pain occurs.

21. A client has been taking aluminum hydroxide 30 mL six times per day at home to treat a peptic ulcer. The client has been unable to have a bowel movement for 3 days. Based on this information, the nurse would determine that the **most** likely cause of the client's constipation is because the client:

- ☐ 1. has not been including enough fiber in the diet.
- ☐ 2. needs to increase the daily exercise.
- ☐ 3. is experiencing an adverse effect of the aluminum hydroxide.
- ☐ 4. has developed a gastrointestinal obstruction.

22. A client is taking an antacid for treatment of a peptic ulcer. Which statement **best** indicates that the client understands how to correctly take the antacid?

- ☐ 1. "I should take my antacid before I take my other medications."
- ☐ 2. "I need to decrease my intake of fluids so that I do not dilute the effects of my antacid."
- ☐ 3. "My antacid will be most effective if I take it whenever I experience stomach pains."
- ☐ 4. "It is best for me to take my antacid 1 to 3 hours after meals."

23. Which is an expected outcome for a client with peptic ulcer disease? The client will:

- ☐ 1. demonstrate appropriate use of analgesics to control pain.
- ☐ 2. explain the rationale for eliminating alcohol from the diet.
- ☐ 3. verbalize the importance of monitoring hemoglobin and hematocrit every 3 months.
- ☐ 4. eliminate engaging in contact sports.

The Client with Cancer of the Stomach

24. The nurse should assess the client who is being admitted to the hospital with upper GI bleeding for which finding? Select all that apply.

- ☐ 1. dry, flushed skin
- ☐ 2. decreased urine output
- ☐ 3. tachycardia
- ☐ 4. widening pulse pressure
- ☐ 5. rapid respirations
- ☐ 6. thirst

25. A client with cancer of the stomach had a total gastrectomy 2 days earlier. Which indicates the client is ready to try a liquid diet? The client:

- ☐ 1. is hungry.
- ☐ 2. has not requested pain medication for 8 hours.
- ☐ 3. has frequent bowel sounds.
- ☐ 4. has had a bowel movement.

26. Within 6 hours following a subtotal gastrectomy, the drainage from the client's NG tube is bright red. The nurse should **first**:

- ☐ 1. clamp the NG tube.
- ☐ 2. remove the existing NG tube.
- ☐ 3. irrigate the NG tube with iced saline.
- ☐ 4. chart the finding in the client's medical record.

27. A client has been diagnosed with adenocarcinoma of the stomach and is scheduled to undergo a subtotal gastrectomy (Billroth II procedure). During preoperative teaching, the nurse is reinforcing information about the surgical procedure. The nurse should instruct the client that the procedure will result in:

- ☐ 1. enlargement of the pyloric sphincter.
- ☐ 2. anastomosis of the gastric stump to the jejunum.
- ☐ 3. removal of the duodenum.
- ☐ 4. repositioning of the vagus nerve.

28. Since the diagnosis of stomach cancer, the client has been having

trouble sleeping and is frequently preoccupied with thoughts about how life will change. The client says, "I wish my life could stay the same." Based on this information, the nurse should understand that the client:

- ☐ 1. is having difficulty coping.
- ☐ 2. has a sleep disorder.
- ☐ 3. is grieving.
- ☐ 4. is anxious.

29. After a subtotal gastrectomy, the drainage in the nasogastric tube is expected to be what color for about 12 to 24 hours after surgery?

- ☐ 1. dark brown
- ☐ 2. bile green
- ☐ 3. bright red
- ☐ 4. cloudy white

30. Following a subtotal gastrectomy, a client has a nasogastric (NG) tube connected to low suction. The nurse should:

- ☐ 1. irrigate the tube with 30 mL of sterile water every hour, if needed.
- ☐ 2. reposition the tube if it is not draining well.
- ☐ 3. monitor the client for nausea, vomiting, and abdominal distention.
- ☐ 4. change to high suction if the drainage is sluggish on low suction.

31. A client who is recovering from gastric surgery is receiving IV fluids to be infused at 100 mL/h. The IV tubing delivers 15 gtt/mL. The nurse should infuse the solution at a flow rate of how many drops per minute to ensure that the client receives 100 mL/h? Record your answer using a whole number.

_____ gtt/min.

32. Following a gastrectomy, the nurse should place the client in which position?

- ☐ 1. prone
- ☐ 2. supine
- ☐ 3. low Fowler's
- ☐ 4. right or left Sims

33. To reduce the risk of dumping syndrome, the nurse should teach the client to:

- ☐ 1. sit upright for 30 minutes after meals.
- ☐ 2. drink liquids with meals, avoiding caffeine.
- ☐ 3. avoid milk and other dairy products.
- ☐ 4. decrease the carbohydrate content of meals.

34. A client who is recovering from a subtotal gastrectomy experiences dumping syndrome. The client asks the nurse, “When will I be able to eat three meals a day again like I used to?” Which response by the nurse is **most** appropriate?

- ☐ 1. “Eating six meals a day is time-consuming, isn’t it?”
- ☐ 2. “You will have to eat six small meals a day for the rest of your life.”
- ☐ 3. “You will be able to tolerate three meals a day before you are discharged.”
- ☐ 4. “Most clients can resume their normal meal patterns in about 6 to 12 months.”

35. After surgery for gastric cancer, a client is scheduled to undergo radiation therapy. The nurse should include which information in the teaching plan?

- ☐ 1. nutritional intake
- ☐ 2. management of alopecia
- ☐ 3. exercise and activity levels
- ☐ 4. access to community resources

36. One month following a subtotal gastrectomy for cancer, the nurse is evaluating the nursing care goal related to improved nutrition. What indicates that the client has attained the goal? The client has:

- ☐ 1. regained weight loss.
- ☐ 2. resumed normal dietary intake of three meals a day.
- ☐ 3. controlled nausea and vomiting through regular use of antiemetics.
- ☐ 4. achieved adequate nutritional status through oral or parenteral feedings.

The Client with Gastroesophageal Reflux Disease

37. Which instruction should the nurse include in the teaching plan for a client who is experiencing gastroesophageal reflux disease (GERD)?

- ☐ 1. Limit caffeine intake to two cups of coffee per day.
- ☐ 2. Do not lie down for 2 hours after eating.
- ☐ 3. Follow a low-protein diet.
- ☐ 4. Take medications with milk to decrease irritation.

38. The client is scheduled to have an upper gastrointestinal tract series of x-rays. Following the x-rays, the nurse should instruct the client to:

- ☐ 1. take a laxative.
- ☐ 2. follow a clear liquid diet.
- ☐ 3. administer an enema.
- ☐ 4. take an antiemetic.

39. A client who has been diagnosed with gastroesophageal reflux disease (GERD) has heartburn. To decrease the heartburn, the nurse should instruct the client to **eliminate** which item from the diet?

- ☐ 1. lean beef
- ☐ 2. air-popped popcorn
- ☐ 3. hot chocolate
- ☐ 4. raw vegetables

40. The client with gastroesophageal reflux disease (GERD) has a chronic cough. This symptom may indicate:

- ☐ 1. development of laryngeal cancer.
- ☐ 2. irritation of the esophagus.
- ☐ 3. esophageal scar tissue formation.
- ☐ 4. aspiration of gastric contents.

41. Bethanechol has been prescribed for a client with gastroesophageal reflux disease (GERD). The nurse should assess the client for which adverse effect?

- ☐ 1. constipation
- ☐ 2. urinary urgency
- ☐ 3. hypertension

- ☐ 4. dry oral mucosa

42. The nurse is developing a care management plan with a client who has been diagnosed with gastroesophageal reflux disease (GERD). What should the nurse instruct the client to do? Select all that apply.

- ☐ 1. Avoid a diet high in fatty foods.
- ☐ 2. Avoid beverages that contain caffeine.
- ☐ 3. Eat three meals a day, with the largest meal being at dinner in the evening.
- ☐ 4. Avoid all alcoholic beverages.
- ☐ 5. Lie down after consuming each meal for 30 minutes.
- ☐ 6. Use over-the-counter (OTC) antisecretory agents rather than prescriptions.

43. Which dietary measures would be useful in preventing esophageal reflux?

- ☐ 1. eating small, frequent meals
- ☐ 2. increasing fluid intake
- ☐ 3. avoiding air swallowing with meals
- ☐ 4. adding a bedtime snack to the dietary plan

44. The nurse is obtaining a health history from a client who has a sliding hiatal hernia associated with reflux. The nurse should ask the client about the presence of which symptom?

- ☐ 1. heartburn
- ☐ 2. jaundice
- ☐ 3. anorexia
- ☐ 4. stomatitis

45. Which risk factor would **most** likely contribute to the development of a hiatal hernia?

- ☐ 1. having a sedentary desk job
- ☐ 2. being 5 feet, 3 inches tall (160 cm) and weighing 190 lb (86.2 kg)
- ☐ 3. using laxatives frequently
- ☐ 4. being 40 years old

46. Which nursing interventions would **most** likely promote self-care behaviors in the client with a hiatal hernia?

- ☐ **1.** Introduce the client to other people who are successfully managing their care.
- ☐ **2.** Include the client's daughter in the teaching so that she can help implement the plan.
- ☐ **3.** Ask the client to identify other situations in which the client changed healthcare habits.
- ☐ **4.** Provide reassurance that the client will be able to implement all aspects of the plan successfully.

47. The client has been taking magnesium hydroxide (milk of magnesia) to control hiatal hernia symptoms. The nurse should assess the client for which condition most commonly associated with the ongoing use of magnesium-based antacids?

- ☐ **1.** anorexia
- ☐ **2.** weight gain
- ☐ **3.** diarrhea
- ☐ **4.** constipation

48. Which lifestyle modification should the nurse encourage the client with a hiatal hernia to include in activities of daily living?

- ☐ **1.** daily aerobic exercise
- ☐ **2.** eliminating smoking and alcohol use
- ☐ **3.** balancing activity and rest
- ☐ **4.** avoiding high-stress situations

49. In developing a teaching plan for the client with a hiatal hernia, the nurse's assessment of which work-related factors would be **most** useful?

- ☐ **1.** number and length of breaks
- ☐ **2.** body mechanics used in lifting
- ☐ **3.** temperature in the work area
- ☐ **4.** cleaning solvents used

50. The nurse instructs the client on health maintenance activities to help control symptoms from a hiatal hernia. Which statement would indicate that

the client has understood the instructions?

- ☐ 1. "I will avoid lying down after a meal."
- ☐ 2. "I can still enjoy my potato chips and cola at bedtime."
- ☐ 3. "I wish I did not have to give up swimming."
- ☐ 4. "If I wear a girdle, I will have more support for my stomach."

51. The nurse should instruct the client to avoid which drug while taking metoclopramide hydrochloride?

- ☐ 1. antacids
- ☐ 2. antihypertensives
- ☐ 3. anticoagulants
- ☐ 4. alcohol

52. A client is taking cimetidine to treat a hiatal hernia. The nurse should evaluate the client to determine that the drug has been effective in preventing which health problem?

- ☐ 1. esophageal reflux
- ☐ 2. dysphagia
- ☐ 3. esophagitis
- ☐ 4. ulcer formation

53. The client asks the nurse if surgery is needed to correct a hiatal hernia. Which reply by the nurse would be **most** accurate?

- ☐ 1. "Surgery is usually required, although medical treatment is attempted first."
- ☐ 2. "Hiatal hernia symptoms can usually be successfully managed with diet modifications, medications, and lifestyle changes."
- ☐ 3. "Surgery is not performed for this type of hernia."
- ☐ 4. "A minor surgical procedure to reduce the size of the diaphragmatic opening will probably be planned."

Managing Care, Quality, and Safety of Clients with Upper Gastrointestinal Tract Health Problems

54. A client has returned from surgery during which the jaws were wired

as treatment for a fractured mandible. The client is in stable condition. The nurse is instructing the unlicensed assistive personnel (UAP) on how to properly position the client. Which instructions about positioning would be appropriate for the nurse to give the UAP?

- ☐ 1. Keep the client in a side-lying position with the head slightly elevated.
- ☐ 2. Do not reposition the client without the assistance of a registered nurse (RN).
- ☐ 3. The client can assume any position that is comfortable.
- ☐ 4. Keep the client's head elevated on two pillows at all times.

55. The nurse has been assigned to provide care for four clients. In what order, from first to last, should the nurse assess these clients? All options must be used.

1. a client awaiting surgery for a hiatal hernia repair at 1100

2. a client with suspected gastric cancer who is on nothing-by-mouth (NPO) status for tests

3. a client with peptic ulcer disease experiencing a sudden onset of acute stomach pain

4. a client who is requesting pain medication 2 days after surgery to repair a fractured jaw

56. The nurse is caring for a client who has just had an upper GI

endoscopy. The client's vital signs must be taken every 30 minutes for 2 hours after the procedure. The nurse assigns an unlicensed assistive personnel (UAP) to take the vital signs. One hour later, the UAP reports the client, who was previously afebrile, has developed a temperature of 101.8°F (38.8°C). The nurse should:

- ☐ 1. promptly assess the client for potential perforation.
- ☐ 2. tell the assistant to change thermometers and retake the temperature.
- ☐ 3. plan to give the client acetaminophen to lower the temperature.
- ☐ 4. ask the UAP to bathe the client with tepid water.

57. Which hospitalized client is at risk to develop parotitis?

- ☐ 1. a 50-year-old client with nausea and vomiting who is on nothing-by-mouth status
- ☐ 2. a 75-year-old client with diabetes who has ill-fitting dentures
- ☐ 3. an 80-year-old client who has poor oral hygiene and is dehydrated
- ☐ 4. a 65-year-old client with lung cancer who has a feeding tube in place

58. The nurse instructs the unlicensed assistive personnel (UAP) on how to provide oral hygiene for clients who cannot perform this task for themselves. Which technique should the nurse ask the UAP to incorporate into the client's daily care?

- ☐ 1. Assess the oral cavity each time mouth care is given and record observations.
- ☐ 2. Use a soft toothbrush to brush the client's teeth after each meal.
- ☐ 3. Swab the client's tongue, gums, and lips with a soft foam applicator every 2 hours.
- ☐ 4. Rinse the client's mouth with mouthwash several times a day.

59. The nurse is developing standards of care for a client with gastroesophageal reflux disease and wants to review current evidence for practice. Which resource will provide the **most** helpful information?

- ☐ 1. a review in the Cochrane Library
- ☐ 2. a literature search in a database, such as the Cumulative Index to Nursing and Allied Health Literature (CINAHL)
- ☐ 3. an online nursing textbook

- ☐ 4. the policy and procedure manual at the healthcare agency

60. The nurse in the intensive care unit is giving a report to the nurse in the postsurgical unit about a client who had a gastrectomy. The **most** effective way to assure essential information about the client is reported is to:

- ☐ 1. give the report face to face with both nurses in a quiet room.
- ☐ 2. audiotape the report for future reference and documentation.
- ☐ 3. use a checklist with information individualized for the client.
- ☐ 4. document essential transfer information in the client's electronic health record.

61. A nurse is delegating activities to unlicensed assistive personnel (UAP). Which activities can be appropriately delegated? Select all that apply.

- ☐ 1. Assist client with oral care prior to breakfast.
- ☐ 2. Ask about location, quality, and radiation of pain.
- ☐ 3. Observe and document effect of medication after given by the nurse.
- ☐ 4. Measure and record intake and output throughout the shift.
- ☐ 5. Determine if client is oriented to person, place, and time and report to nurse.
- ☐ 6. Change a simple dry dressing on a client's coccyx while bathing.

Answers, Rationales, and Test-Taking Strategies

The answers and rationales for each question follow below, along with keys () to the client need (CN) and cognitive level (CL) for each question. In addition, you will also see a glossary icon () highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 12–23 and pages 35–36 in Part 1 of this book.

The Client with Disorders of the Oral Cavity

1. 2,4. Following surgery for a fractured mandible, the client's jaws will be wired. The nurse should be prepared to intervene quickly in case the client develops respiratory distress or begins to choke or vomit. Wire cutters or scissors should always be available in case the wires need to be cut in a medical emergency. Suction equipment should be available to help clear the client's airway if necessary. It is not necessary to keep a nasogastric tube or oxygen cannula at the client's bedside. Cardiopulmonary arrest is unlikely, so a code cart is not needed at the bedside.

CN: Safety and infection control; CL: Apply

2. 4. Clients with stomatitis (inflammation of the mouth) have significant discomfort, which impacts their ability to eat and drink. They will be most comfortable eating soft, bland foods and avoiding temperature extremes in their food and liquids. Gargling with an antiseptic mouthwash will be irritating to the mucosa. Mouth care should include gentle brushing with a soft toothbrush and flossing.

CN: Basic care and comfort; CL: Synthesize

3. 4. Clients who are at risk for developing infective endocarditis due to cardiac conditions such as a history of bacterial endocarditis must take prophylactic antibiotics before any dental procedure that may cause bleeding. Gargling with saline or using mouthwash is not sufficient to prevent infection. The client will not need a sedative prior to the surgery.

CN: Reduction of risk potential; CL: Synthesize

4. 6 mL. To administer 300 mg PO, the nurse will need to administer 6 mL. The following formula is used to calculate the correct dosage:

CN: Pharmacological and parenteral therapies; CL: Apply

5. 3. The lack of saliva, pain near the area of the ear, and the prolonged NPO status of the client are indications that the client may be developing parotitis, or inflammation of the parotid gland. Parotitis usually develops with dehydration combined with poor oral hygiene or when clients have been NPO for an extended period. Preventive measures include the use of sugarless hard candy or gum to stimulate saliva production, adequate hydration, and frequent mouth care. The client does not have indications of stomatitis

(inflammation of the mouth), which produces excessive salivation and a sore mouth. The client does not have indications of oral candidiasis (thrush), which causes bluish white mouth lesions, and the nurse does not need to request a prescription for an antifungal mouthwash. There are no indications that the client has gingivitis, which can be recognized by the inflamed gingiva and bleeding that occur during toothbrushing, and while the client should brush the teeth and gums, increasing salivation to prevent parotitis is the priority at this time.

CN: Basic care and comfort; CL: Synthesize

6. 1. Chronic and excessive use of alcohol can lead to oral cancer.

Smoking and use of smokeless tobacco are other significant risk factors. Additional risk factors include chronic irritation such as a broken tooth or ill-fitting dentures, poor dental hygiene, overexposure to sun (lip cancer), and syphilis. Use of mouthwash, lack of vitamin B₁₂, and lack of regular teeth cleaning appointments have not been implicated as primary risk factors for oral cancer.

CN: Health promotion and maintenance; CL: Analyze

7. 1,3,4. The nurse is conducting a focused assessment of the client's mouth and ability to obtain nutrition. Therefore, the nurse focuses on inspecting the mouth for infection or inflammation, determining if the client has difficulty swallowing, and assuring nutrition by weighing the client and noting weight loss or gain. A sign of oral cancer is numbness of the tongue; losing a sense of taste is not an early sign of oral cancer. Urinary output, while important, is not a part of a focused assessment for this health problem. The client may have pain, and for a more general assessment, the nurse can inquire about use of pain medications.

CN: Reduction of risk potential; CL: Synthesize

8. 2. The priority of care in the immediate postoperative phase is to maintain a patent airway. The nurse should observe the client carefully for signs of respiratory distress. If the client becomes nauseated, antiemetics should be administered to decrease the chance of vomiting with obstruction of the airway and aspiration of vomitus. Providing frequent oral hygiene and an alternative means of communication are important aspects of nursing care,

but maintaining a patent airway is most important.

CN: Physiological adaptation; CL: Synthesize

9. 3. The nurse's first action is to clear the client's airway as necessary. Inserting an NG tube or administering an antiemetic may prevent future vomiting episodes, but these procedures are not helpful when the client is actually vomiting. Cutting the wires is done only as a last resort or in case of respiratory or cardiac arrest.

CN: Physiological adaptation; CL: Synthesize

The Client with Peptic Ulcer Disease

10. 4. The client is experiencing a perforation of the ulcer, and the nurse should notify the HCP immediately. The body reacts to perforation of an ulcer by immobilizing the area as much as possible. This results in board-like abdominal rigidity, usually with extreme pain. Perforation is a medical emergency requiring immediate surgical intervention because peritonitis develops quickly after perforation. Administering pain medication is not the first action, although the nurse later should institute measures to relieve pain. Elevating the head of the bed will not minimize the perforation. A nasogastric tube may be used following surgery.

CN: Physiological adaptation; CL: Synthesize

11. 3,4,5. Vomiting and weight loss are common with gastric ulcers. The client may also have blood in the stools (melena) from gastric bleeding. Clients with a gastric ulcer are most likely to have a burning epigastric pain that occurs about 1 hour after eating. Eating frequently aggravates the pain. Clients with duodenal ulcers are more likely to have pain that occurs during the night and is frequently relieved by eating.

CN: Physiological adaptation; CL: Analyze

12. 2,4,5. Following a gastroscopy, the nurse should monitor the client for complications, which include perforation and the potential for aspiration. An elevated temperature, epigastric pain, or the vomiting of blood (hematemesis) are all indications of a possible perforation and should be reported promptly. A sore throat is a common occurrence following a gastroscopy. Clients are

usually sedated to decrease anxiety, and the nurse would anticipate that the client will be drowsy following the procedure.

CN: Reduction of risk potential; CL: Analyze

13. 4. Black, tarry stools are an important warning sign of bleeding in peptic ulcer disease. Digested blood in the stool causes it to be black; the odor of the stool is very offensive. The nurse should instruct the client to report the incidence of black stools promptly to the HCP. Increasing fluids or avoiding iron-rich foods will not change the stool color or consistency if the stools contain digested blood. Until other information is available, it is not necessary to initiate contact precautions.

CN: Reduction of risk potential; CL: Synthesize

14. 4. Histamine-2 (H₂) receptor antagonists, such as ranitidine, reduce gastric acid secretion. Antisecretories, or proton pump inhibitors, such as omeprazole, help ulcers heal quickly in 4 to 8 weeks. Cytoprotective drugs, such as sucralfate, protect the ulcer surface against acid, bile, and pepsin. Antacids reduce acid concentration and help reduce symptoms.

CN: Pharmacological and parenteral therapies; CL: Evaluate

15. 1,2,3,4. The nurse should encourage the client to reduce stimulation that may enhance gastric secretion. The nurse can also advise the client to utilize health practices that will prevent recurrences of ulcer pain, such as avoiding fatigue and elimination of smoking. Eating small, frequent meals helps to prevent gastric distention if not actively bleeding and decreases distention and release of gastrin. Medications should be administered promptly to maintain optimum levels. After awakening during the night, the client should eat a small snack and return to bed, keeping the head of the bed elevated for an hour after eating. It is not necessary to stay away from crowded areas.

CN: Physiological adaptation; CL: Synthesize

16. 2,3. The symptoms of nausea and dizziness in a client with peptic ulcer disease may be indicative of hemorrhage and should not be ignored. The appropriate nursing actions at this time are for the nurse to monitor the client's vital signs and notify the HCP of the client's symptoms. To

administer an antacid hourly or to wait 1 hour to reassess the client would be inappropriate; prompt intervention is essential in a client who is potentially experiencing a gastrointestinal hemorrhage. The nurse would notify the HCP of assessment findings and then initiate oxygen therapy if prescribed by the HCP.

CN: Physiological adaptation; CL: Synthesize

17. 3. Diet therapy for ulcer disease is a controversial issue. There is no scientific evidence that diet therapy promotes healing. Most clients are instructed to follow a diet that they can tolerate. There is no need for the client to ingest only a bland or high-protein diet. Milk may be included in the diet, but it is not recommended in excessive amounts.

CN: Basic care and comfort; CL: Apply

18. 4. The use of the triple-therapy approach to the *H. pylori* infection has proved effective; therefore, the nurse advises the client to take the drugs as prescribed for the duration of the prescription. The nurse instructs the client to avoid alternating the use of the drugs and to take all medication at the same time, three times a day unless otherwise noted by the **healthcare provider (HCP)** . Drugs have very few side effects; however, the nurse instructs the client to continue taking medications and contact the HCP if adverse effects occur.

CN: Pharmacological and parenteral therapies; CL: Synthesize

19. 3. The sharp, sudden midepigastric pain indicates the client may have a perforated ulcer. The nurse notifies the surgeon and may then obtain prescriptions for pain medication and IV fluids. It is not necessary to first obtain an ECG because the pain from ulcer perforation is different from that of chest pain that may indicate coronary artery syndrome (crushing pain radiating to the jaw).

CN: Physiological adaptation; CL: Synthesize

20. 3. Ranitidine blocks secretion of hydrochloric acid. Clients who take only one daily dose of ranitidine are usually advised to take it at bedtime to inhibit nocturnal secretion of acid. Clients who take the drug twice a day are advised to take it in the morning and at bedtime. It is not necessary to take the

drug before meals. The client should take the drug regularly, not just when pain occurs.

CN: Pharmacological and parenteral therapies; CL: Evaluate

21. 3. It is most likely that the client is experiencing an adverse effect of the antacid. Antacids with aluminum salt products, such as aluminum hydroxide, form insoluble salts in the body. These precipitate and accumulate in the intestines, causing constipation. Increasing dietary fiber intake or daily exercise may be a beneficial lifestyle change for the client but is not likely to relieve the constipation caused by the aluminum hydroxide. Constipation, in isolation from other symptoms, is not a sign of a bowel obstruction.

CN: Pharmacological and parenteral therapies; CL: Analyze

22. 4. Antacids are most effective if taken 1 to 3 hours after meals and at bedtime. When an antacid is taken on an empty stomach, the duration of the drug's action is greatly decreased. Taking antacids 1 to 3 hours after a meal lengthens the duration of action, thus increasing the therapeutic action of the drug. Antacids should be administered about 2 hours after other medications to decrease the chance of drug interactions. It is not necessary to decrease fluid intake when taking antacids. If antacids are taken more frequently than recommended, the likelihood of developing adverse effects increases. Therefore, the client should not take antacids as often as desired to control pain.

CN: Pharmacological and parenteral therapies; CL: Evaluate

23. 2. Alcohol is a gastric irritant that should be eliminated from the intake of the client with peptic ulcer disease. Analgesics are not used to control ulcer pain; many analgesics are gastric irritants. The client's hemoglobin and hematocrit typically do not need to be monitored every 3 months, unless gastrointestinal bleeding is suspected. The client can maintain an active lifestyle and does not need to eliminate contact sports as long as they are not stress inducing.

CN: Reduction of risk potential; CL: Evaluate

The Client with Cancer of the Stomach

24. 2,3,5,6. The client who is experiencing upper GI bleeding is at risk for developing hypovolemic shock from blood loss. Therefore, the signs and symptoms the nurse should expect to find are those related to hypovolemia, including decreased urine output, tachycardia, rapid respirations, and thirst. The client's skin would be cool and clammy, not dry, and flushed. The client would also be likely to develop hypotension, which would lead to a narrowing pulse pressure, not a widening pulse pressure.

CN: Physiological adaptation; CL: Analyze

25. 3. The client can begin eating with a liquid diet when bowel sounds return, usually in 2 to 3 days. The client may be hungry but cannot have oral fluids or foods until intestinal motility has been established. The client may continue to have postoperative pain for several days; because receiving a liquid diet does not depend on the client being pain free, the nurse can continue to offer pain medication. The client does not have to experience a bowel movement to receive fluids and food.

CN: Physiological adaptation; CL: Synthesize

26. 4. NG drainage is expected to be bright red during the first 12 hours after surgery and then darken within 24 hours. The nurse notes the color of the drainage on the **medical record**  and then monitors the change of color of the drainage throughout the immediate postoperative period. To prevent stress on the suture line, NG suction is applied and patency of the tube maintained. Removal of the NG tube may traumatize the surgical site. The NG tube is irrigated only if the **healthcare provider (HCP)**  prescribes irrigation because there is danger of injury to the suture line; saline at room temperature is usually prescribed.

CN: Physiological adaptation; CL: Synthesize

27. 2. A Billroth II procedure bypasses the duodenum and connects the gastric stump directly to the jejunum. The pyloric sphincter is removed, along with some of the stomach fundus.

CN: Physiological adaptation; CL: Apply

28. 3. The information presented indicates the client is grieving about the changes that will occur as a result of the diagnosis of gastric cancer. The

information does not indicate the client is having difficulty coping or experiencing insomnia. The client is not demonstrating signs of anxiety.

 CN: Psychosocial adaptation; CL: Analyze

29. 1. About 12 to 24 hours after a subtotal gastrectomy, gastric drainage is normally brown, which indicates digested blood. Bile green or cloudy white drainage is not expected during the first 12 to 24 hours after a subtotal gastrectomy. Drainage during the first 6 to 12 hours contains some bright red blood, but large amounts of blood or excessive bloody drainage should be reported to the **healthcare provider (HCP)**  promptly.

 CN: Reduction of risk potential; CL: Apply

30. 3. Nausea, vomiting, or abdominal distention indicates that gas and secretions are accumulating within the gastric pouch due to impaired peristalsis or edema at the operative site and may indicate that the drainage system is not working properly. Saline is used to irrigate NG tubes. Hypotonic solutions such as water increase electrolyte loss. In addition, a **healthcare provider's (HCP)**  prescription is needed to irrigate the NG tube because this procedure could disrupt the suture line. After gastric surgery, only the surgeon repositions the NG tube because of the danger of rupturing or dislodging the suture line. The amount of suction varies with the type of tube used and is prescribed by the HCP. High suction may create too much tension on the gastric suture line.

 CN: Reduction of risk potential; CL: Synthesize

31. 25 gtt/min. To administer IV fluids at 100 mL/h using tubing that has a drip factor of 15 gtt/mL, the nurse should use the following formula: $100 \text{ mL}/60 \text{ minutes} \times 15 \text{ gtt}/1 \text{ mL} = 25 \text{ gtt}/\text{min}$.

 CN: Pharmacological and parenteral therapies; CL: Apply

32. 3. A client who has had abdominal surgery is best placed in a low Fowler's position postoperatively. This positioning relaxes abdominal muscles and provides for maximum respiratory and cardiovascular function. The prone, supine, or Sims position would not be tolerated by a client who has had abdominal surgery, nor do those positions support respiratory or cardiovascular functioning.

CN: Physiological adaptation; CL: Synthesize

33. 4. Carbohydrates are restricted, but protein, including meat and dairy products, is recommended because it is digested more slowly. Lying down for 30 minutes after a meal is encouraged to slow movement of the food bolus. Fluids are restricted to reduce the bulk of food. There is no need to avoid caffeine.

CN: Basic care and comfort; CL: Synthesize

34. 4. The symptoms related to dumping syndrome that occur after a gastrectomy usually disappear by 6 to 12 months after surgery. Most clients can begin to resume normal meal patterns after signs of the dumping syndrome have stopped. Acknowledging that eating six meals a day is time-consuming does not address the client's question and makes an assumption about the client's concerns. It is not necessarily true that a six-meal-a-day dietary pattern will be required for the rest of the client's life. Clients will not be able to eat three meals a day before hospital discharge.

CN: Physiological adaptation; CL: Synthesize

35. 1. Clients who have had gastric surgery are prone to postoperative complications, such as dumping syndrome and postprandial hypoglycemia, which can affect nutritional intake. Vitamin absorption can also be an issue, depending on the extent of the gastric surgery. Radiation therapy to the upper gastrointestinal area also can affect nutritional intake by causing anorexia, nausea, and esophagitis. The client would not be expected to develop alopecia. Exercise and activity levels as well as access to community resources are important teaching areas, but nutritional intake is a priority need.

CN: Reduction of risk potential; CL: Synthesize

36. 4. An appropriate expected outcome is for the client to achieve optimal nutritional status through the use of oral feedings or total parenteral nutrition (TPN). TPN may be used to supplement oral intake, or it may be used alone if the client cannot tolerate oral feedings. The client would not be expected to regain lost weight within 1 month after surgery or to tolerate a normal dietary intake of three meals a day. Nausea and vomiting would not be considered an

expected outcome of gastric surgery, and regular use of antiemetics would not be anticipated.

CN: Physiological adaptation; CL: Evaluate

The Client with Gastroesophageal Reflux Disease

37. 2. The nurse should instruct the client to not lie down for about 2 hours after eating to prevent reflux. Caffeinated beverages decrease pressure in the lower esophageal sphincter, and milk increases gastric acid secretion, so these beverages should be avoided. The client is encouraged to follow a high-protein, low-fat diet and avoid foods that are irritating.

CN: Reduction of risk potential; CL: Synthesize

38. 1. The client should take a laxative after an upper gastrointestinal series to stimulate a bowel movement. This examination involves the administration of barium, which must be promptly eliminated from the body because it may harden and cause an obstruction. A clear liquid diet would have no effect on stimulating removal of the barium. The client should not have nausea, and an antiemetic would not be necessary; additionally, the antiemetic will decrease peristalsis and increase the likelihood of eliminating the barium. An enema would be ineffective because the barium is too high in the gastrointestinal tract.

CN: Reduction of risk potential; CL: Synthesize

39. 3. With GERD, eating substances that decrease lower esophageal sphincter pressure causes heartburn. A decrease in the lower esophageal sphincter pressure allows gastric contents to reflux into the lower end of the esophagus. Foods that can cause a decrease in esophageal sphincter pressure include fatty foods, chocolate, caffeinated beverages, peppermint, and alcohol. A diet high in protein and low in fat is recommended for clients with GERD. Lean beef, popcorn, and raw vegetables would be acceptable.

CN: Physiological adaptation; CL: Synthesize

40. 4. Clients with GERD can develop pulmonary symptoms, such as coughing, wheezing, and dyspnea, that are caused by the aspiration of gastric contents. GERD does not predispose the client to the development of

laryngeal cancer. Irritation of the esophagus and esophageal scar tissue formation can develop as a result of GERD. However, GERD is more likely to cause painful and difficult swallowing.

CN: Physiological adaptation; CL: Analyze

41. 2. Bethanechol, a cholinergic drug, may be used in GERD to increase lower esophageal sphincter pressure and facilitate gastric emptying. Cholinergic adverse effects may include urinary urgency, diarrhea, abdominal cramping, hypotension, and increased salivation. To avoid these adverse effects, the client should be closely monitored to establish the minimum effective dose.

CN: Pharmacological and parenteral therapies; CL: Analyze

42. 1,2,4. No specific diet is necessary, but foods that cause reflux are avoided, including fatty foods (which decrease the rate of gastric emptying) and foods that decrease lower esophageal sphincter (LES) pressure such as chocolate, peppermint, coffee, and tea. The client should also avoid alcohol. The client should not lie down for 3 to 4 hours after eating. Antisecretory agents decrease the secretion of hydrochloric acid (HCl) by the stomach; some are available in both OTC and prescription formulations, but the OTC preparations have lower drug dosages compared with prescription drugs. Cimetidine, ranitidine, famotidine, and nizatidine are available in both formulations.

CN: Physiological adaptation; CL: Synthesize

43. 1. Esophageal reflux worsens when the stomach is overdistended with food. Therefore, an important measure is to eat small, frequent meals. Fluid intake should be decreased during meals to reduce abdominal distention. Avoiding air swallowing does not prevent esophageal reflux. Food intake in the evening should be strictly limited to reduce the incidence of nighttime reflux, so bedtime snacks are not recommended.

CN: Basic care and comfort; CL: Synthesize

44. 1. Heartburn, the most common symptom of a sliding hiatal hernia, results from reflux of gastric secretions into the esophagus. Regurgitation of gastric contents and dysphagia are other common symptoms. Jaundice, which

results from a high concentration of bilirubin in the blood, is not associated with hiatal hernia. Anorexia is not a typical symptom of hiatal hernia. Stomatitis is inflammation of the mouth.

 CN: Physiological adaptation; CL: Analyze

45. 2. Any factor that increases intra-abdominal pressure, such as obesity, can contribute to the development of hiatal hernia. Other factors include abdominal straining, frequent heavy lifting, and pregnancy. Hiatal hernia is also associated with older age and occurs in women more frequently than in men. Having a sedentary desk job, using laxatives frequently, or being 40 years old is not likely to be a contributing factor in development of a hiatal hernia.

 CN: Reduction of risk potential; CL: Analyze

46. 3. Self-responsibility is the key to individual health maintenance. Using examples of situations in which the client has demonstrated self-responsibility can be reinforcing and supporting. The client has ultimate responsibility for personal health habits. Meeting other people who are managing their care and involving family members can be helpful, but individual motivation is more important. Reassurance can be helpful but is less important than individualization of care.

 CN: Basic care and comfort; CL: Synthesize

47. 3. The magnesium salts in magnesium hydroxide are related to those found in laxatives and may cause diarrhea. Aluminum salt products can cause constipation. Many clients find that a combination product is required to maintain normal bowel elimination. The use of magnesium hydroxide does not cause anorexia or weight gain.

 CN: Pharmacological and parenteral therapies; CL: Analyze

48. 2. Smoking and alcohol use both reduce esophageal sphincter tone and can result in reflux. They therefore should be avoided by clients with hiatal hernia. Daily aerobic exercise, balancing activity and rest, and avoiding high-stress situations may increase the client's general health and well-being, but they are not directly associated with hiatal hernia.

 CN: Health promotion and maintenance; CL: Synthesize

49. 2. Bending, especially after eating, can cause gastroesophageal reflux. Lifting heavy objects increases intra-abdominal pressure. Assessing the client's lifting techniques enables the nurse to evaluate the client's knowledge of factors contributing to hiatal hernia and how to prevent complications. Number and length of breaks, temperature in the work area, and cleaning solvents used are not directly related to treatment of hiatal hernia.

CN: Basic care and comfort; CL: Create

50. 1. A client with a hiatal hernia should avoid the recumbent position immediately after meals to minimize gastric reflux. Bedtime snacks, as well as high-fat foods and carbonated beverages, should be avoided. Excessive vigorous exercise also should be avoided, especially after meals, but there is no reason why the client must give up swimming. Wearing tight, constrictive clothing such as a girdle can increase intra-abdominal pressure and thus lead to reflux of gastric juices.

CN: Basic care and comfort; CL: Evaluate

51. 4. Metoclopramide hydrochloride can cause sedation. Alcohol and other central nervous system depressants add to this sedation. A client who is taking this drug should be cautioned to avoid driving or performing other hazardous activities for a few hours after taking the drug. Clients may take antacids, antihypertensives, and anticoagulants while on metoclopramide.

CN: Pharmacological and parenteral therapies; CL: Synthesize

52. 3. Cimetidine is a histamine receptor antagonist that decreases the quantity of gastric secretions. It may be used in hiatal hernia therapy to prevent or treat the esophagitis and heartburn associated with reflux. Cimetidine is not used to prevent reflux, dysphagia, or ulcer development.

CN: Pharmacological and parenteral therapies; CL: Apply

53. 2. Most clients can be treated successfully with a combination of diet restrictions, medications, weight control, and lifestyle modifications. Surgery to correct a hiatal hernia, which commonly produces complications, is performed only when medical therapy fails to control the symptoms.

CN: Reduction of risk potential; CL: Synthesize

Managing Care, Quality, and Safety of Clients with Upper Gastrointestinal Tract Health Problems

54. 1. Immediately after surgery, the client should be placed on the side with the head slightly elevated. This position helps facilitate removal of secretions and decreases the likelihood of aspiration should vomiting occur. An RN  does not need to be present to reposition the client, unless the client's condition warrants the presence of the nurse. Although it is important to elevate the head, there is no need to keep the client's head elevated on two pillows unless that position is comfortable for the client.

 CN: Reduction of risk potential; CL: Synthesize

55. 3,4,2,1. The client with peptic ulcer disease who is experiencing a sudden onset of acute stomach pain should be assessed first by the nurse. The sudden onset of stomach pain could be indicative of a perforated ulcer, which would require immediate medical attention. It is also important for the nurse to thoroughly assess the nature of the client's pain. The client with the fractured jaw is experiencing pain and should be assessed next. The nurse should then assess the client who is NPO for tests to ensure NPO status and comfort. Last, the nurse can assess the client before surgery.

 CN: Management of care; CL: Synthesize

56. 1. A sudden spike in temperature following an endoscopic procedure may indicate perforation of the GI tract. The nurse should promptly conduct a further assessment of the client, looking for further indicators of perforation, such as a sudden onset of acute upper abdominal pain; a rigid, board-like abdomen; and developing signs of shock. Telling the assistant to change thermometers is not an appropriate action and only further delays the appropriate action of assessing the client. The nurse would not administer acetaminophen without further assessment of the client or without a **healthcare provider's (HCP's)**  prescription; a suspected perforation would require that the client be placed on nothing-by-mouth status. Asking the assistant to bathe the client before any assessment by the nurse is inappropriate.

 CN: Management of care; CL: Synthesize

57. 3. Parotitis is inflammation of the parotid gland. Although any of the clients listed could develop parotitis, given the data provided, the one most likely to develop parotitis is the elderly client who is dehydrated with poor oral hygiene. Any client who experiences poor oral hygiene is at risk for developing parotitis. To help prevent parotitis, it is essential for the nurse to ensure the client receives oral hygiene at regular intervals and has an adequate fluid intake.

CN: Reduction of risk potential; CL: Analyze

58. 2. A soft toothbrush should be used to brush the client's teeth after every meal and more often as needed. Mechanical cleaning is necessary to maintain oral health, stimulate gingiva, and remove plaque. Assessing the oral cavity and recording observations are the responsibilities of the nurse, not of the UAP . Swabbing with a safe foam applicator does not provide enough friction to clean the mouth. Mouthwash can be a drying irritant and is not recommended for frequent use.

CN: Basic care and comfort; CL: Synthesize

59. 1. The Cochrane Library provides systematic reviews of healthcare interventions and will provide the best resource for evidence for nursing care. The CINAHL offers key word searches to published articles in nursing and allied health literature, but not reviews. A nursing textbook has information about nursing care, which may include evidence-based practices, but textbooks may not have the most up-to-date information. While the policy and procedure manual may be based on evidence-based practices, the most current practices will be found in evidence-based reviews of literature.

CN: Management of care; CL: Apply

60. 3. Using a checklist assures that all key information is reported; the checklist can then serve as a record to which nurses can refer later. Giving a verbal report leaves room for error in memory; using an audiotape or an electronic health record requires nurses to spend unnecessary time retrieving information.

CN: Safety and infection control; CL: Apply

61. 1,4. Though still responsible for follow-up to make sure oral care is

completed and accurate intake and output is ongoing, these are appropriate tasks to delegate to **UAP** 📖. Evaluating level of consciousness (orientation), pain, and the effect of medications given by the nurse requires nursing judgment and should not be delegated to UAP. While UAP often assist clients with bathing, dressing changes are not delegated to UAP as the wound should be assessed by a nurse while changing the dressing.

CN: Management of care; CL: Synthesize

The Client with Lower Gastrointestinal Tract Health Problems

- The Client with Cancer of the Colon
- The Client with Hemorrhoids
- The Client with Inflammatory Bowel Disease
- The Client with an Intestinal Obstruction
- The Client with an Ileostomy
- The Client Receiving Total Parenteral Nutrition
- The Client with Diverticular Disease
- The Client with Appendicitis
- The Client with an Inguinal Hernia
- Managing Care, Quality, and Safety of Clients with Lower Gastrointestinal Tract Health Problems
- Answers, Rationales, and Test-Taking Strategies

The Client with Cancer of the Colon

1. Which guideline reflects the current American and Canadian Cancer Societies' recommendations for screening for colon cancer in individuals who are **not** at high risk?

- ☐ **1.** Annual digital rectal examination should begin at age 40.
- ☐ **2.** Annual fecal testing for occult blood should begin at age 50.
- ☐ **3.** Individuals should obtain a baseline barium enema at age 40.
- ☐ **4.** Individuals should obtain a baseline colonoscopy at age 45.

2. A client refuses to look at or care for her colostomy. Which statement by the nurse would be **most** appropriate?

- ☐ 1. “It has been 4 days since your surgery, and you will soon be discharged. You have to learn to care for your colostomy before you leave the hospital.”
- ☐ 2. “I think we will need to teach your husband to care for your colostomy if you are not going to be able to do it.”
- ☐ 3. “I understand how you are feeling. It is important for you to feel attractive, and you think having a colostomy changes your attractiveness.”
- ☐ 4. “I can see that you are upset. Would you like to share your concerns with me?”

3. The nurse should teach clients about which potential risk factor for the development of colon cancer?

- ☐ 1. chronic constipation
- ☐ 2. long-term use of laxatives
- ☐ 3. history of smoking
- ☐ 4. history of inflammatory bowel disease

4. A client had a colon resection yesterday. The client’s hemoglobin was 14.1 g/dL yesterday and today it is 7.2 g/dL. The client’s oxygen saturation is 87%. After reviewing the chart (see chart) and notifying the healthcare provider (HCP), the nurse should **first**:

Prescriptions

1000 mL normal saline every 8 hours at 125 gtts/h

Vital signs every 4 hours

Morphine sulfate 10 mg IV every 4 hours as needed for pain

Nothing by mouth

Oxygen 2–4 L/min per mask

- ☐ 1. Take the vital signs every hour.
- ☐ 2. Increase the saline infusion to 150 gtts/h.
- ☐ 3. Administer oxygen at 2 L/min.
- ☐ 4. Determine when last pain medication was administered.

5. A client with colon cancer is having a barium enema. The nurse should instruct the client to take which type of medication after the procedure is completed?

- ☐ 1. laxative
- ☐ 2. anticholinergic
- ☐ 3. antacid
- ☐ 4. demulcent

6. A client has a nasogastric tube inserted at the time of abdominal-perineal resection with permanent colostomy for colon cancer. This tube will most likely be removed when the client demonstrates:

- ☐ 1. absence of nausea and vomiting.
- ☐ 2. passage of mucus from the rectum.

- ☐ 3. passage of flatus and feces from the colostomy.
- ☐ 4. absence of stomach drainage for 24 hours.

7. The client with colon cancer has an abdominal-perineal resection with a colostomy. To promote hygiene following surgery, what should the nurse do?

- ☐ 1. Maintain the client in a semi-Fowler's position.
- ☐ 2. Assist the client with warm sitz baths.
- ☐ 3. Administer 30 mL of milk of magnesia to stimulate peristalsis.
- ☐ 4. Remove the ostomy pouch as needed so the stoma can be assessed.

8. The nurse assesses the client's stoma during the initial postoperative period. What observation should the nurse report to the healthcare provider (HCP) **immediately**?

- ☐ 1. The stoma is slightly edematous.
- ☐ 2. The stoma is dark red to purple.
- ☐ 3. The stoma oozes a small amount of blood.
- ☐ 4. The stoma does not expel stool.

9. While changing the client's colostomy bag and dressing, the nurse determines that the client is ready to participate in self-care when the client:

- ☐ 1. asks if the healthcare provider (HCP) will change the dressing soon.
- ☐ 2. asks about the supplies used during the dressing change.
- ☐ 3. talks about the news on the television.
- ☐ 4. is upset about the way the night nurse changed the dressing.

10. Which skin preparation would be **best** to apply around the client's colostomy?

- ☐ 1. adhesive skin barrier
- ☐ 2. petroleum jelly
- ☐ 3. cornstarch
- ☐ 4. antiseptic cream

11. When planning diet teaching for the client with a colostomy, the nurse should develop a plan that emphasizes which dietary instruction?

- ☐ 1. Foods containing roughage should not be eaten.
- ☐ 2. Liquids are best limited to prevent diarrhea.

- ☐ 3. Clients should experiment to find the diet that is best for them.
- ☐ 4. A high-fiber diet will produce a regular passage of stool.

12. What is an expected outcome for a client during the first 2 weeks who is recovering from an abdominal-perineal resection with a colostomy? The client will:

- ☐ 1. maintain a fluid intake of 3,000 mL/day.
- ☐ 2. eliminate fiber from the diet.
- ☐ 3. limit physical activity to light exercise.
- ☐ 4. accept that sexual activity will be diminished.

13. A client with colon cancer has developed ascites. The nurse should conduct a focused assessment for which signs and symptoms? Select all that apply.

- ☐ 1. respiratory distress
- ☐ 2. bleeding
- ☐ 3. fluid and electrolyte imbalance
- ☐ 4. weight gain
- ☐ 5. infection

14. A client has 4,000 mL removed via paracentesis. When the nurse weighs the client after the procedure, how many kilograms is an expected weight loss? Record your answer in whole numbers. kg.

15. Two days following a colon resection, an elderly client shows new onset of confusion. When contacting the healthcare provider (HCP), the nurse should make which recommendation?

- ☐ 1. "Do you want a CT scan to rule out stroke?"
- ☐ 2. "May we have a prescription for restraining this client?"
- ☐ 3. "Shall I collect and send a urine sample for culture and sensitivity?"
- ☐ 4. "Would you like a stat potassium level done?"

16. The nurse is caring for a 70-year-old male client after a colectomy. The client has received chemotherapy prior to surgery and has hypertension and diabetes mellitus. Which factors put this client at risk for sepsis? Select all that apply.

- ☐ 1. age
- ☐ 2. abdominal surgery
- ☐ 3. gender
- ☐ 4. diabetes mellitus
- ☐ 5. weight

The Client with Hemorrhoids

17. A 36-year-old female client has been diagnosed with hemorrhoids. Which factor in the client's history would **most** likely be a primary cause of her hemorrhoids?

- ☐ 1. her age
- ☐ 2. three vaginal delivery pregnancies
- ☐ 3. her job as a schoolteacher
- ☐ 4. varicosities in her legs

18. The nurse instructs the client who has had a hemorrhoidectomy not to use sitz baths until at least 12 hours postoperatively to avoid inducing which complication?

- ☐ 1. hemorrhage
- ☐ 2. rectal spasm
- ☐ 3. urine retention
- ☐ 4. constipation

19. The nurse teaches the client who has had rectal surgery the proper timing for a cleansing sitz baths. The client has understood the teaching when the client states that it is **most** important to take a sitz bath:

- ☐ 1. first thing each morning.
- ☐ 2. as needed for discomfort.
- ☐ 3. after a bowel movement.
- ☐ 4. at bedtime.

The Client with Inflammatory Bowel Disease

20. A client has been placed on long-term sulfasalazine therapy for treatment of ulcerative colitis. The nurse should encourage the client to eat

which foods to help avoid the nutrient deficiencies that may develop as a result of this medication?

- ☐ 1. citrus fruits
- ☐ 2. green, leafy vegetables
- ☐ 3. eggs
- ☐ 4. milk products

21. A client who has had ulcerative colitis for the past 5 years is admitted to the hospital with an exacerbation of the disease. Which factor is of **greatest** significance in causing an exacerbation of ulcerative colitis?

- ☐ 1. a demanding and stressful job
- ☐ 2. changing to a modified vegetarian diet
- ☐ 3. beginning a weight-training program
- ☐ 4. walking 2 miles (3.2 km) every day

22. A client who is experiencing an exacerbation of ulcerative colitis is receiving IV fluids that are to be infused at 125 mL/h. The IV tubing delivers 15 gtt/mL. How quickly should the nurse infuse the fluids in drops per minute to infuse the fluids at the prescribed rate? Record your answer using a whole number. gtt/min.

23. Which goal for the client's care should take **priority** during the first days of hospitalization for an exacerbation of ulcerative colitis?

- ☐ 1. promoting self-care and independence
- ☐ 2. managing diarrhea
- ☐ 3. maintaining adequate nutrition
- ☐ 4. promoting rest and comfort

24. The client with ulcerative colitis is to be on bed rest with bathroom privileges. When evaluating the effectiveness of this level of activity, the nurse should determine if the client has:

- ☐ 1. conserved energy.
- ☐ 2. reduced intestinal peristalsis.
- ☐ 3. obtained needed rest.
- ☐ 4. minimized stress.

25. A client has had an exacerbation of ulcerative colitis with cramping and diarrhea persisting longer than 1 week. The nurse should assess the client for which complication?

- ☐ 1. heart failure
- ☐ 2. deep vein thrombosis
- ☐ 3. hypokalemia
- ☐ 4. hypocalcemia

26. A client who has ulcerative colitis says to the nurse, “I cannot take this anymore; I am constantly in pain, and I cannot leave my room because I need to stay by the toilet. I do not know how to deal with this.” Based on these comments, the nurse should determine the client is experiencing:

- ☐ 1. extreme fatigue.
- ☐ 2. disturbed thought.
- ☐ 3. a sense of isolation.
- ☐ 4. difficulty coping.

27. A client newly diagnosed with ulcerative colitis who has been placed on steroids asks the nurse why steroids are prescribed. The nurse should tell the client:

- ☐ 1. “Ulcerative colitis can be cured by the use of steroids.”
- ☐ 2. “Steroids are used in severe flare-ups because they can decrease the incidence of bleeding.”
- ☐ 3. “Long-term use of steroids will prolong periods of remission.”
- ☐ 4. “The side effects of steroids outweigh their benefits to clients with ulcerative colitis.”

28. A client who has ulcerative colitis has persistent diarrhea and has lost 12 lb (5.5 kg) since the exacerbation of the disease. Which approach will be **most** effective in helping the client meet nutritional needs?

- ☐ 1. continuous enteral feedings
- ☐ 2. following a high-calorie, high-protein diet
- ☐ 3. total parenteral nutrition (TPN)
- ☐ 4. eating six small meals a day

29. A client with ulcerative colitis is to take sulfasalazine. Which

instructions should the nurse give the client about taking this medication at home? Select all that apply.

- ☐ 1. Drink enough fluids to maintain a urine output of at least 1,200 to 1,500 mL/day.
- ☐ 2. Discontinue therapy if symptoms of acute intolerance develop, and notify the healthcare provider (HCP).
- ☐ 3. Stop taking the medication if the urine turns orange-yellow.
- ☐ 4. Avoid activities that require alertness.
- ☐ 5. If dose is missed, skip and continue with the next dose.

30. The nurse has a prescription to administer sulfasalazine 2 g. The medication is available in 500-mg tablets. How many tablets should the nurse administer? tablets.

31. Which diet would be **most** appropriate for the client with ulcerative colitis?

- ☐ 1. high-calorie, low-protein
- ☐ 2. high-protein, low-residue
- ☐ 3. low-fat, high-fiber.
- ☐ 4. low-sodium, high-carbohydrate

32. A client who has a history of Crohn's disease is admitted to the hospital with fever, diarrhea, cramping, abdominal pain, and weight loss. The nurse should monitor the client for:

- ☐ 1. hyperalbuminemia.
- ☐ 2. thrombocytopenia.
- ☐ 3. hypokalemia.
- ☐ 4. hypercalcemia.

33. A client with Crohn's disease has concentrated urine; decreased urinary output; dry skin with decreased turgor; hypotension; and weak, thready pulses. What should the nurse do **first**?

- ☐ 1. Encourage the client to drink at least 1,000 mL/day.
- ☐ 2. Provide parenteral rehydration therapy as prescribed.
- ☐ 3. Turn and reposition every 2 hours.
- ☐ 4. Monitor vital signs every shift.

34. Which is a **priority** focus of care for a client experiencing an exacerbation of Crohn's disease?

- ☐ 1. encouraging regular ambulation
- ☐ 2. promoting bowel rest
- ☐ 3. maintaining current weight
- ☐ 4. decreasing episodes of rectal bleeding

The Client with an Intestinal Obstruction

35. A nurse is assessing a client who has been admitted with a diagnosis of an obstruction in the small intestine. The nurse should assess the client for which signs and symptoms? Select all that apply.

- ☐ 1. projectile vomiting
- ☐ 2. significant abdominal distention
- ☐ 3. copious diarrhea
- ☐ 4. rapid onset of dehydration
- ☐ 5. increased bowel sounds

36. A client is admitted with a bowel obstruction. The client has nausea, vomiting, and crampy abdominal pain. The healthcare provider (HCP) has written the following prescriptions: for the client to be up ad lib, have narcotics for pain, have a nasogastric tube inserted if needed, and for IV, Ringer's lactate and hyperalimentation fluids. What should the nurse do in order of priority from first to last? All options must be used.

1. Assist with ambulation to promote peristalsis.

2. Insert a nasogastric tube.

3. Administer IV Ringer's lactate.

4. Start an infusion of hyperalimentation fluids.

37. The healthcare provider (HCP) prescribes intestinal decompression with a Cantor tube for a client with an intestinal obstruction. In order to determine effectiveness of intestinal decompression, the nurse should evaluate the client to determine if:

- ☐ 1. intestinal fluid and gas have been removed.
- ☐ 2. the client has had a bowel movement.
- ☐ 3. the client's urinary output is adequate.
- ☐ 4. the client can sit up without pain.

38. After insertion of a nasoenteric tube, the nurse should place the client in which position?

- ☐ 1. supine
- ☐ 2. right side-lying
- ☐ 3. semi-Fowler's
- ☐ 4. upright in a bedside chair

39. What should the nurse tell the client who is preparing for insertion of a nasoduodenal tube? Select all that apply.

- ☐ 1. The nose and throat will be numbed with a viscous anesthetic.
- ☐ 2. The tube will be placed at the bedside.
- ☐ 3. X-rays with the use of a contrast dye will be used to verify placement.
- ☐ 4. The client will be closely monitored for 30 minutes following the procedure.
- ☐ 5. The tube will be taped to the nose.

40. The client with an intestinal obstruction continues to have acute pain even though the nasoenteric tube is patent and draining. The nurse should **first**:

- ☐ 1. reassure the client that the nasoenteric tube is functioning.

- ☐ 2. assess the client for signs of peritonitis.
- ☐ 3. administer an opioid as prescribed.
- ☐ 4. reposition the client on the left side.

41. Before abdominal surgery for an intestinal obstruction, the nurse monitors the client's urine output and finds that the total output for the past 2 hours was 35 mL. The nurse then assesses the client's total intake and output over the last 24 hours and notes 2,000 mL of IV fluid for intake, 500 mL of drainage from the nasogastric tube, and 700 mL of urine for a total output of 1,200 mL. These findings indicate:

- ☐ 1. decreased renal function.
- ☐ 2. the nasogastric tube is not draining well.
- ☐ 3. extension of the obstruction.
- ☐ 4. inadequate fluid replacement.

The Client with an Ileostomy

42. The nurse is teaching the client how to care for an ileostomy. The client asks the nurse how long to wear the pouch before changing it. The nurse should tell the client:

- ☐ 1. "The pouch is changed only when it leaks."
- ☐ 2. "You can wear the pouch for about 4 to 7 days."
- ☐ 3. "You should change the pouch every evening before bedtime."
- ☐ 4. "It depends on your activity level and your diet."

43. A client is scheduled for an ileostomy. Which would be **most** helpful in preparing the client psychologically for the surgery?

- ☐ 1. Include family members in preoperative teaching sessions.
- ☐ 2. Encourage the client to ask questions about managing an ileostomy.
- ☐ 3. Provide a brief, thorough explanation of all preoperative and postoperative procedures.
- ☐ 4. Invite a member of the ostomy association to visit the client.

44. Two weeks before a client was scheduled for an ileostomy, and the nurse should instruct the client to:

- ☐ 1. stop taking drugs that will interfere with clotting (aspirin, ibuprofen).

- ☐ 2. follow a low-residue diet.
- ☐ 3. abstain from having sex.
- ☐ 4. report having a temperature above 99°F (37.2°C).

45. Immediately after having surgery to create an ileostomy, which goal has the **highest priority**?

- ☐ 1. providing relief from constipation
- ☐ 2. assisting the client with self-care activities
- ☐ 3. maintaining fluid and electrolyte balance
- ☐ 4. minimizing odor formation

46. The client asks the nurse, “Is it really possible to lead a normal life with an ileostomy?” Which action by the nurse would be the **most** effective to address this question?

- ☐ 1. Have the client talk with a member of the clergy about these concerns.
- ☐ 2. Tell the client to worry about those concerns after surgery.
- ☐ 3. Arrange for a person with an ostomy to visit the client preoperatively.
- ☐ 4. Notify the surgeon of the client’s question.

47. Three weeks after the client has had an ileostomy, the nurse is following up with instruction about using a skin barrier around the stoma at all times. The client has been applying the skin barrier correctly when:

- ☐ 1. there is no odor from the stoma.
- ☐ 2. the client is adequately hydrated.
- ☐ 3. there is no skin irritation around the stoma.
- ☐ 4. the client only changes the ostomy pouch once a day.

48. What observation should the nurse instruct the client with an ileostomy to report **immediately**?

- ☐ 1. passage of liquid stool from the stoma
- ☐ 2. occasional presence of undigested food in the effluent
- ☐ 3. absence of drainage from the ileostomy for 6 or more hours
- ☐ 4. temperature of 99.8°F (37.7°C)

49. The nurse finds the client who has had an ileostomy crying. The client explains to the nurse, “I am upset because I know I will not be able to have

children now that I have an ileostomy.” Which response by the nurse is **best**?

- ☐ 1. “Many women with ileostomies decide to adopt. Perhaps you could consider that option?”
- ☐ 2. “Having an ileostomy does not necessarily mean that you cannot bear children. Let us talk about your concerns.”
- ☐ 3. “I can understand your reasons for being upset. Having children must be important to you.”
- ☐ 4. “I am sure you will adjust to this situation with time. Try not to be too upset.”

50. Which statement about ileostomy care indicates that the client understands the discharge instruction?

- ☐ 1. “I should be able to resume weight lifting in 2 weeks.”
- ☐ 2. “I can return to work in 2 weeks.”
- ☐ 3. “I need to drink at least 3,000 mL a day of fluid.”
- ☐ 4. “I will need to avoid getting my stoma wet while bathing.”

51. A client with a well-managed ileostomy has sudden onset of abdominal cramps, vomiting, and watery discharge from the ileostomy. The nurse should:

- ☐ 1. tell the client to take an antiemetic.
- ☐ 2. encourage the client to increase fluid intake to 3 L/day to replace fluid lost through vomiting.
- ☐ 3. instruct the client to take 30 mL of milk of magnesia to stimulate a bowel movement.
- ☐ 4. notify the healthcare provider (HCP).

The Client Receiving Total Parenteral Nutrition

52. The nurse is changing the subclavian dressing of a client who is receiving total parenteral nutrition. When assessing the catheter insertion site, the nurse notes the presence of yellow drainage from around the sutures that are anchoring the catheter. What should the nurse do **first**?

- ☐ 1. Clean the insertion site and redress the area.
- ☐ 2. Document assessment findings in the client’s chart.

- ☐ 3. Request a prescription to obtain a culture of the drainage.
- ☐ 4. Check the client's temperature.

53. Total parenteral nutrition (TPN) is prescribed for a client who has recently had a small and large bowel resection and who is currently not taking anything by mouth. The nurse should:

- ☐ 1. administer TPN through a nasogastric or gastrostomy tube.
- ☐ 2. handle TPN using strict aseptic technique.
- ☐ 3. auscultate for the presence of bowel sounds prior to administering TPN.
- ☐ 4. designate a peripheral intravenous (IV) site for TPN administration.

54. Using a sliding scale schedule, the nurse is preparing to administer an evening dose of regular insulin to a client who is receiving total parenteral nutrition (TPN). The nurse should base the dosage on the:

- ☐ 1. glucometer reading of the client's glucose level obtained immediately before administering the insulin.
- ☐ 2. fasting blood glucose level obtained earlier in the day.
- ☐ 3. amount of TPN fluid the client has received since the last dose of insulin.
- ☐ 4. client's dietary intake for the evening meal and snack.

55. A client with inflammatory bowel disease is receiving total parenteral nutrition (TPN). The basic component of the client's TPN solution is **most** likely to be:

- ☐ 1. an isotonic dextrose solution.
- ☐ 2. a hypertonic dextrose solution.
- ☐ 3. a hypotonic dextrose solution.
- ☐ 4. a colloidal dextrose solution.

56. A nurse is assisting with the removal of a central venous access device (CVAD). The nurse should:

- ☐ 1. turn the client to the left side.
- ☐ 2. have the client exhale slowly and evenly.
- ☐ 3. elevate the head of the bed.
- ☐ 4. instruct the client to take a deep breath and hold it.

57. TPN is prescribed for a client with Crohn's disease. The TPN solution is having an intended outcome when:

- ☐ 1. the client's nutritional needs are met.
- ☐ 2. the client does not have metabolic acidosis.
- ☐ 3. the client is hydrated.
- ☐ 4. the client is in a negative nitrogen balance.

58. A client is receiving total parenteral nutrition (TPN) solution. The nurse should assess a client's ability to metabolize the TPN solution adequately by monitoring the client for which sign? Select all that apply.

- ☐ 1. tachycardia
- ☐ 2. hypertension
- ☐ 3. elevated blood urea nitrogen concentration
- ☐ 4. hyperglycemia

59. To prevent complications associated with TPN administered through a central line, the nurse should:

- ☐ 1. use strict aseptic technique for all dressing changes.
- ☐ 2. secure all connections of the system.
- ☐ 3. encourage bed rest.
- ☐ 4. cover the insertion site with a moisture-proof dressing.

60. The nurse administers fat emulsion solution during TPN as prescribed based on the understanding that this type of solution:

- ☐ 1. provides essential fatty acids.
- ☐ 2. provides extra carbohydrates.
- ☐ 3. promotes effective metabolism of glucose.
- ☐ 4. maintains a normal body weight.

61. Which finding indicates a complication after the first few days of TPN therapy?

- ☐ 1. glycosuria
- ☐ 2. a 1- to 2-lb (0.45- to 0.9-kg) weight gain
- ☐ 3. decreased appetite
- ☐ 4. elevated temperature

62. Which adverse effects occur when there is too rapid an infusion of TPN solution?

- ☐ 1. negative nitrogen balance
- ☐ 2. circulatory overload
- ☐ 3. hypoglycemia
- ☐ 4. hypokalemia

The Client with Diverticular Disease

63. Following the acute stage of diverticulosis, which foods should the nurse encourage a client to incorporate into the diet? Select all that apply.

- ☐ 1. bran cereal
- ☐ 2. broccoli
- ☐ 3. tomato juice
- ☐ 4. navy beans
- ☐ 5. cheese

64. When a client has an acute attack of diverticulitis, the nurse should first:

- ☐ 1. prepare the client for a colonoscopy.
- ☐ 2. encourage the client to eat a high-fiber diet.
- ☐ 3. assess the client for signs of peritonitis.
- ☐ 4. encourage the client to drink a glass of water every 2 hours.

65. A barium enema is not prescribed as a diagnostic test for a client with diverticulitis because a barium enema:

- ☐ 1. can perforate an intestinal abscess.
- ☐ 2. would greatly increase the client's pain.
- ☐ 3. is of minimal diagnostic value in diverticulitis.
- ☐ 4. is too lengthy a procedure for the client to tolerate.

66. The nurse should teach the client with diverticulitis to integrate which measure into a daily routine at home?

- ☐ 1. using enemas to relieve constipation
- ☐ 2. decreasing fluid intake to increase the formed consistency of the stool

- ☐ 3. eating a high-fiber diet when symptomatic with diverticulitis
- ☐ 4. refraining from straining and lifting activities

67. After instructing a client with diverticulosis about appropriate self-care activities, which comment by the client indicates effective teaching? Select all that apply.

- ☐ 1. "With careful attention to my diet, my diverticulosis can be cured."
- ☐ 2. "Using a cathartic laxative weekly is okay to control bowel movements."
- ☐ 3. "I should follow a diet that is high in fiber."
- ☐ 4. "It is important for me to drink at least 2,000 mL of fluid every day."
- ☐ 5. "I should exercise regularly."

68. A client with diverticular disease is receiving psyllium hydrophilic mucilloid. The drug has been effective when the client:

- ☐ 1. passes stool without cramping.
- ☐ 2. does not have diarrhea.
- ☐ 3. has firm, well-formed stool.
- ☐ 4. does not expel gas.

69. A client with diverticulitis has developed peritonitis following diverticular rupture. When assessing the client, what should the nurse do? Select all that apply.

- ☐ 1. Percuss the abdomen to note tympany.
- ☐ 2. Percuss the liver to note lack of dullness.
- ☐ 3. Monitor the vital signs for fever.
- ☐ 4. Assess presence of excessive thirst.
- ☐ 5. Auscultate bowel sounds to note frequency.

The Client with Appendicitis

70. A nurse is providing wound care to a client 1 day following an appendectomy. A drain was inserted into the incisional site during surgery. When providing wound care, the nurse should:

- ☐ 1. remove the dressing and leave the incision open to air.

- ☐ 2. remove the drain if wound drainage is minimal.
- ☐ 3. gently irrigate the drain to remove exudate.
- ☐ 4. clean the area around the drain moving away from the drain.

71. An adult with appendicitis has severe abdominal pain. Which action will be the **most** effective to assist the client to manage pain prior to surgery?

- ☐ 1. Place the client in semi-Fowler's position with the knees to the chest.
- ☐ 2. Apply moist heat to the abdomen.
- ☐ 3. Teach client to massage the painful area.
- ☐ 4. Provide distraction with music.

72. Postoperative nursing care for a client after an appendectomy should include:

- ☐ 1. administering sitz baths four times a day.
- ☐ 2. noting the first bowel movement after surgery.
- ☐ 3. limiting the client's activity to bathroom privileges.
- ☐ 4. measuring abdominal girth every 2 hours.

73. A client who had an appendectomy for a perforated appendix returns from surgery with a drain inserted in the incisional site. The purpose of the drain is to:

- ☐ 1. provide access for wound irrigation.
- ☐ 2. promote drainage of wound exudates.
- ☐ 3. minimize development of scar tissue.
- ☐ 4. decrease postoperative discomfort.

The Client with an Inguinal Hernia

74. A client who has a history of an inguinal hernia is admitted to the hospital with sudden, severe abdominal pain, vomiting, and abdominal distention. The nurse should assess the client further for which complication?

- ☐ 1. peritonitis
- ☐ 2. incarcerated hernia
- ☐ 3. strangulated hernia
- ☐ 4. intestinal perforation

75. The nurse is providing discharge instructions for a client who had an inguinal herniorrhaphy. The nurse should teach the client to:

- ☐ 1. cough and deep breathe every 2 hours.
- ☐ 2. apply warm, moist heat to the groin.
- ☐ 3. sneeze with mouth closed.
- ☐ 4. avoid lifting items weighing more than 5 lb.

76. After an inguinal herniorrhaphy, the nurse should assess the male client carefully for which complication?

- ☐ 1. hypostatic pneumonia
- ☐ 2. deep vein thrombosis
- ☐ 3. paralytic ileus
- ☐ 4. urine retention

Managing Care, Quality, and Safety for Clients with Lower Gastrointestinal Tract Health Problems

77. A client has anemia resulting from bleeding from ulcerative colitis and is to receive two units of packed red blood cells (PRBCs). The client is receiving an infusion of total parenteral nutrition (TPN). In preparing to administer the PRBCs, what should the nurse do to ensure client comfort and safety?

- ☐ 1. Discontinue the TPN infusion.
- ☐ 2. Start an IV infusion of normal saline.
- ☐ 3. Administer PRBCs in the same IV as the TPN.
- ☐ 4. Wait until the TPN infusion is completed, and use the same IV line to infuse the PRBCs.

78. The nurse is assigning clients for the evening shift. Which clients are appropriate for the nurse to assign to a licensed practical/vocational nurse (LPN/VN) to provide client care? Select all that apply.

- ☐ 1. a client with Crohn's disease who is receiving total parenteral nutrition (TPN)
- ☐ 2. a client who had inguinal hernia repair surgery 3 hours ago; vital signs are stable

- ☐ 3. a client with an intestinal obstruction who needs a Cantor tube inserted
- ☐ 4. a client with diverticulitis who needs teaching about take home medications
- ☐ 5. a client who is experiencing an exacerbation of ulcerative colitis

79. When planning care for a client with ulcerative colitis who is experiencing an exacerbation of symptoms, which client care activities can the nurse appropriately delegate to an unlicensed assistive personnel (UAP)? Select all that apply.

- ☐ 1. assessing the client's bowel sounds
- ☐ 2. providing skin care following bowel movements
- ☐ 3. evaluating the client's response to antidiarrheal medications
- ☐ 4. maintaining intake and output records
- ☐ 5. obtaining the client's weight

80. The nurse is caring for a client 1 day after having a colectomy. The client is lethargic and difficult to arouse; the temperature is 101.5°F (38.6°C), blood pressure is 92/36 mm Hg (MAP 55), and heart rate is 114 bpm with SpO2 of 88% on oxygen at 2 L/min/nasal cannula (previously 94%). A saline lock has been established and is patent. Which prescription should the nurse implement **first**?

- ☐ 1. Obtain stat portable chest x-ray.
- ☐ 2. Administer vancomycin intravenously.
- ☐ 3. Draw blood cultures.
- ☐ 4. Insert an indwelling urinary catheter.

81. The nurse is taking care of a client with *Clostridium difficile* (*C. difficile*). To prevent the spread of infection, what should the nurse do? Select all that apply.

- ☐ 1. Wear a particulate respirator.
- ☐ 2. Wear sterile gloves when providing care.
- ☐ 3. Cleanse hands with alcohol-based hand sanitizer.
- ☐ 4. Wash hands with soap and water.
- ☐ 5. Wear a protective gown when in the client's room.

82. The nurse discovers that a client's TPN solution was running at an

incorrect rate and is now 2 hours behind schedule. Which action is **most** appropriate for the nurse to take to correct the problem?

- ☐ 1. Readjust the solution to infuse the desired amount.
- ☐ 2. Continue the infusion at the current rate, but run the next bottle at an increased rate.
- ☐ 3. Double the infusion rate for 2 hours.
- ☐ 4. Notify the healthcare provider (HCP).

83. The nurse is to administer ampicillin 500 mg orally to a client with a ruptured appendix. The nurse checks the capsule in the client's medication box, which is located inside of the client's room. The dosage of the medication is not labeled, but the nurse recognizes the color and shape of the capsule. The nurse should **next**:

- ☐ 1. administer the medication to maintain blood levels of the drug.
- ☐ 2. ask another registered nurse (RN) to verify that the capsule is ampicillin.
- ☐ 3. contact the pharmacy to bring a properly labeled medication.
- ☐ 4. notify the unit manager to report the problem.

84. On the 2nd day following an abdominal-perineal resection, the nurse notes that the wound edges are not approximated and one-half of the incision has torn apart. What should the nurse do **first**?

- ☐ 1. Flush the wound with sterile water.
- ☐ 2. Apply an abdominal binder.
- ☐ 3. Cover the wound with a sterile dressing moistened with normal saline.
- ☐ 4. Apply strips of tape.

85. A client has received numerous different antibiotics and now is experiencing diarrhea. The healthcare provider (HCP) has prescribed a transmission-based precaution. The nurse should institute:

- ☐ 1. airborne precautions.
- ☐ 2. contact precautions.
- ☐ 3. droplet precautions.
- ☐ 4. needlestick precautions.

86. The healthcare provider (HCP) has prescribed ciprofloxacin for a

client who takes warfarin. What should the nurse instruct the client to do? Select all that apply.

- ☐ 1. Split the tablets and stir them in food.
- ☐ 2. Avoid exposure to sunlight.
- ☐ 3. Eliminate caffeine from the diet.
- ☐ 4. Report unusual bleeding.
- ☐ 5. Increase fluid intake to 3,000 mL/day.

Answers, Rationales, and Test-Taking Strategies

The answers and rationales for each question follow below, along with keys () to the client need (CN) and cognitive level (CL) for each question. In addition, you will also see a glossary icon () highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 12–23 and pages 35–36 in Part 1 of this book.

The Client with Cancer of the Colon

1. 2. Annual fecal testing for occult blood should begin at age 50. Annual digital rectal examinations are recommended in men beginning at age 50 to screen for prostate cancer. Baseline barium enemas or colonoscopies are recommended at age 50. Baseline barium enemas and colonoscopies are not performed on individuals in their 40s unless they experience signs or symptoms that indicate the need for such diagnostic testing or are considered to be at high risk.

CN: Health promotion and maintenance; CL: Apply

2. 4. It is important for the nurse to recognize that individuals go through a grieving process when adjusting to a colostomy. The nurse should be accepting and provide the client with opportunities to share her concerns and feelings when she is ready. Lecturing the client about the need to learn how

to care for the colostomy is not productive nor is attempting to shame her into caring for the colostomy by implying her husband will have to provide the care if she does not. It is not possible for the nurse to understand what the client is feeling.

 CN: Psychosocial adaptation; CL: Synthesize

3. 4. A history of inflammatory bowel disease is a risk factor for colon cancer. Other risk factors include age (older than 40 years), history of familial polyposis, colorectal polyps, and high-fat or low-fiber diet.

 CN: Reduction of risk potential; CL: Analyze

4. 3. This client has decreased oxygen saturation and also decreased hemoglobin, which puts the client at great risk for cardiac ischemia. The nurse should start the oxygen as prescribed. The nurse can take the vital signs more frequently once the oxygen flow has been started. It is not appropriate to increase the rate of the intravenous infusion, and it would be necessary to request a prescription to do so. After starting the oxygen, the nurse can ask the client about the current pain level.

 CN: Physiological Adaptation; CL: Synthesize

5. 1. After a barium enema, a laxative is ordinarily prescribed. This is done to promote elimination of the barium. Retained barium predisposes the client to constipation and fecal impaction. Anticholinergic drugs decrease gastrointestinal motility. Antacids decrease gastric acid secretion. Demulcents soothe mucous membranes of the gastrointestinal tract and are used to treat diarrhea.

 CN: Reduction of risk potential; CL: Synthesize

6. 3. A sign indicating that a client's colostomy is open and ready to function is passage of feces and flatus. When this occurs, gastric suction is ordinarily discontinued, and the client is allowed to start taking fluids and food orally. Absence of bowel sounds would indicate that the tube should remain in place because peristalsis has not yet returned.

 CN: Physiological adaptation; CL: Analyze

7. 2. Appropriate nursing interventions after an abdominal-perineal

resection with a colostomy include assisting the client with warm sitz baths three to four times a day to clean the perineal incision. The client will be more comfortable assuming a side-lying position because of the perineal incision. It would be inappropriate to administer milk of magnesia to stimulate colostomy activity. Stool passage will begin as peristalsis returns. It is not necessary or desirable to change the ostomy pouch daily to assess the stoma. The ostomy pouch should be transparent to allow easy observation of the stoma and drainage.

CN: Physiological adaptation; CL: Synthesize

8. 2. A dark red to purple stoma indicates inadequate blood supply. Mild edema and slight oozing of blood are normal in the early postoperative period. The colostomy would typically not begin functioning until 2 to 4 days after surgery.

CN: Physiological adaptation; CL: Analyze

9. 2. A client who displays interest in the procedure and asks about supplies used for dressings may be ready to participate in self-care. Inquiring about when the **HCP** will change the dressing does not indicate the client's readiness to change the dressing. Discussing news events and discussing a dressing change are behaviors that avoid the subject of the colostomy.

CN: Basic care and comfort; CL: Analyze

10. 1. An adhesive skin barrier is effective for protecting the skin around a colostomy to keep the skin healthy and prevent skin irritation from stoma drainage. Petroleum jelly, cornstarch, and antiseptic creams do not protect the skin adequately and may prevent an adequate seal between the skin and the colostomy bag.

CN: Basic care and comfort; CL: Apply

11. 3. It is best to adjust the diet of a client with a colostomy in a manner that suits the client rather than trying special diets. Severe restriction of roughage is not recommended. The client is encouraged to drink 2 to 3 L of fluid per day. A high-fiber diet may produce loose stools.

CN: Basic care and comfort; CL: Create

12. 1. An expected outcome is that the client will maintain a fluid intake of 3,000 mL/day unless contraindicated. There is no need to eliminate fiber from the diet; the client can eat whatever foods are desired, avoiding those that are bothersome. Physical activity does not need to be limited to light exercise. The client can resume normal activities as tolerated, usually within 6 to 8 weeks. The client's sexual activity may be affected, but it does not need to be diminished.

CN: Physiological adaptation; CL: Evaluate

13. 1,3. Ascites limits the movement of the diaphragm leading to respiratory distress. Fluid shift from the intravascular space precipitates fluid and electrolyte imbalances. Weight gain is not a direct consequence of ascites, but weight loss may result in decreased albumin levels. Decreased albumin in the intravascular space results in decreased oncotic pressure, precipitating movement of fluid out of space. A client with ascites is not at increased risk for infection unless a peritoneal tap is done to remove fluid. The risk of bleeding is a result of alterations in liver enzymes affecting coagulation.

CN: Physiological adaptation; CL: Analyze

14. 4 kg. A liter of water weighs 1 kg. Therefore, the client should have a weight of 4 kilograms less than preprocedure weight.

CN: Physiological adaptation; CL: Apply

15. 3. Sending a urine sample for culture and sensitivity is most warranted. An older adult often has confusion when experiencing a bladder infection. While stroke is always a concern, particularly in the older adult, the presenting information most supports a bladder infection and perhaps early-onset urosepsis. Restraining the client may be needed at some point in time, but finding the cause of the client's new onset of confusion has greatest priority. Potassium is usually related to cardiac rhythm irritability rather than confusion.

CN: Physiological adaptation; CL: Analysis

16. 1,2,4. Known risk factors for sepsis include age (<1 year and >65 years old), chronic illness, and invasive procedures. Immunosuppression and

malnourishment are also risk factors. There is no correlation between gender or age and risk for sepsis. Nurses must be aware of risk factors and monitor clients at risk closely for any signs of sepsis.

CN: Reduction of risk potential; CL: Apply

The Client with Hemorrhoids

17. 2. Hemorrhoids are associated with prolonged sitting or standing, portal hypertension, chronic constipation, and prolonged increased intra-abdominal pressure, as associated with pregnancy and the strain of vaginal childbirth. Her job as a schoolteacher does not require prolonged sitting or standing. Age and leg varicosities are not related to the development of hemorrhoids.

CN: Reduction of risk potential; CL: Analyze

18. 1. Applying heat during the immediate postoperative period may cause hemorrhage at the surgical site. Moist heat may relieve rectal spasms after bowel movements. Urine retention caused by reflex spasm may also be relieved by moist heat. Increasing fiber and fluid in the diet can help prevent constipation.

CN: Physiological adaptation; CL: Apply

19. 3. Adequate cleaning of the anal area is difficult but essential. After rectal surgery, sitz baths assist in this process, so the client should take a sitz bath after a bowel movement. Other times are dictated by client comfort.

CN: Reduction of risk potential; CL: Evaluate

The Client with Inflammatory Bowel Disease

20. 2. In long-term sulfasalazine therapy, the client may develop folic acid deficiency. The client can take folic acid supplements, but the nurse should also encourage the client to increase the intake of folic acid in the client's diet. Green, leafy vegetables are a good source of folic acid. Citrus fruits, eggs, and milk products are not good sources of folic acid.

CN: Pharmacological and parenteral therapies; CL: Apply

21. 1. Stressful and emotional events have been clearly linked to exacerbations of ulcerative colitis, although their role in the etiology of the disease has been disproved. A modified vegetarian diet or an exercise program is an unlikely cause of the exacerbation.

 CN: Physiological adaptation; CL: Apply

22. 31 gtt/min. To administer IV fluids at 125 mL/h using tubing that has a drip factor of 15 gtt/mL, the nurse should use the formula:

$$125 \text{ mL}/60 \text{ min} \times 15 \text{ gtt}/1 \text{ mL} = 31 \text{ gtt}/\text{min}$$

 CN: Pharmacological and parenteral therapies; CL: Apply

23. 2. Diarrhea is the primary symptom in an exacerbation of ulcerative colitis, and decreasing the frequency of stools is the first goal of treatment. The other goals are ongoing and will be best achieved by halting the exacerbation. The client may receive antidiarrheal agents, antispasmodic agents, bulk hydrophilic agents, or anti-inflammatory drugs.

 CN: Physiological adaptation; CL: Synthesize

24. 2. Although modified bed rest does help conserve energy and promotes comfort, its primary purpose in this case is to help reduce the hypermotility of the colon. Remaining on bed rest does not by itself reduce stress, and if the client is having stress, the nurse can plan with the client to use strategies that will help the client manage the stress.

 CN: Physiological adaptation; CL: Evaluate

25. 3. Excessive diarrhea causes significant depletion of the body's stores of sodium and potassium as well as fluid. The client should be closely monitored for hypokalemia and hyponatremia. Ulcerative colitis does not place the client at risk for heart failure, deep vein thrombosis, or hypocalcemia.

 CN: Reduction of risk potential; CL: Analyze

26. 4. It is not uncommon for clients with ulcerative colitis to become apprehensive and have difficulty coping with the frequency of stools and the presence of abdominal cramping. During these acute exacerbations, clients

need emotional support and encouragement to verbalize their feelings about their chronic health concerns and assistance in developing effective coping methods. The client has not expressed feelings of fatigue or isolation or demonstrated disturbed thought processes.

CN: Psychosocial adaptation; CL: Analyze

27. 2. Steroids are effective in management of the acute symptoms of ulcerative colitis. Steroids do not cure ulcerative colitis, which is a chronic disease. Long-term use is not effective in prolonging the remission and is not advocated. Clients should be assessed carefully for side effects related to steroid therapy, but the benefits of short-term steroid therapy usually outweigh the potential adverse effects.

CN: Pharmacological and parenteral therapies; CL: Apply

28. 3. Food will be withheld from the client with severe symptoms of ulcerative colitis to rest the bowel. To maintain the client's nutritional status, the client will be started on TPN. Enteral feedings or dividing the diet into six small meals does not allow the bowel to rest. A high-calorie, high-protein diet will worsen the client's symptoms.

CN: Physiological adaptation; CL: Apply

29. 1,2,4. Sulfasalazine may cause dizziness, and the nurse should caution the client to avoid driving or other activities that require alertness until response to medication is known. If symptoms of acute intolerance (cramping, acute abdominal pain, bloody diarrhea, fever, headache, rash) occur, the client should discontinue therapy and notify the **HCP**  immediately. Fluid intake should be sufficient to maintain a urine output of at least 1,200 to 1,500 mL daily to prevent crystalluria and stone formation. The nurse can also inform the client that this medication may cause orange-yellow discoloration of urine and skin, which is not significant and does not require the client to stop taking the medication. The nurse should instruct the client to take missed doses as soon as remembered unless it is almost time for the next dose.

CN: Pharmacological and parenteral therapies; CL: Synthesize

30. 4 tablets. To administer 2 g sulfasalazine, the nurse will need to

administer four tablets. The following formula is used to calculate the correct dosage:

The first step is to convert grams into milligrams:

$$1 \text{ g}/1,000 \text{ mg} = 2 \text{ g}/X \text{ mg}$$

$$X = 2,000 \text{ mg}$$

$$\text{Then, } 2,000 \text{ mg}/X \text{ tablets} = 500 \text{ mg}/1 \text{ tablet}$$

$$X = 4 \text{ tablets}$$

CN: Pharmacological and parenteral therapies; CL: Apply

31. 2. Clients with ulcerative colitis should follow a well-balanced high-protein, high-calorie, low-residue diet, avoiding such high-residue foods as whole-wheat grains, nuts, and raw fruits and vegetables. Clients with ulcerative colitis need more protein for tissue healing and should avoid excess roughage. There is no need for clients with ulcerative colitis to follow low-sodium diets.

CN: Basic care and comfort; CL: Apply

32. 3. Hypokalemia is the most expected laboratory finding owing to the diarrhea. Hypoalbuminemia can also occur in Crohn's disease; however, the client's potassium level is of greater importance at this time because a low potassium level can cause cardiac arrest. Anemia is an expected development, but thrombocytopenia is not. Calcium levels are not affected.

CN: Physiological adaptation; CL: Analyze

33. 2. Initially, the extracellular fluid (ECF) volume with isotonic IV fluids should be administered until adequate circulating blood volume and renal perfusion are achieved. Vital signs should be monitored as parenteral and oral rehydration are achieved. Oral fluid intake should be >1,000 mL/day. Turning and repositioning the client at regular intervals aid in the prevention of skin breakdown, but it is first necessary to rehydrate this client.

CN: Physiological adaptation; CL: Synthesize

34. 2. A priority goal of care during an acute exacerbation of Crohn's disease is to promote bowel rest. This is accomplished through decreasing activity, encouraging rest, and initially placing client on nothing-by-mouth

status while maintaining nutritional needs parenterally. Regular ambulation is important, but the priority is bowel rest. The client will probably lose some weight during the acute phase of the illness. Diarrhea is nonbloody in Crohn's disease, and episodes of rectal bleeding are not expected.

CN: Physiological adaptation; CL: Synthesize

The Client with an Intestinal Obstruction

35. 1,4,5. Signs and symptoms of intestinal obstructions in the small intestine may include projectile vomiting and rapidly developing dehydration and electrolyte imbalances. The client will also have increased bowel sounds, usually high pitched and tinkling. The client would not normally have diarrhea and would have minimal abdominal distention. Pain is intermittent, being relieved by vomiting. Intestinal obstructions in the large intestine usually evolve slowly and produce persistent pain, and vomiting is less common. Clients with a large intestine obstruction may develop obstipation and significant abdominal distention.

CN: Physiological adaptation; CL: Analyze

36. 1,3,2,4. The nurse should first help the client ambulate to try to induce peristalsis; this may be effective and require the least amount of invasive procedures. Next, the nurse should initiate IV fluid therapy to correct fluid and electrolyte imbalances (sodium and potassium) with Ringer's lactate to correct interstitial fluid deficit. Nasogastric (NG) decompression of the GI tract to reduce gastric secretions and nasointestinal tubes may also be used as necessary. Lastly, hyperalimentation can be used to correct protein deficiency from chronic obstruction, paralytic ileus, or infection.

CN: Physiological adaptation; CL: Synthesize

37. 1. Intestinal decompression is accomplished with a Cantor, Harris, or Miller-Abbott tube. These 6- to 10-foot (180- to 300-cm) tubes are passed into the small intestine to the obstruction. They remove accumulated fluid and gas, relieving the pressure. The client will not have an adequate bowel movement until the obstruction is removed. The pressure from the distended intestine should not obstruct urinary output. While the client may be able to more easily sit up, and the pain caused by the intestinal pressure will be less,

these are not the primary indicators for successful intestinal decompression.

CN: Physiological adaptation; CL: Evaluate

38. 2. The client is placed in a right side-lying position to facilitate movement of the mercury-weighted tube through the pyloric sphincter. After the tube is in the intestine, the client is turned from side to side or encouraged to ambulate to facilitate tube movement through the intestinal loops. Placing the client in the supine or semi-Fowler's position or having the client sitting out of bed in a chair will not facilitate tube progression.

CN: Reduction of risk potential; CL: Apply

39. 1,3,4,5. A nasoduodenal tube is used primarily for feeding. The tube is inserted in endoscopy or radiology. Prior to insertion of the tube, the client's nose and throat will be numbed with a viscous anesthetic such as lidocaine. The tube placement is verified by contrast x-rays, and the client is observed for 30 minutes after the insertion to be sure the client does not have an allergic reaction, puncture to the lung, or bleeding. The tube is taped to the nose.

CN: Reduction of risk potential; CL: Apply

40. 2. The client's pain may be indicative of peritonitis, and the nurse should assess for signs and symptoms, such as a rigid abdomen, elevated temperature, and increasing pain. Reassuring the client is important, but accurate assessment of the client is essential. The full assessment should occur before pain relief measures are employed. Repositioning the client to the left side will not resolve the pain.

CN: Reduction of risk potential; CL: Synthesize

41. 4. Considering that there is usually 1 L of insensible fluid loss, this client's output exceeds his intake (intake, 2,000 mL; output, 2,200 mL), indicating deficient fluid volume. The kidneys are concentrating urine in response to low circulating volume, as evidenced by a urine output of <30 mL/h. This indicates that increased fluid replacement is needed. Decreasing urine output can be a sign of decreased renal function, but the data provided suggest that the client is dehydrated. Pain does not affect urine output. There are no data to suggest that the obstruction has worsened.

 CN: Reduction of risk potential; CL: Analyze

The Client with an Ileostomy

42. 2. Unless the pouch leaks, the client can wear the ileostomy pouch for about 4 to 7 days. If leakage occurs, it is important to promptly change the pouch to avoid skin irritation. It is not necessary to change the pouch daily or in the evening. Diet and activity typically do not affect the schedule for changing the pouch.

 CN: Basic care and comfort; CL: Synthesize

43. 3. Providing explanations of preoperative and postoperative procedures helps the client prepare and understand what to expect. It also provides an opportunity for the client to share concerns. Including family members in the teaching sessions is beneficial but does not focus on the client's psychological preparation. Encouraging the client to ask questions about managing the ileostomy may be rushing the client psychologically into accepting the change in body image and function. The client may need time to first handle the stress of surgery and then observe the care of the ileostomy by others before it is appropriate to begin discussing self-management. The nurse should gently explore whether the client is ready to ask questions about management throughout the hospitalization. The client should have the opportunity to express concerns and to agree to an ostomy association visitor before an invitation is extended.

 CN: Psychosocial adaptation; CL: Synthesize

44. 1. The nurse should instruct the client to stop taking drugs that would interfere with clotting, such as aspirin or ibuprofen. The client should follow a high-fiber diet with increased fluids during the 2-week preoperative period. It is not necessary to abstain from sex. The client does not need to report having a temperature above 99°F (37.2°C) to the **healthcare provider (HCP)**  as this is within normal limits; however, if the temperature is higher, this could indicate an infection, and the client should notify the HCP.

 CN: Pharmacological and parenteral therapies; CL: Apply

45. 3. A high-priority outcome after ileostomy surgery is the maintenance

of fluid and electrolyte balance. The client will experience continuous liquid to semiliquid stools. The client should be engaged in self-care activities, and minimizing odor formation is important; however, these goals do not take priority over maintaining fluid and electrolyte balance.

CN: Physiological adaptation; CL: Synthesize

46. 3. If the client agrees, having a visit by a person who has successfully adjusted to living with an ileostomy would be the most helpful measure. This would let the client actually see that typical activities of daily living can be pursued postoperatively. Someone who has felt some of the same concerns can answer the client's questions. A visit from the clergy may be helpful to some clients but would not provide this client with the information sought. Disregarding the client's concerns is not helpful. Although the **healthcare provider (HCP)**  should know about the client's concerns, this in itself will not reassure the client about life after an ileostomy.

CN: Psychosocial adaptation; CL: Synthesize

47. 3. Because of high concentrations of digestive enzymes, ileostomy effluent is irritating to skin and can cause excoriation and ulceration. Some form of protection must be used to keep the effluent from contacting the skin. A skin barrier does not decrease odor formation; odor is controlled by diet. The barrier does not affect the client's hydration status, and the nurse can encourage the client to have an adequate daily intake of fluids. Pouches are usually worn for 4 to 7 days before being changed.

CN: Basic care and comfort; CL: Evaluate

48. 3. Any sudden decrease in drainage or onset of severe abdominal pain should be reported to the **healthcare provider (HCP)**  immediately because it could mean that an obstruction has developed. The ileostomy drains liquid stool at frequent intervals throughout the day. Undigested food may be present at times. A temperature of 99.8°F (37.7°C) is not necessarily abnormal or a cause for concern.

CN: Reduction of risk potential; CL: Synthesize

49. 2. The fact that the client has an ileostomy does not necessarily mean that she cannot get pregnant and bear children. It may be recommended,

however, that the number of pregnancies be limited. Women of childbearing age should be encouraged to discuss their concerns with their **healthcare provider (HCP)** . Discussing their concerns about sexual functioning and pregnancy will help decrease fears and anxiety. Empathizing or telling the woman that she can adopt does not address her concerns. Her current fears may be based on erroneous understanding. Telling the client that she will adjust to the situation ignores her concerns.

 CN: Psychosocial adaptation; CL: Synthesize

50. 3. To maintain an adequate fluid balance, the client needs to drink at least 3,000 mL/day. Heavy lifting should be avoided; the **healthcare provider (HCP)**  will indicate when the client can participate in sports again. The client will not resume working as soon as 2 weeks after surgery. Water does not harm the stoma, so the client does not have to worry about getting it wet.

 CN: Physiological adaptation; CL: Evaluate

51. 4. Sudden onset of abdominal cramps, vomiting, and watery discharge with no stool from an ileostomy are likely indications of an obstruction. It is imperative that the **healthcare provider (HCP)**  examine the client immediately. Although the client is vomiting, the client should not take an antiemetic until the HCP has examined the client. If an obstruction is present, ingesting fluids or taking milk of magnesia will increase the severity of symptoms. Oral intake is avoided when a bowel obstruction is suspected.

 CN: Reduction of risk potential; CL: Synthesize

The Client Receiving Total Parenteral Nutrition

52. 3. The nurse should first obtain a prescription to obtain a culture specimen. The presence of drainage is a potential indication of an infection and the catheter may need to be removed. A culture specimen should be obtained and sent for analysis so that treatment can be promptly initiated. Since removing the catheter will be required in the presence of an infection, the nurse would not clean and redress the area. While the body temperature may increase indicating an infection, a culture needs to be obtained to identify the causative organism. After the culture report is obtained, the nurse

should notify the **healthcare provider (HCP)**  and document all assessments and client care activities in the client's record.

 CN: Safety and infection control; CL: Synthesize

53. 2 Total parenteral nutrition (TPN) is a hypertonic, high-calorie, high-protein intravenous (IV) fluid that should be provided for clients who do not have functional gastrointestinal track motility, in order to better meet metabolic needs of the client and to support optimal nutrition and healing. TPN is prescribed once daily, based on the client's current electrolyte and fluid balance, and must be handled with strict aseptic technique (due to the high glucose content, it is a perfect medium for bacterial growth). Also, because of the high tonicity, TPN must be administered through a central venous access, not a peripheral IV line. There is no specific need to auscultate for bowel sounds to determine whether TPN can safely be administered.

 CN: Pharmacological and parenteral therapies; CL: Synthesize

54. 1. When using a sliding scale insulin schedule, the nurse obtains a glucometer reading of the client's blood glucose level immediately before giving the insulin and bases the dosage on those findings. The fasting blood glucose level obtained earlier in the day is not relevant to an evening sliding scale insulin dosage. The nurse cannot calculate insulin dosage by assessing the amount of TPN intake or dietary intake.

 CN: Pharmacological and parenteral therapies; CL: Synthesize

55. 2. The TPN solution is usually a hypertonic dextrose solution. The greater the concentration of dextrose in the solution, the greater the tonicity. Hypertonic dextrose solutions are used to meet the body's calorie demands in a volume of fluid that will not overload the cardiovascular system. An isotonic dextrose solution (e.g., 5% dextrose in water) or a hypotonic dextrose solution will not provide enough calories to meet metabolic needs. Colloids are plasma expanders and blood products and are not used in TPN.

 CN: Pharmacological and parenteral therapies; CL: Apply

56. 4. The client should be asked to perform the Valsalva maneuver (take a deep breath and hold it) during insertion and removal of a CVAD. This

increases central venous pressure during the procedure and prevents air embolism. Trendelenburg is the preferred position for CVAD insertion and removal. If not possible, supine position is sufficient for CVAD removal. The client should hold the breath, not exhale.

CN: Physiological integrity; CL: Apply

57. 1. The goal of TPN is to meet the client's nutritional needs. TPN is not used to treat metabolic acidosis; ketoacidosis can actually develop as a result of administering TPN. TPN is a hypertonic solution containing carbohydrates, amino acids, electrolytes, trace elements, and vitamins. It is not used to meet the hydration needs of clients. TPN is administered to provide a positive nitrogen balance.

CN: Pharmacological and parenteral therapies; CL: Evaluate

58. 4. During TPN administration, the client should be monitored regularly for hyperglycemia. The client may require small amounts of insulin to improve glucose metabolism. The client should also be observed for signs and symptoms of hypoglycemia, which may occur if the body overproduces insulin in response to a high glucose intake or if too much insulin is administered to help improve glucose metabolism. Tachycardia or hypertension is not indicative of the client's ability to metabolize the solution. An elevated blood urea nitrogen concentration is indicative of renal status and fluid balance.

CN: Pharmacological and parenteral therapies; CL: Analyze

59. 1,2,4. Complications associated with administration of TPN through a central line include infection and air embolism. To prevent these complications, strict aseptic technique is used for all dressing changes, the insertion site is covered with an air-occlusive dressing, and all connections of the system must be secure. Ambulation and activities of daily living are encouraged and not limited during the administration of TPN.

CN: Pharmacological and parenteral therapies; CL: Synthesize

60. 1. The administration of fat emulsion solution provides additional calories and essential fatty acids to meet the body's energy needs. Fatty acids are lipids, not carbohydrates. Fatty acids do not aid in the metabolism of

glucose. Although they are necessary for meeting the complete nutritional needs of the client, fatty acids do not necessarily help a client maintain normal body weight.

CN: Pharmacological and parenteral therapies; CL: Apply

61. 4. An elevated temperature can be an indication of an infection at the insertion site or in the catheter. Vital signs should be taken every 2 to 4 hours after initiation of TPN therapy to detect early signs of complications. Glycosuria is to be expected during the first few days of therapy until the pancreas adjusts by secreting more insulin. A gradual weight gain is to be expected as the client's nutritional status improves. Some clients experience a decreased appetite during TPN therapy.

CN: Reduction of risk potential; CL: Analyze

62. 2. Too rapid infusion of a TPN solution can lead to circulatory overload. The client should be assessed carefully for indications of excessive fluid volume. A negative nitrogen balance occurs in nutritionally depleted individuals, not when TPN fluids are administered in excess. When TPN is administered too rapidly, the client is at risk for receiving an excess of dextrose and electrolytes. Therefore, the client is at risk for hyperglycemia and hyperkalemia.

CN: Pharmacological and parenteral therapies; CL: Analyze

The Client with Diverticular Disease

63. 1,2,4. Clients with diverticulosis are encouraged to follow a high-fiber diet. Bran, broccoli, and navy beans are foods high in fiber. Tomato juice and cheese are low-residue foods.

CN: Reduction of risk potential; CL: Apply

64. 3. The nurse should first assess the client for signs of peritonitis. Complications of diverticulitis include perforation with peritonitis, abscess, and fistula formation; bowel obstruction; ureteral obstruction; and bleeding. A computed tomography (CT) scan with oral contrast is the test of choice for diverticulitis. A client with acute diverticulitis does not receive a barium enema or colonoscopy because of the possibility of peritonitis and

perforation. With acute diverticulitis, the goal of treatment is to allow the colon to rest and inflammation to subside. The client is kept on NPO status; parenteral fluid therapy is provided.

CN: Physiological adaptation; CL: Synthesize

65. 1. Barium enemas and colonoscopies are contraindicated in clients with acute diverticulitis because they can lead to perforation of the colon and peritonitis. A barium enema may be prescribed after the client has been treated with antibiotic therapy and the inflammation has subsided. A barium enema is diagnostic in diverticulitis. A barium enema could increase the client's pain; however, that is not a reason for excluding this test. The client may be able to tolerate the procedure, but the concern is the potential for perforation of the intestine.

CN: Reduction of risk potential; CL: Apply

66. 4. Clients with diverticular disease should refrain from any activities, such as lifting, straining, or coughing, that increase intra-abdominal pressure and may precipitate an attack. Enemas are contraindicated because they increase intestinal pressure. Fluid intake should be increased, rather than decreased, to promote soft, formed stools. A low-fiber diet is used when inflammation is present.

CN: Reduction of risk potential; CL: Synthesize

67. 3,4,5. Clients who have diverticulosis should be instructed to maintain a diet high in fiber and, unless contraindicated, should increase their fluid intake to a minimum of 2,000 mL/day. Participating in a regular exercise program is also strongly encouraged. Diverticulosis can be controlled with treatment but cannot be cured. Clients should be instructed to avoid the regular use of cathartic laxatives. Bulk laxatives and stool softeners may be helpful to maintain regularity and decrease straining.

CN: Reduction of risk potential; CL: Evaluate

68. 1. Diverticular disease is treated with a high-fiber diet and bulk laxatives such as psyllium hydrophilic mucilloid. Fiber decreases the intraluminal pressure and makes it easier for stool to pass through the colon. Bulk laxatives do not manage diarrhea or relieve gas formation. The stool

should remain soft and easy to expel.

CN: Pharmacological and parenteral therapies; CL: Evaluate

69. 1,2,3,5. Percussion will show resonance and tympany indicating paralytic ileus. Lack of liver dullness may indicate free air in the abdomen. The client with peritonitis will have fever, tachypnea, and tachycardia. The abdomen becomes rigid with rebound tenderness, and there will be absent bowel sounds. The client will not demonstrate excessive thirst but may have anorexia, nausea, and vomiting as peristalsis decreases.

CN: Physiological adaptation; CL: Analyze

The Client with Appendicitis

70. 4. The nurse should gently clean the area around the drain by moving in a circular motion away from the drain. Doing so prevents the introduction of microorganisms to the wound and drain site. The incision cannot be left open to air as long as the drain is intact. The nurse should note the amount and character of wound drainage, but the surgeon will determine when the drain should be removed. Surgical wound drains are not irrigated.

CN: Safety and infection control; CL: Synthesize

71. 1. Appendicitis typically begins with periumbilical pain followed by anorexia, nausea, and vomiting. The pain is persistent and continuous, eventually shifting to the right lower quadrant and localizing at McBurney point (located halfway between the umbilicus and the right iliac crest). To relieve pain prior to surgery, the nurse assists the client to a comfortable position with the knees drawn to the chest and the head of the bed slightly elevated. The nurse may also administer analgesics and ice packs, if prescribed; heat is avoided as heat may precipitate rupture of the appendix. The abdomen is not palpated or massaged more than necessary to avoid increasing the pain. Distraction with music may be helpful, but positioning, using ice packs, and analgesics are most effective.

CN: Physiological adaptation; CL: Synthesize

72. 2. Noting the client's first bowel movement after surgery is important because this indicates that normal peristalsis has returned. Sitz baths are used

after rectal surgery, not appendectomy. Ambulation is started the day of surgery and is not confined to bathroom privileges. The abdomen should be auscultated for bowel sounds and palpated for softness, but there is no need to measure the girth every 2 hours.

CN: Physiological adaptation; CL: Synthesize

73. 2. Drains are inserted postoperatively in appendectomies when an abscess was present or the appendix was perforated. The purpose is to promote drainage of exudate from the wound and facilitate healing. A drain is not used for irrigation of the wound. The drain will not minimize scar tissue development or decrease postoperative discomfort.

CN: Reduction of risk potential; CL: Apply

The Client with an Inguinal Hernia

74. 3. The symptoms are indicative of a strangulated hernia. In a strangulated hernia, the hernia cannot be reduced back into the abdominal cavity. The intestinal lumen and the blood supply to the intestine are obstructed, causing an acute intestinal obstruction. Without immediate intervention, necrosis and gangrene may develop. Surgery is required to release the strangulation. Although many of these signs and symptoms are present with peritonitis or perforated bowel, abdominal rigidity, a cardinal sign of peritonitis and perforated bowel, is not mentioned. Therefore, the nurse would not immediately suspect these conditions. An incarcerated hernia refers to a hernia that is irreducible but has not necessarily resulted in an obstruction.

CN: Physiological adaptation; CL: Analyze

75. 4. The client is instructed to avoid lifting items heavier than 5 lb for 4 to 6 weeks following hernia repair. The client continues to take deep breaths and expand the lungs but is instructed to avoid coughing. Ice, rather than heat, is used to reduce scrotal swelling. The client is instructed to sneeze with the mouth open to avoid sudden stress on the sutures.

CN: Physiological adaptation; CL: Apply

76. 4. The most common complication after an inguinal hernia repair is the

inability to void, especially in men. The nurse should evaluate the client carefully for urine retention. Hypostatic pneumonia, deep vein thrombosis, and paralytic ileus are potential postoperative problems with any surgical client but are not as likely to occur after an inguinal hernia repair as is urine retention.

 CN: Reduction of risk potential; CL: Analyze

Managing Care, Quality, and Safety of Clients with Lower Gastrointestinal Tract Health Problems

77. 2. The nurse administers the PRBCs using a separate infusion line and appropriate tubing, with normal saline as the priming solution. It is not necessary to discontinue the TPN infusion or wait until the TPN infusion is completed.

 CN: Safety and infection control; CL: Synthesize

78. 2,5. The nurse should consider client needs and scope of practice when assigning staff to provide care. The client who is recovering from inguinal hernia repair surgery and the client who is experiencing an exacerbation of ulcerative colitis are appropriate clients to assign to an **LPN/VN** as the care they require falls within the scope of practice for an LPN or a VN. It is not within the scope of practice for the LPN/VN to administer TPN, insert nasoenteric tubes, or provide client teaching related to medications.

 CN: Management of care; CL: Synthesize

79. 2,4,5. The nurse can delegate the following basic care activities to the **UAP** : providing skin care following bowel movements, maintaining intake and output records, and obtaining the client's weight. Assessing the client's bowel sounds and evaluating the client's response to medication are **registered nurse (RN)** activities that cannot be delegated.

 CN: Management of care; CL: Synthesize

80. 3. This client has signs and symptoms of severe sepsis. Blood cultures should be drawn prior to administering the antibiotic (vancomycin); and the antibiotics should be administered within the first 45 minutes after recognition of these signs in order to try to prevent septic shock. Obtaining a

chest x-ray and inserting a urinary catheter to accurately measure intake and output are also important actions but are not first priority for this client.

CN: Reduction of risk potential; CL: Synthesize

81. 4,5. *Clostridium difficile* is an organism that has developed very resistant and highly morbid strains. Universal precautions, most importantly handwashing, wearing personal protective gear, and modest use of antibiotics, are critical actions for stopping the spread. *C. difficile* is not spread via the respiratory tract; therefore, a mask is not needed. Alcohol-based hand sanitizers do not kill the spores of *C. difficile*; soap and water must be used. Sterile gloves are not needed to provide care; clean gloves may be worn.

CN: Safety and infection control; CL: Synthesize

82. 4. When TPN fluids are infused too rapidly or too slowly, the HCP  should be notified. TPN solutions must be carefully and accurately infused. Rate adjustments should not be made without a written prescription from the HCP. Significant alterations in rate (10% increase or decrease) can result in fluctuations of blood glucose levels. Speeding up the solution can result in too much glucose entering the system.

CN: Management of care; CL: Synthesize

83. 3. The nurse should contact the pharmacy directly and request that a properly labeled medication be provided. The nurse should not administer any drug that is not properly labeled, even if the nurse or another nurse recognizes the medication. It is not necessary to notify the unit manager at this point because the client needs to receive the antibiotic as soon as possible.

CN: Safety and infection control; CL: Apply

84. 3. When dehiscence occurs, the nurse should immediately cover the wound with a sterile dressing moistened with normal saline. If the dehiscence is extensive, the incision must be resutured in surgery. Later, after the sutures are removed, additional support may be provided to the incision by applying strips of tape as directed by institutional policy or by the surgeon. An abdominal binder may also be utilized for additional support.

CN: Reduction of risk potential; CL: Synthesize

85. 2. Airborne precautions are required for clients with presumed or proven pulmonary tuberculosis (TB), chickenpox, or other airborne pathogens. Contact precautions are used for organisms that are spread by skin-to-skin contact, such as antibiotic-resistant organisms or *Clostridium difficile*. Droplet precautions are used for organisms such as influenza or *meningococcus* that can be transmitted by close respiratory or mucous membrane contact with respiratory secretions. The most important aspect of reducing the risk of bloodborne infection is avoidance of percutaneous injury. Extreme care is essential when needles, scalpels, and other sharp objects are handled.

CN: Safety and infection control; CL: Apply

86. 2,4. A black box warning for ciprofloxacin is that ciprofloxacin may increase the anticoagulant effects of warfarin. The nurse should instruct the client to report increased bleeding and to monitor the prothrombin time (PT) and the international normalized ratio (INR) closely. Although there is a drug-food interaction and taking ciprofloxacin may increase the stimulatory effect of caffeine, the client does not need to eliminate caffeine, but should report signs of stimulant effect. Ciprofloxacin may cause photosensitivity reactions; the nurse must advise the client to avoid excessive sunlight or artificial ultraviolet light during therapy. Clients must be advised not to crush, split, or chew the extended-release tablets. It is not necessary to increase the amount of fluids.

CN: Pharmacological and parenteral therapies; CL: Synthesize

The Client with Biliary Tract Disorders

- The Client with Cholecystitis
- The Client with Pancreatitis
- The Client with Viral Hepatitis
- The Client with Cirrhosis
- Managing Care, Quality, and Safety of Clients with Biliary Tract Disorders
- Answers, Rationales, and Test-Taking Strategies

The Client with Cholecystitis

1. A client has undergone a laparoscopic cholecystectomy. Which instruction should the nurse include in the discharge teaching?

- ☐ **1.** Empty the bile bag daily.
- ☐ **2.** Breathe deeply into a paper bag when nauseated.
- ☐ **3.** Keep adhesive dressings in place for 6 weeks.
- ☐ **4.** Report bile-colored drainage from any incision.

2. A 40-year-old client is admitted to the hospital with a diagnosis of acute cholecystitis. The nurse should contact the healthcare provider (HCP) to question which prescription?

- ☐ **1.** IV fluid therapy of normal saline solution to be infused at 100 mL/h until further prescriptions.
- ☐ **2.** Administer morphine sulfate 10 mg IM every 4 hours as needed for severe abdominal pain.
- ☐ **3.** Nothing by mouth (NPO) until further prescriptions.
- ☐ **4.** Insert a nasogastric tube, and connect to low intermittent suction.

3. A client is admitted to the hospital with a diagnosis of cholecystitis from

cholelithiasis. The client has severe abdominal pain and nausea and has vomited 120 mL. Based on these data, which nursing action would have the **highest priority** at this time?

- ☐ 1. Manage anxiety.
- ☐ 2. Restore fluid loss.
- ☐ 3. Manage the pain.
- ☐ 4. Replace nutritional loss.

4. A client's stools are light gray in color. For what finding should the nurse assess the client? Select all that apply.

- ☐ 1. intolerance to fatty foods
- ☐ 2. fever
- ☐ 3. jaundice
- ☐ 4. respiratory distress
- ☐ 5. pain at McBurney's point
- ☐ 6. peptic ulcer disease

5. A client who has been scheduled to have a choledocholithotomy expresses anxiety about having surgery. Which nursing intervention would be the **most** appropriate to achieve the outcome of anxiety reduction?

- ☐ 1. providing the client with information about what to expect postoperatively
- ☐ 2. telling the client not to be afraid
- ☐ 3. reassuring the client by saying that surgery is a common procedure
- ☐ 4. stressing the importance of following the healthcare provider's (HCP's) instructions after surgery

6. A client has an open cholecystectomy with bile duct exploration. Following surgery, the client has a T tube. To evaluate the effectiveness of the T tube, the nurse should:

- ☐ 1. irrigate the tube with 20 mL of normal saline every 4 hours.
- ☐ 2. unclamp the T tube and empty the contents every day.
- ☐ 3. assess the color and amount of drainage every shift.
- ☐ 4. monitor the multiple incision sites for bile drainage.

7. At 0800, the nurse reviews the amount of T-tube drainage for a client

who underwent an open cholecystectomy yesterday. After reviewing the output record (see chart), the nurse should:

Output Record

Time	T-Tube
1200	50 mL
1600	60 mL
2000	60 mL
0000	70 mL
0400	70 mL
0800	10 mL

- ☐ 1. report the 24-hour drainage amount at 1200.
- ☐ 2. clamp the T tube.
- ☐ 3. evaluate the tube for patency.
- ☐ 4. irrigate the T tube.

8. The nurse measures the amount of bile drainage from a T tube and records it by which method?

- ☐ 1. adding it to the client's urine output
- ☐ 2. charting it separately on the output record
- ☐ 3. adding it to the amount of wound drainage
- ☐ 4. subtracting it from the total intake for each day

9. The nurse is caring for a client who had an open cholecystectomy 24 hours ago. The client's vital signs have been stable over the last 24 hours, with most recent temperature 98.6°F (37°C), blood pressure (BP) 118/76 mm Hg, respiratory rate (RR) 16/minute, and heart rate (HR) 78 bpm, but are now changing. Which set of vital signs indicates that the nurse should contact the

healthcare provider (HCP)?

- ☐ 1. temperature 101.8°F (38.8°C), BP 140/86 mm Hg, HR 94 bpm, RR 24/min
- ☐ 2. temperature 100.7°F (38.2°C), BP 118/68 mm Hg, HR 84 bpm, RR 20/min
- ☐ 3. temperature 99.5°F (37.5°C), BP 126/80 mm Hg, HR 58 bpm, RR 16/min
- ☐ 4. temperature 97.5°F (36.4°C), BP 98/64 mm Hg, HR 98 bpm, RR 18/min

10. After a cholecystectomy, the client is to follow a low-fat diet. Which food would be **most** appropriate to include in a low-fat diet?

- ☐ 1. cheese omelet with onions
- ☐ 2. peanut butter on wheat toast
- ☐ 3. ham salad sandwich made with mayonnaise
- ☐ 4. roast beef sandwich with lettuce and tomato

11. A client with cholecystitis continues to have severe right upper quadrant pain. The nurse obtains the following vital signs: temperature 101.1°F (38.4°C); pulse 114 bpm; respirations 22/min; blood pressure 142/90 mm Hg. Using the SBAR (Situation-Background-Assessment-Recommendation) technique for communication, the nurse recommends to the healthcare provider for the client to receive:

- ☐ 1. hydromorphone IV.
- ☐ 2. diltiazem PO.
- ☐ 3. meperidine IM.
- ☐ 4. promethazine IM.

12. The nurse prepares to administer promethazine 35 mg IM as prescribed PRN for a client with cholecystitis who has nausea. The ampule label reads that the medication is available in 25 mg/mL. How many milliliters should the nurse administer? Record your answer using one decimal place.

_____ ml.

13. A client undergoes a laparoscopic cholecystectomy. Which dietary

instructions should the nurse give the client immediately after surgery?

- ☐ 1. "You cannot eat or drink anything for 24 hours."
- ☐ 2. "You may resume your normal diet the day after your surgery."
- ☐ 3. "Drink liquids today and eat lightly for a few days."
- ☐ 4. "You can progress from a liquid to a bland diet as tolerated."

14. Which discharge instruction would be appropriate for a client who has had a laparoscopic cholecystectomy and has sutures covered by a dressing?

- ☐ 1. Avoid showering for 1 week after surgery.
- ☐ 2. Return to work within 1 week.
- ☐ 3. Leave dressing in place until you see the surgeon at the postoperative visit.
- ☐ 4. Use acetaminophen to control any fever.

15. A client who has had a laparoscopic cholecystectomy has adhesive strips over the puncture sites. When preparing the client for discharge, which client statements indicate that the teaching has been successful? Select all that apply.

- ☐ 1. "I can resume my normal diet when I want."
- ☐ 2. "I need to avoid driving for about 4 weeks."
- ☐ 3. "I may experience some pain in my right shoulder."
- ☐ 4. "I should spend 2 to 3 days in bed before resuming activity."
- ☐ 5. "I can take a shower 2 days later."

16. A client has been admitted to the medical surgical unit following an emergency cholecystectomy. There is a Jackson-Pratt drain with a portable suction unit attached. After 4 hours, the drainage unit is full. What should the nurse do?

- ☐ 1. Notify the surgeon.
- ☐ 2. Remove the drain and suction unit.
- ☐ 3. Check the dressing for bleeding.
- ☐ 4. Empty the drainage unit.

The Client with Pancreatitis

17. The client who has been hospitalized with pancreatitis does not drink alcohol because of religious convictions. The client comes upset when the healthcare provider (HCP) persists in asking about alcohol intake. The nurse should explain that the reason for these questions is that:

- ☐ **1.** there is a strong link between alcohol use and acute pancreatitis.
- ☐ **2.** alcohol intake can interfere with the tests used to diagnose pancreatitis.
- ☐ **3.** alcoholism is a major health problem, and all clients are questioned about alcohol intake.
- ☐ **4.** the HCP must obtain the pertinent facts, regardless of religious beliefs.

18. A client with acute pancreatitis has a blood pressure of 88/40 mm Hg, heart rate of 128 bpm, respirations of 28/min, and Grey Turner's sign. What prescription should the nurse implement **first**?

- ☐ **1.** Initiate intake/output record.
- ☐ **2.** Place an intravenous line.
- ☐ **3.** Position on the left side.
- ☐ **4.** Insert a nasogastric tube.

19. On 1/16 at 0800, the nurse is caring for a client with acute pancreatitis and reviewing progress notes as listed:

Nurses Progress Notes

Date	Time	Progress Notes
1/15	0800	Vital signs are: temperature 37.4°C; heart rate, 138; BP is 80/48; pain is 9 on a 10-point scale; client is restless. Robin Brown, RN
1/15	1000	Discussed following lab values with A. Smith, MD: hematocrit is 27.6%, hemoglobin is 7.6 g/dl, platelet count is 245,000 mm ³ , and INR is 0.8. Robin Brown, RN
1/15	1100	PRBCs infused; no adverse reactions. Robin Brown, RN

Which finding indicates that the desired outcome of the transfusion is obtained at this time?

- ☐ 1. BP is 110/80 mm Hg.
- ☐ 2. Pain is 4 on a 10-point scale.
- ☐ 3. Hemoglobin is 12 g/dL.
- ☐ 4. Platelet count is 144,000/mm³.

20. The nurse should question which prescription for medications for a client with acute pancreatitis?

- ☐ 1. furosemide 20 mg IV push
- ☐ 2. imipenem 500 mg IV

- ☐ 3. morphine sulfate 2 mg IV push
- ☐ 4. famotidine 20 mg IV push

21. The nurse should monitor the client with acute pancreatitis for which complication?

- ☐ 1. heart failure
- ☐ 2. duodenal ulcer
- ☐ 3. cirrhosis
- ☐ 4. pneumonia

22. When providing care for a client hospitalized with acute pancreatitis who has acute abdominal pain, which nursing intervention(s) would be **most** appropriate for this client? Select all that apply.

- ☐ 1. Place the client in a side-lying position.
- ☐ 2. Administer morphine sulfate for pain as needed.
- ☐ 3. Maintain the client on a high-calorie, high-protein diet.
- ☐ 4. Monitor the client's respiratory status.
- ☐ 5. Obtain daily weights.

23. The nurse notes that a client with acute pancreatitis occasionally experiences muscle twitching and jerking. How should the nurse interpret the significance of these symptoms?

- ☐ 1. The client may be developing hypocalcemia.
- ☐ 2. The client is experiencing a reaction to meperidine.
- ☐ 3. The client has a nutritional imbalance.
- ☐ 4. The client needs a muscle relaxant to promote rest.

24. A client is receiving propantheline bromide in the management of acute pancreatitis. Which finding would indicate that the nurse should discuss withholding the medication with the healthcare provider (HCP)?

- ☐ 1. absent bowel sounds
- ☐ 2. increased urine output
- ☐ 3. diarrhea
- ☐ 4. decreased heart rate

25. Which dietary instruction would be appropriate for the nurse to give a

client who is recovering from acute pancreatitis?

- ☐ 1. Avoid crash dieting.
- ☐ 2. Restrict carbohydrate intake.
- ☐ 3. Eat six small meals a day.
- ☐ 4. Decrease sodium in the diet.

26. Pancreatic enzyme replacements are prescribed for the client with chronic pancreatitis. When should the nurse instruct the client to take them to obtain the most therapeutic effect?

- ☐ 1. three times daily between meals
- ☐ 2. with each meal and snack
- ☐ 3. in the morning and at bedtime
- ☐ 4. every 4 hours, at specified times

27. The nurse should teach the client with chronic pancreatitis to monitor the effectiveness of pancreatic enzyme replacement therapy by:

- ☐ 1. recording daily fluid intake.
- ☐ 2. performing glucose fingerstick tests twice a day.
- ☐ 3. observing stools for steatorrhea.
- ☐ 4. testing urine for ketones.

28. The nurse is assessing a client with chronic hepatitis B who is receiving lamivudine. What information is **most** important to communicate to the healthcare provider (HCP)?

- ☐ 1. The client has had a 3-kg weight gain over 2 days.
- ☐ 2. The client has nausea.
- ☐ 3. The client now has a temperature of 99°F (37.2°C) orally.
- ☐ 4. The client has fatigue.

The Client with Viral Hepatitis

29. The nurse is assessing a client with hepatitis A and notices that the aspartate transaminase (AST) and alanine transaminase (ALT) lab values have increased. Which statement by the client indicates the need for further instruction by the nurse?

- ☐ 1. "I require increased periods of rest."
- ☐ 2. "I follow a low-fat, high-carbohydrate diet."
- ☐ 3. "I eat dry toast to relieve my nausea."
- ☐ 4. "I take acetaminophen for arthritis pain."

30. College freshmen are participating in a study abroad program. When teaching them about hepatitis B, the nurse should instruct the students on the need for:

- ☐ 1. water sanitation.
- ☐ 2. single dormitory rooms.
- ☐ 3. vaccination for hepatitis D.
- ☐ 4. safe sexual practices.

31. Which finding is normal for a client during the icteric phase of hepatitis A?

- ☐ 1. tarry stools
- ☐ 2. yellowed sclerae
- ☐ 3. shortness of breath
- ☐ 4. light, frothy urine

32. The nurse is teaching a client with hepatitis A about preventing transmission of the disease. The nurse should focus teaching on:

- ☐ 1. proper food handling.
- ☐ 2. insulin syringe disposal.
- ☐ 3. alpha-interferon.
- ☐ 4. use of condoms.

33. A client has a positive serologic test for anti-HCV (hepatitis C virus). The nurse should instruct the client:

- ☐ 1. how to self-administer alpha-interferon.
- ☐ 2. that the HCV will resolve in approximately 3 months.
- ☐ 3. that a follow-up appointment for HCV genotype testing is required.
- ☐ 4. to take alpha-interferon as prescribed.

34. A client with chronic hepatitis C is experiencing nausea, anorexia, and fatigue. During the health history, the client states that he is homosexual,

drinks one to two glasses of wine with dinner, is taking St. John's wort for a "bit of depression," and takes acetaminophen for frequent headaches. What should the nurse do? Select all that apply.

- ☐ 1. Instruct the client that the wine with meals can be beneficial for cardiovascular health.
- ☐ 2. Instruct the client to ask the healthcare provider (HCP) about taking any other medications as they may interact with medications the client is currently taking.
- ☐ 3. Instruct the client to increase the protein in his diet and eat less frequently.
- ☐ 4. Advise the client of the need for additional testing for HIV.
- ☐ 5. Encourage the client to obtain sufficient rest.

35. A client who is recovering from hepatitis A has fatigue and malaise. The client asks the nurse, "When will my strength return?" Which response by the nurse is **most** appropriate?

- ☐ 1. "Your fatigue should be gone by now. We will evaluate you for a secondary infection."
- ☐ 2. "Your fatigue is an adverse effect of your drug therapy. It will disappear when your treatment regimen is complete."
- ☐ 3. "It is important for you to increase your activity level. That will help decrease your fatigue."
- ☐ 4. "It is normal for you to feel fatigued. The fatigue should go away in the next 2 to 4 months."

36. The nurse is caring for a client recently diagnosed with hepatitis C. In reviewing the client's history, what information will be **most** helpful as the nurse develops a teaching plan? The client:

- ☐ 1. has a history of exercise-induced asthma.
- ☐ 2. is a scientist and is frequently exposed to multiple chemicals.
- ☐ 3. traveled to Central America recently and ate uncooked vegetables.
- ☐ 4. has a known history of sexually transmitted disease.

37. A client recently diagnosed with hepatitis C states: "Now that you know what is wrong with me, you can just get me those new drugs to take care of it, right?" The nurse should tell the client:

- ☐ 1. “The treatment is complex. There are new antiviral drugs available that may make treatment more effective and help you tolerate it better.”
- ☐ 2. “There are drugs to help with the symptoms, but once you have hepatitis C you will never be cured.”
- ☐ 3. “The medicine currently used to treat hepatitis C is very expensive, and your insurance probably will not pay for it.”
- ☐ 4. “If you continue to make the same lifestyle choices, the medicine will not make any difference.”

38. The nurse is developing a plan of care for the client with viral hepatitis. The nurse should instruct the client to:

- ☐ 1. obtain adequate bed rest.
- ☐ 2. increase fluid intake.
- ☐ 3. take antibiotic therapy as prescribed.
- ☐ 4. drink 8 oz (240 mL) of an electrolyte solution every day.

39. When planning care for a client with hepatitis A, the nurse should review laboratory reports for which laboratory values?

- ☐ 1. prolonged prothrombin time
- ☐ 2. decreased blood glucose level
- ☐ 3. elevated serum potassium level
- ☐ 4. decreased serum calcium level

40. The nurse should teach the client with hepatitis A to:

- ☐ 1. limit caloric intake and reduce weight.
- ☐ 2. increase carbohydrates and protein in the diet.
- ☐ 3. avoid contact with others and sleep in a separate room.
- ☐ 4. intensify routine exercise and increase strength.

41. The nurse develops a teaching plan for the client about how to prevent the transmission of hepatitis A. Which discharge instruction is appropriate for the client?

- ☐ 1. Spray the house to eliminate infected insects.
- ☐ 2. Tell family members to try to stay away from the client.
- ☐ 3. Ask family members to wash their hands frequently.

- ☐ 4. Disinfect all clothing and eating utensils.

42. The client with hepatitis A is experiencing fatigue, weakness, and a general feeling of malaise. The client tires rapidly during morning care. The **most** appropriate goal for this client is to:

- ☐ 1. increase mobility.
- ☐ 2. learn new self-care skills.
- ☐ 3. adapt to new levels of energy.
- ☐ 4. gradually increase activity tolerance.

43. Interferon alfa-2b has been prescribed to treat a client with chronic hepatitis B. The nurse should assess the client for which common adverse effect?

- ☐ 1. retinopathy
- ☐ 2. constipation
- ☐ 3. flulike symptoms
- ☐ 4. hypoglycemia

44. The nurse is preparing a community education program about preventing hepatitis B infection. Which information should be incorporated into the teaching plan?

- ☐ 1. Hepatitis B is relatively uncommon among college students.
- ☐ 2. Frequent ingestion of alcohol can predispose an individual to development of hepatitis B.
- ☐ 3. Good personal hygiene habits are most effective at preventing the spread of hepatitis B.
- ☐ 4. The use of a condom is advised for sexual intercourse.

45. Which goal is appropriate for a client with hepatitis A? The client will:

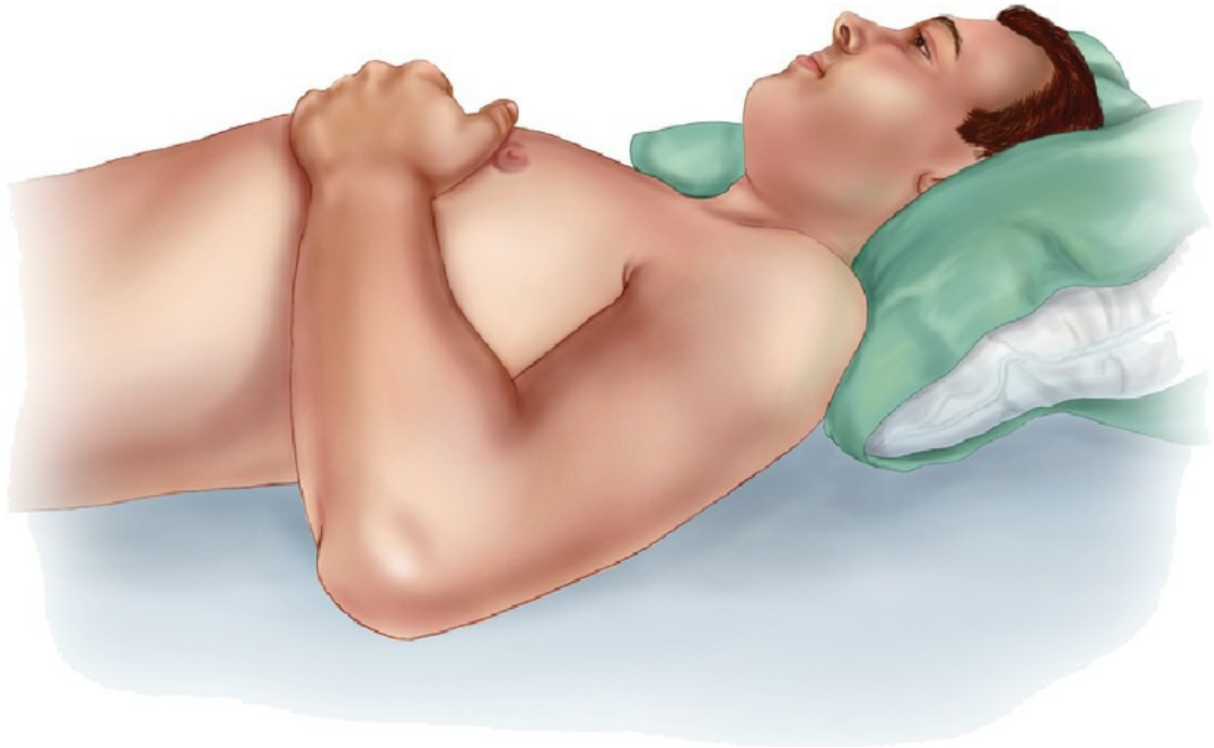

- ☐ 1. demonstrate a decrease in fluid retention related to ascites.
- ☐ 2. verbalize the importance of reporting bleeding gums or bloody stools.
- ☐ 3. limit use of alcohol to two to three drinks per week.
- ☐ 4. restrict activity to within the home to prevent disease transmission.

The Client with Cirrhosis

46. A client had a liver biopsy 1 hour ago. The nurse should **first**:

- ☐ 1. auscultate lung sounds.
- ☐ 2. check for fever.
- ☐ 3. obtain a CBC.
- ☐ 4. apply packing to the biopsy site.

47. The nurse is assessing a client for ascites. Where does the nurse place the hands to percuss for the presence of fluid?

48. A client with cirrhosis is receiving lactulose. The nurse notes the client is more confused and has asterixis. The nurse should:

- ☐ 1. assess for gastrointestinal (GI) bleeding.
- ☐ 2. withhold the lactulose.
- ☐ 3. increase protein in the diet.
- ☐ 4. monitor serum bilirubin levels.

49. The nurse is assessing a client with cirrhosis who has developed hepatic encephalopathy. The nurse should notify the healthcare provider (HCP) of a decrease in which serum lab value that is a potential precipitating factor for hepatic encephalopathy?

- ☐ 1. aldosterone
- ☐ 2. creatinine
- ☐ 3. potassium
- ☐ 4. protein

50. A client has advanced cirrhosis of the liver. The client's spouse asks the nurse why his abdomen is swollen, making it very difficult for him to fasten his pants. How should the nurse respond to provide the **most** accurate explanation of the disease process?

- ☐ 1. "He must have been eating too many foods with salt in them. Salt pulls water with it."
- ☐ 2. "The swelling in his ankles must have moved up closer to his heart so the fluid circulates better."
- ☐ 3. "He must have forgotten to take his daily water pill."
- ☐ 4. "Blood is not able to flow readily through the liver now, and the liver cannot make protein to keep fluid inside the blood vessels."

51. A nurse is developing a care plan for a client with hepatic encephalopathy. Which are goals for the care for this client? Select all that apply.

- ☐ 1. Prevent constipation.
- ☐ 2. Administer lactulose to reduce blood ammonia levels.
- ☐ 3. Monitor coordination while walking.
- ☐ 4. Check the pupil reaction.
- ☐ 5. Provide food and fluids high in carbohydrate.
- ☐ 6. Encourage physical activity.

52. The nurse is assessing a client who is in the early stages of cirrhosis of the liver. Which focused assessment is appropriate?

- ☐ 1. peripheral edema
- ☐ 2. ascites
- ☐ 3. anorexia
- ☐ 4. jaundice

53. A client with cirrhosis begins to develop ascites. Spironolactone is prescribed to treat the ascites. The nurse should monitor the client closely for

which drug-related adverse effect?

- ☐ 1. constipation
- ☐ 2. hyperkalemia
- ☐ 3. irregular pulse
- ☐ 4. dysuria

54. What diet should be implemented for a client who is in the early stages of cirrhosis?

- ☐ 1. high-calorie, high-carbohydrate
- ☐ 2. high-protein, low-fat
- ☐ 3. low-fat, low-protein
- ☐ 4. high-carbohydrate, low-sodium

55. A client with jaundice has pruritus and areas of irritation from scratching. What measures can the nurse suggest the client use to prevent skin breakdown? Select all that apply.

- ☐ 1. Avoid lotions containing calamine.
- ☐ 2. Add baking soda to the water in a tub bath.
- ☐ 3. Keep nails short and clean.
- ☐ 4. Rub the skin when it itches with knuckles instead of nails.
- ☐ 5. Massage skin with alcohol.
- ☐ 6. Increase sodium intake in diet.

56. Which health promotion activity should the nurse suggest that the client with cirrhosis add to the daily routine at home?

- ☐ 1. Supplement the diet with daily multivitamins.
- ☐ 2. Abstain from drinking alcohol.
- ☐ 3. Take a sleeping pill at bedtime.
- ☐ 4. Limit contact with other people whenever possible.

57. The nurse is reviewing the chart information for a client with increased ascites. The data include the following: temperature 98.9°F (37.2°C), heart rate 118 bpm, shallow respirations 26/min, blood pressure 128/76 mm Hg, and SpO₂ 89% on room air. The nurse should **first**:

- ☐ 1. assess heart sounds.

- ☐ 2. obtain a prescription for blood cultures.
- ☐ 3. prepare for a paracentesis.
- ☐ 4. raise the head of the bed.

58. Which position would be appropriate for a client with severe ascites?

- ☐ 1. Fowler's
- ☐ 2. side-lying
- ☐ 3. reverse Trendelenburg
- ☐ 4. Sims

59. The nurse is caring for a client with esophageal varices. The nurse should discuss which laboratory report finding with the healthcare provider (HCP)?

- ☐ 1. normal serum albumin
- ☐ 2. decreased ammonia
- ☐ 3. slightly decreased levels of calcium
- ☐ 4. elevated PT/INR

60. A client with cirrhosis who has ascites receives 100 mL of 25% serum albumin IV. Which finding would **best** indicate that the albumin is having its desired effect?

- ☐ 1. reduced ascites
- ☐ 2. increased serum albumin level
- ☐ 3. decreased anorexia
- ☐ 4. increased ease of breathing

61. A client with a Sengstaken-Blakemore tube has a sudden drop in SpO₂ and an increase in respiratory rate to 40 breaths/min. What should the nurse do in order from **first** to last? All options must be used.

1. Affirm airway obstruction by the tube.

2. Remove the tube.

3. Deflate the tube by cutting with bedside scissors.

4. Apply oxygen via face mask.

62. The healthcare provider (HCP) instructs a client with alcohol-induced cirrhosis to stop drinking alcohol. The expected outcome of this intervention is:

- ☐ 1. absence of delirium tremens.
- ☐ 2. having a balanced diet.
- ☐ 3. improved liver function.
- ☐ 4. reduced weight.

63. The nurse monitors a client with cirrhosis for the development of hepatic encephalopathy. Which would be an indication that hepatic encephalopathy is developing?

- ☐ 1. decreased mental status
- ☐ 2. elevated blood pressure
- ☐ 3. decreased urine output
- ☐ 4. labored respirations

64. A client's serum ammonia level is elevated, and the healthcare provider (HCP) prescribes 30 mL of lactulose. Which effect is common for this drug?

- ☐ 1. increased urine output
- ☐ 2. improved level of consciousness
- ☐ 3. increased bowel movements
- ☐ 4. nausea and vomiting

65. The nurse has a prescription to administer 2 oz of lactulose to a client who has cirrhosis. How many milliliters of lactulose should the nurse administer? Record your answer using a whole number.

_____ mL.

66. A client is to be discharged with a prescription for lactulose. The nurse teaches the client and the client's spouse how to administer this medication. Which statement would indicate that the client has understood the information?

- ☐ 1. "I will take it with an antacid."
- ☐ 2. "I will mix it with apple juice."
- ☐ 3. "I will take it with a laxative."
- ☐ 4. "I will mix the crushed tablets in some gelatin."

67. The nurse is providing discharge instructions for a client with cirrhosis. Which statement **best** indicates that the client has understood the teaching?

- ☐ 1. "I should eat a high-protein, high-carbohydrate diet to provide energy."
- ☐ 2. "It is safer for me to take acetaminophen for pain instead of aspirin."
- ☐ 3. "I should avoid constipation to decrease chances of bleeding."
- ☐ 4. "If I get enough rest and follow my diet, it is possible for my cirrhosis to be cured."

68. The nurse is preparing a client for a paracentesis. The nurse should:

- ☐ 1. have the client void immediately before the procedure.
- ☐ 2. place the client in a side-lying position.
- ☐ 3. initiate an IV line to administer sedatives.
- ☐ 4. place the client on nothing-by-mouth (NPO) status 6 hours before the procedure.

69. A client with ascites and peripheral edema is at risk for impaired skin integrity. To prevent skin breakdown, the nurse should:

- ☐ 1. institute range-of-motion (ROM) exercise every 4 hours.
- ☐ 2. massage the abdomen once a shift.
- ☐ 3. use an alternating air pressure mattress.

- ☐ 4. elevate the lower extremities.

Managing Care, Quality, and Safety of Clients with Biliary Tract Disorders

70. Which precautions should the healthcare team observe when caring for clients with hepatitis A?

- ☐ 1. gowning when entering a client's room
- ☐ 2. wearing a mask when providing care
- ☐ 3. assigning the client to a private room
- ☐ 4. wearing gloves when giving direct care

71. After completing assessment rounds, which client should the nurse discuss with the healthcare provider (HCP) **first**?

- ☐ 1. a client with cirrhosis who is depressed and has refused to eat for the past 2 days
- ☐ 2. a client with stable vital signs that has been receiving IV ciprofloxacin following a cholecystectomy for 1 day and has developed a rash on the chest and arms
- ☐ 3. a client with pancreatitis whose family requests to speak with the HCP regarding the treatment plan
- ☐ 4. a client with hepatitis whose pulse was 84 bpm and regular and is now 118 bpm and irregular

72. The nurse's assignment consists of four clients. From highest to lowest priority, in which order should the nurse assess the clients after receiving the morning report? All options must be used.

1. the client with cirrhosis who became confused and disoriented during the night

2. the client who is 1 day postoperative following a cholecystectomy and has a T tube inserted

3. the client with acute pancreatitis who is requesting pain medication

4. the client with hepatitis B who has questions about discharge instructions

73. The nurse should institute which measure to prevent transmission of the hepatitis C virus to healthcare personnel?

- ☐ 1. administering hepatitis C vaccine to all healthcare personnel
- ☐ 2. decreasing contact with blood and blood-contaminated fluids
- ☐ 3. wearing gloves when emptying the bed pan
- ☐ 4. wearing a gown and mask when providing direct care

74. The nurse is taking care of a client who has an IV infusion pump. The pump alarm rings. What should the nurse do in order from first to last? All options must be used.

1. Silence the pump alarm.

2. Determine if the infusion pump is plugged into an electrical outlet.

3. Assess the client's access site for infiltration or inflammation.

4. Assess the tubing for hindrances to flow of solution.

Answers, Rationales, and Test-Taking Strategies

*The answers and rationales for each question follow below, along with keys (📖) to the client need (CN) and cognitive level (CL) for each question. In addition, you will also see a glossary icon (🔑) highlighting specific terminology used on the licensing exam. As you check your answers, use the **Content Mastery and Test-Taking Skill Self-Analysis** worksheet (tear-out worksheet in back of book) to identify the reason(s) for not answering the questions correctly. For additional information about test-taking skills and strategies for answering questions, refer to pages 12–23 and pages 35–36 in Part 1 of this book.*

The Client with Cholecystitis

1. 4. There should be no bile-colored drainage coming from any of the incisions postoperatively. A laparoscopic cholecystectomy does not involve a bile bag. Breathing deeply into a paper bag will prevent a person from passing out due to hyperventilation; it does not alleviate nausea. If the adhesive dressings have not already fallen off, they are removed by the surgeon in 7 to 10 days, not 6 weeks.

🔑 CN: Management of care; CL: Create

2. 2. A nurse should question the prescription for morphine sulfate because it is believed to cause biliary spasm. Thus, the preferred opioid analgesic to treat cholecystitis is meperidine. Elderly clients should not be given meperidine because of the risk of acute confusion and seizures in this population. An alternative pain medication will be necessary. IV fluid therapy is used to maintain fluid and electrolyte balance that may result from NPO status and gastric suctioning. NPO status and gastric decompression prevent

further gallbladder stimulation.

CN: Safety and infection control; CL: Synthesize

3. 3. The priority for nursing care at this time is to decrease the client's severe abdominal pain. The pain, which is frequently accompanied by nausea and vomiting, is caused by biliary spasm. Opioid analgesics are given to relieve the severe pain and spasm of cholecystitis. Relief of pain may decrease nausea and vomiting and thereby decrease the client's likelihood of developing further complications, such as severe fluid loss and inadequate nutrition. There are no data to suggest that the client is anxious.

CN: Physiological adaptation; CL: Analyze

4. 1,2,3. Bile is created in the liver, stored in the gallbladder, and released into the duodenum, giving stool its brown color. A bile duct obstruction can cause pale-colored stools. Other symptoms associated with cholelithiasis are right upper quadrant tenderness, fever from inflammation or infection, jaundice from elevated serum bilirubin levels, and nausea or right upper quadrant pain after a fatty meal. Pain at McBurney's point lies between the umbilicus and right iliac crest and is associated with appendicitis. A bleeding ulcer produces black, tarry stools. Respiratory distress is not a symptom of cholelithiasis.

CN: Physiological adaptation; CL: Analyze

5. 1. Providing information can help to answer the client's questions and decrease anxiety. Fear of the unknown can increase anxiety. Telling the client not to be afraid, that the procedure is common, or to follow the **HCP's**  prescriptions will not necessarily decrease anxiety.

CN: Psychosocial adaptation; CL: Synthesize

6. 3. A T tube is inserted in the common bile duct to maintain patency when there is a likelihood of edema. The tube remains in place until edema from the duct exploration subsides. The bile color should be gold to dark green, and the amount of drainage should be closely monitored to ensure tube patency. Irrigation is not routinely done, unless prescribed using a smaller volume of fluid. The T tube is not clamped in the early post-op period to allow for continuous drainage. An open cholecystectomy has one right

subcostal incision, whereas a laparoscopic cholecystectomy has multiple small incisions.

CN: Physiological adaptation; CL: Evaluate

7. 3. The T tube should drain approximately 300 to 500 mL in the first 24 hours, and after 3 to 4 days, the amount should decrease to <200 mL in 24 hours. With the sudden decrease in drainage at 0800, the nurse should immediately assess the tube for obstruction of flow that can be caused by kinks in the tube or the client lying on the tube. Drainage color must also be assessed for signs of bleeding. The tube should not be irrigated or clamped without a prescription.

CN: Physiological adaptation; CL: Synthesize

8. 2. T-tube bile drainage is recorded separately on the output record. Adding the T-tube drainage to the urine output or wound drainage makes it difficult to accurately determine the amounts of bile, urine, or drainage. The client's total intake will be incorrect if drainage is subtracted from it.

CN: Reduction of risk potential; CL: Apply

9. 1. This client is exhibiting three of four signs of systemic inflammatory response syndrome (SIRS): temperature $>100.4^{\circ}\text{F}$ (38°C) (or $<96.8^{\circ}\text{F}$ [36°C]), heart rate >90 bpm, and respiratory rate >20 breaths/min. The fourth indicator is an abnormal white blood cell count ($>12,000$ [$12 \times 10^9/\text{L}$], <4000 [$4 \times 10^9/\text{L}$], or $>10\%$ [$0.1 \times 10^9/\text{L}$] bands). At least two of these variables are required to define SIRS.

CN: Physiological integrity; CL: Evaluate

10. 4. Lean meats, such as beef, lamb, veal, and well-trimmed lean ham and pork, are low in fat. Rice, pasta, and vegetables are low in fat when not served with butter, cream, or sauces. Fruits are low in fat. The amount of fat allowed in a client's diet after a cholecystectomy will depend on the client's ability to tolerate fat. Typically, the client does not require a special diet but is encouraged to avoid excessive fat intake. A cheese omelet and peanut butter have high fat content. Ham salad is high in fat from the fat in a mayonnaise-based salad dressing.

CN: Basic care and comfort; CL: Apply

11. 1. Hydromorphone should be considered for pain management. It should be administered intravenously for rapid action to address the severe pain the client is experiencing. Intramuscular injections are painful and slower acting. Since meperidine's toxic metabolite can cause seizures, it is no longer the treatment choice for pain. Diltiazem, a calcium channel blocker, is not indicated. Elevation of heart rate and blood pressure is likely due to pain and fever. Promethazine is used to treat nausea.

 CN: Pharmacological and parenteral therapies; CL: Synthesize

12. 1.4 mL.

The following formula is used to calculate the correct dosage:

$$\begin{aligned} 35 \text{ mg}/X \text{ mL} &= 25\text{mg} / 1 \text{ mL} \\ X &= 1.4 \text{ mL} \end{aligned}$$

 CN: Pharmacological and parenteral therapies; CL: Apply

13. 3. Immediately after surgery, the client will drink liquids. A light diet can be resumed the day after surgery. There is no need for the client to remain on nothing-by-mouth status after surgery because peristaltic bowel activity should not be affected. The client will probably not be able to tolerate a full meal comfortably the day after surgery. There is no need for the client to stay on a bland diet after a laparoscopic cholecystectomy. The client should, however, avoid excessive fats.

 CN: Physiological adaptation; CL: Synthesize

14. 3. After a laparoscopic cholecystectomy when there are sutures covered by a dressing, the client should not remove dressings from the puncture sites but should wait until visiting the surgeon. The client may shower 48 hours after surgery. A client can return to work within 1 week, but only if approved by the surgeon and no strenuous activity is involved. The client should report any fever, which could be an indication of a complication.

 CN: Reduction of risk potential; CL: Synthesize

15. 1,3,5. Following a laparoscopic cholecystectomy, the client can resume a normal diet as tolerated. The client may experience right shoulder

pain from the gas that was used to inflate the abdomen during surgery. The client can take a shower 48 hours after the surgery. The adhesive strips will fall off in about 10 days. The client can resume driving within 3 to 4 days following surgery as long as the client is not taking pain medication. There is no need for the client to maintain bed rest in the days following surgery. Light exercise such as walking can be resumed immediately.

 CN: Physiological adaptation; CL: Evaluate

16. 4. Portable suction units should be emptied and drained every shift or when full. It is normal for the unit to fill within the first hours after surgery; the nurse does not need to contact the surgeon. There should not be bleeding on the dressing if the drainage system is emptied when full. The drain should not be removed until prescribed by the **healthcare provider (HCP)** .

 CN: Management of care CL: Synthesize

The Client with Pancreatitis

17. 1. Alcoholism is a major cause of acute pancreatitis in the United States and Canada. Because some clients are reluctant to discuss alcohol use, staff may inquire about it in several ways. Generally, alcohol intake does not interfere with the tests used to diagnose pancreatitis. Recent ingestion of large amounts of alcohol, however, may cause an increased serum amylase level. Large amounts of ethyl and methyl alcohol may produce an elevated urinary amylase concentration. All clients are asked about alcohol and drug use on hospital admission, but this information is especially pertinent for clients with pancreatitis. **HCPs**  do need to seek facts, but this can be done while respecting the client's religious beliefs. Respecting religious beliefs is important in providing holistic client care.

 CN: Health promotion and maintenance; CL: Apply

18. 2. Grey Turner's sign is a bluish discoloration in the flank area caused by retroperitoneal bleeding. The vital signs are showing hemodynamic instability. IV access should be obtained to provide immediate volume replacement. The urine output will provide information on the fluid status. A nasogastric tube is indicated for clients with uncontrolled nausea and vomiting or gastric distension. Repositioning the client may be considered for

pain management once the client's vital signs are stable.

CN: Physiological adaptation; CL: Synthesize

19. 3. PRBCs are ordered to improve the low hemoglobin level; therefore, the nurse assesses for an increase in hemoglobin. The PRBCs do not increase BP; colloid solutions are needed to increase the circulating blood volume and raise the BP. The client has acute pain and requires the use of analgesia to minimize the pain. The platelet count is within normal limits and is not affected by the infusion of PRBCs.

CN: Physiological Adaptation; CL: Evaluate

20. 1. Furosemide can cause pancreatitis. Additionally, hypovolemia can develop with acute pancreatitis, and furosemide will further deplete fluid volume. Imipenem is indicated in the treatment of acute pancreatitis with necrosis and infection. Research no longer supports meperidine over other opiates. Morphine and hydromorphone are opiates of choice in acute pancreatitis to get pain under control. Famotidine is a histamine-2 receptor antagonist used to decrease acid secretion and prevent stress or peptic ulcers.

CN: Pharmacological and parenteral therapies; CL: Synthesize

21. 4. The client with acute pancreatitis is prone to complications associated with the respiratory system. Pneumonia, atelectasis, and pleural effusion are examples of respiratory complications that can develop as a result of pancreatic enzyme exudate. Pancreatitis does not cause heart failure, ulcer formation, or cirrhosis.

CN: Reduction of risk potential; CL: Analyze

22. 1,4,5. The client with acute pancreatitis usually experiences acute abdominal pain. Placing the client in a side-lying position relieves the tension on the abdominal area and promotes comfort. A semi-Fowler's position is also appropriate. The nurse should also monitor the client's respiratory status because clients with pancreatitis are prone to develop respiratory complications. Daily weights are obtained to monitor the client's nutritional and fluid volume status. While the client will likely need opioid analgesics to treat the pain, morphine sulfate is not appropriate as it stimulates spasm of the sphincter of Oddi, thus increasing the client's discomfort. During the

acute phase of the illness while the client is experiencing pain, the pancreas is rested by withholding food and drink. When the diet is reintroduced, it is a high-carbohydrate, low-fat, bland diet.

CN: Physiological adaptation; CL: Synthesize

23. 1. Hypocalcemia develops in severe cases of acute pancreatitis. The exact cause is unknown. Signs and symptoms of hypocalcemia include jerking and muscle twitching, numbness of fingers and lips, and irritability. Meperidine may cause tremors or seizures as an adverse effect, but not muscle twitching. Muscle twitching is not caused by a nutritional deficit, nor does it indicate that the client needs a muscle relaxant.

CN: Reduction of risk potential; CL: Analyze

24. 1. Propantheline is an anticholinergic, antispasmodic medication that decreases vagal stimulation and pancreatic secretions. It is contraindicated in paralytic ileus; therefore, the nurse should be concerned with the absent bowel sounds. Side effects are urinary retention, constipation, and tachycardia.

CN: Pharmacological and parenteral therapies; CL: Analyze

25. 1. Crash dieting or bingeing may cause an acute attack of pancreatitis and should be avoided. Carbohydrate intake should be increased because carbohydrates are less stimulating to the pancreas. There is no need to maintain a dietary pattern of six meals a day; the client can eat whenever desired. There is no need to place the client on a sodium-restricted diet because pancreatitis does not promote fluid retention.

CN: Physiological adaptation; CL: Synthesize

26. 2. In chronic pancreatitis, destruction of pancreatic tissue requires pancreatic enzyme replacement. Pancreatic enzymes are prescribed to facilitate the digestion of proteins and fats and should be taken in conjunction with every meal and snack. Specified hours or limited times for administration are ineffective because the enzymes must be taken in conjunction with food ingestion.

CN: Pharmacological and parenteral therapies; CL: Apply

27. 3. If the dosage and administration of pancreatic enzymes are adequate, the client's stool will be relatively normal. Any increase in odor or fat content would indicate the need for dosage adjustment. Stable body weight would be another indirect indicator. Fluid intake does not affect enzyme replacement therapy. If diabetes has developed, the client will need to monitor glucose levels. However, glucose and ketone levels are not affected by pancreatic enzyme therapy and would not indicate effectiveness of the therapy.

CN: Pharmacological and parenteral therapies; CL: Evaluate

28. 1. The fluid weight gain is of concern since the drug should be used with caution with impaired renal function. Dosage adjustment may be needed with renal insufficiency since the drug is excreted in the urine. Nausea, mild temperature elevation, and fatigue are symptoms that should be monitored, but are associated with hepatitis.

CN: Pharmacological and parenteral therapies; CL: Synthesize

The Client with Viral Hepatitis

29. 4. Acetaminophen is toxic to the liver and should be avoided in a client with liver dysfunction. Increased periods of rest allow for liver regeneration. A low-fat, high-carbohydrate diet and dry toast to relieve nausea are appropriate.

CN: Health promotion and maintenance; CL: Evaluate

30. 4. Hepatitis B is considered a sexually transmitted disease, and students should observe safe sex practices. Poor sanitary conditions in underdeveloped countries relate to spread of hepatitis A and E. Focusing on routes of transmission and avoidance of infection can prevent the spread of hepatitis; isolation in single rooms is not required. There is no vaccine for hepatitis D.

CN: Reduction of risk potential; CL: Synthesize

31. 2. Liver inflammation and obstruction block the normal flow of bile. Excess bilirubin turns the skin and sclerae yellow and the urine dark and frothy. Profound anorexia is also common. Tarry stools are indicative of

gastrointestinal bleeding and would not be expected in hepatitis. Light- or clay-colored stools may occur in hepatitis owing to bile duct obstruction. Shortness of breath would be unexpected.

CN: Physiological adaptation; CL: Analyze

32. 1. The main route of transmission for hepatitis A is the oral-fecal route, rarely parenteral. Good handwashing before eating or preparing food is essential to preventing spread of the disease. Percutaneous transmission is seen with hepatitis B, C, and D. Alpha-interferon is used for treatment of chronic hepatitis B and C.

CN: Safety and infection control; CL: Synthesize

33. 3. Clients with hepatitis C should receive genotype testing to determine the most effective treatment approach, and it must be done prior to the start of drug treatment with alpha-interferon. There are six types of hepatitis C genotypes, and clients have different responses to drugs depending on their genotype. For example, clients with genotype 2 or 3 are three times more likely to respond to treatment than those with genotype 1. The recommended course of duration of treatment also depends on genotype. Clients with genotype 2 or 3 usually have a 24-week course of treatment, whereas a 48-week course is recommended for clients with genotype 1. HCV has a high possibility of converting to chronic HCV and will not resolve in 2 to 4 months.

CN: Physiologic adaptation; CL: Apply

34. 2,4,5. Clients with chronic hepatitis C should abstain from alcohol as it can speed cirrhosis and end-stage liver disease. Clients should also check with their **HCPs**  before taking any nonprescription or prescription medications, or herbal supplements. It is also important that clients who are infected with HCV be tested for HIV, as clients who have both HIV and HCV have a more rapid progression of liver disease than do those who have HCV alone. Clients with HCV and nausea should be instructed to eat four to five times a day to help reduce anorexia and nausea. The client should obtain sufficient rest to manage the fatigue.

CN: Physiologic adaptation; CL: Synthesize

35. 4. During the convalescent or posticteric stage of hepatitis, fatigue and malaise are the most common problems. These symptoms usually disappear within 2 to 4 months. Fatigue and malaise are not evidence of a secondary infection. Hepatitis A is not treated by drug therapy. It is important that the client continue to balance activity with periods of rest.

CN: Reduction of risk potential; CL: Synthesize

36. 4. Although primarily bloodborne, unprotected sex with multiple partners and a history of sexually transmitted disease are risk factors for transmission of the hepatitis C virus. Other risk factors include blood transfusions, past treatment with chronic hemodialysis, being a child born to woman infected with hepatitis C virus, past/current illicit IV drug use, or needlestick injuries to healthcare workers. It is important for the nurse to be aware of the client's history in order to help determine the client's level of understanding of the disease, promote a healthy lifestyle, and discuss the role of viral transmission of the disease.

CN: Safety and infection control; CL: Synthesize

37. 1. Current therapy includes a combination of IV interferon and ribavirin that often includes unpleasant side effects and requires frequent monitoring. The recent approval of oral, directly acting antiviral agents (telaprevir, boceprevir, sofosbuvir, simeprevir) is expected to decrease monitoring rates and increase cure rates, though these drugs are currently very expensive. Though answers 3 and 4 may be true, it is not appropriate for the nurse to make judgments about a client's health insurance or lifestyle choices.

CN: Pharmacological and parenteral therapies; CL: Synthesize

38. 1. Treatment of hepatitis consists primarily of bed rest with bathroom privileges. Bed rest is maintained during the acute phase to reduce metabolic demands on the liver, thus increasing its blood supply and promoting liver cell regeneration. When activity is gradually resumed, the client should be taught to rest before becoming overly tired. Although adequate fluid intake is important, it is not necessary to force fluids to treat hepatitis. Antibiotics are not used to treat hepatitis. Electrolyte imbalances are not typical of hepatitis.

 CN: Basic care and comfort; CL: Synthesize

39. 1. The prothrombin time may be prolonged because of decreased absorption of vitamin K and decreased production of prothrombin by the liver. The client should be assessed carefully for bleeding tendencies. Blood glucose, serum potassium, and serum calcium levels are not affected by hepatitis.

 CN: Reduction of risk potential; CL: Analyze

40. 2. Low-fat, high-protein, high-carbohydrate diet is encouraged for a client with hepatitis to promote liver rejuvenation. Nutrition intake is important because clients may be anorexic and experience weight loss. Activity should be modified and adequate rest obtained to promote recovery. Social isolation should be avoided, and education on preventing transmission should be provided; the client does not need to sleep in a separate room.

 CN: Health promotion and maintenance; CL: Synthesize

41. 3. The hepatitis A virus is transmitted via the fecal-oral route. It spreads through contaminated hands, water, and food, especially shellfish growing in contaminated water. Certain animal handlers are at risk for hepatitis A, particularly those handling primates. Frequent handwashing is probably the single most important preventive action. Insects do not transmit hepatitis A. Family members do not need to stay away from the client with hepatitis. It is not necessary to disinfect food and clothing.

 CN: Safety and infection control; CL: Synthesize

42. 4. The most appropriate goal for this client with hepatitis is to increase activity gradually as tolerated. Periods of alternating rest and activity should be included in the plan of care. There is no evidence that the client is physically immobile, is unable to provide self-care, or needs to adapt to new energy levels.

 CN: Basic care and comfort; CL: Analyze

43. 3. Interferon alfa-2b most commonly causes flulike adverse effects, such as myalgia, arthralgia, headache, nausea, fever, and fatigue. Retinopathy is a potential adverse effect, but not a common one. Diarrhea may develop as

an adverse effect. Clients are advised to administer the drug at bedtime and get adequate rest. Medications may be prescribed to treat the symptoms. The drug may also cause hematologic changes; therefore, laboratory tests such as a complete blood count and differential should be conducted monthly during drug therapy. Blood glucose laboratory values should be monitored for the development of hyperglycemia.

CN: Pharmacological and parenteral therapies; CL: Analyze

44. 4. Hepatitis B is spread through exposure to blood or blood products and through high-risk sexual activity. Hepatitis B is considered to be a sexually transmitted disease. High-risk sexual activities include sex with multiple partners, unprotected sex with an infected individual, male homosexual activity, and sexual activity with IV drug users. College students are at high risk for development of hepatitis B and are encouraged to be immunized. Alcohol intake by itself does not predispose an individual to hepatitis B, but it can lead to high-risk behaviors such as unprotected sex. Good personal hygiene alone will not prevent the transmission of hepatitis B.

CN: Safety and infection control; CL: Create

45. 2. The client should be able to verbalize the importance of reporting any bleeding tendencies that could be the result of a prolonged prothrombin time. Ascites is not typically a clinical manifestation of hepatitis; it is associated with cirrhosis. Alcohol use should be eliminated for at least 1 year after the diagnosis of hepatitis to allow the liver time to fully recover. There is no need for a client to be restricted to the home because hepatitis is not spread through casual contact between individuals.

CN: Physiological adaptation; CL: Evaluate

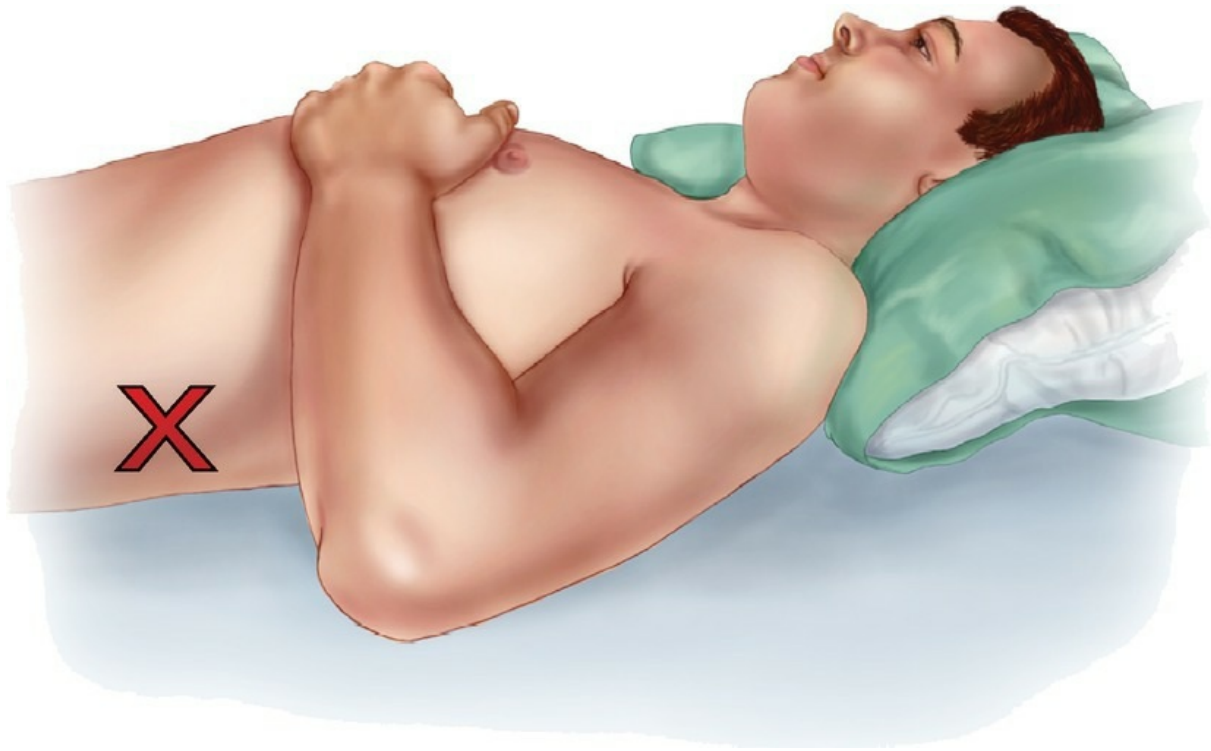

The Client with Cirrhosis

46. 1. Because the biopsy needle insertion site is close to the lung, there is a risk of lung puncture and pneumothorax; therefore, immediately after the procedure, the nurse should determine diminished or absent lung sounds in the right lung. Although fever indicates infection, a rise in temperature is not seen immediately. A CBC is warranted if the vital signs and client symptoms indicate potential hemorrhage. The needle insertion site is covered with a

pressure dressing; there is no need for a dressing requiring packing.

 CN: Safety and infection control; CL: Synthesize

47. The nurse places the client in supine position and percusses each flank for shifting dullness. If fluid is present, dullness is noted.

 CN: Physiological Adaptation; CL: Apply

48. 1. Clients with cirrhosis can develop hepatic encephalopathy caused by increased ammonia levels. Asterixis, a flapping tremor, is a characteristic symptom of increased ammonia levels. Bacterial action on increased protein in the bowel will increase ammonia levels and cause the encephalopathy to worsen. GI bleeding and protein consumed in the diet increase protein in the intestine and can elevate ammonia levels. Lactulose is given to reduce ammonia formation in the intestine and should not be held since neurological symptoms are worsening. Bilirubin is associated with jaundice.

 CN: Pharmacological and parenteral therapies; CL: Synthesize

49. 3. Hypokalemia is a precipitating factor in hepatic encephalopathy. A decrease in creatinine results from muscle atrophy; an increase in creatinine would indicate renal insufficiency. With liver dysfunction, increased

aldosterone levels are seen. A decrease in serum protein will decrease colloid osmotic pressure and promote edema.

CN: Physiological adaptation; CL: Synthesize

50. 4. Portal hypertension and hypoalbuminemia as a result of cirrhosis cause a fluid shift into the peritoneal space causing ascites. In a cardiac or kidney problem, not cirrhosis, sodium can promote edema formation and subsequent decreased urine output. Edema does not migrate upward toward the heart to enhance its circulation. Although diuretics promote the excretion of excess fluid, occasionally forgetting or omitting a dose will not yield the ascites found in cirrhosis of the liver.

CN: Physiological adaptation; CL: Synthesize

51. 1,2,3,4,5. Constipation leads to increased ammonia production. Lactulose is a hyperosmotic laxative that reduces blood ammonia by acidifying the colon contents, which retards diffusion of nonionic ammonia from the colon to the blood while promoting its migration from the blood to the colon. Hepatic encephalopathy is considered a toxic or metabolic condition that causes cerebral edema; it affects a person's coordination and pupil reaction to light and accommodation. Food and fluids high in carbohydrates should be given because the liver is not synthesizing and storing glucose. Because exercise produces ammonia as a by-product of metabolism, physical activity should be limited, not encouraged.

CN: Management of care; CL: Create

52. 3. Early clinical manifestations of cirrhosis are subtle and usually include gastrointestinal symptoms, such as anorexia, nausea, vomiting, and changes in bowel patterns. These changes are caused by the liver's altered ability to metabolize carbohydrates, proteins, and fats. Peripheral edema, ascites, and jaundice are later signs of liver failure and portal hypertension.

CN: Physiological adaptation; CL: Analyze

53. 2. Spironolactone is a potassium-sparing diuretic; therefore, clients should be monitored closely for hyperkalemia. Other common adverse effects include abdominal cramping, diarrhea, dizziness, headache, and rash. Constipation and dysuria are not common adverse effects of spironolactone.

An irregular pulse is not an adverse effect of spironolactone but could develop if serum potassium levels are not closely monitored.

CN: Pharmacological and parenteral therapies; CL: Analyze

54. 1. For clients who have cirrhosis without complications, a high-calorie, high-carbohydrate diet is preferred to provide an adequate supply of nutrients. In the early stages of cirrhosis, there is no need to restrict fat, protein, or sodium.

CN: Physiological adaptation; CL: Apply

55. 2,3,4. Baking soda baths can decrease pruritus. Keeping nails short and rubbing the area with knuckles can decrease breakdown when scratching. Calamine lotions help relieve itching. Alcohol will increase skin dryness. Sodium in the diet will increase edema and weaken skin integrity.

CN: Basic care and comfort; CL: Create

56. 2. General health promotion measures include maintaining good nutrition, avoiding infection, and abstaining from alcohol. It is not necessary to take multivitamins if the client is obtaining adequate nutrition. Rest and sleep are essential, but an impaired liver may not be able to detoxify sedatives and barbiturates. Such drugs must be used cautiously, if at all, by clients with cirrhosis. The client does not need to limit contact with others but should exercise caution to stay away from ill people.

CN: Health promotion and maintenance; CL: Synthesize

57. 4. Elevating the head of the bed will allow for increased lung expansion by decreasing the ascites pressing on the diaphragm. The client requires reassessment. A paracentesis is reserved for symptomatic clients with ascites with impaired respiration or abdominal pain not responding to other measures such as sodium restriction and diuretics. There is no indication for blood cultures. Heart sounds are assessed with the routine physical assessment.

CN: Physiological adaptation; CL: Synthesize

58. 1. Ascites can compromise the action of the diaphragm and increase the client's risk of respiratory problems. Ascites also greatly increases the

risk of skin breakdown. Frequent position changes are important, but the preferred position is Fowler's. Placing the client in Fowler's position helps facilitate the client's breathing by relieving pressure on the diaphragm. The other positions do not relieve pressure on the diaphragm.

CN: Reduction of risk potential; CL: Synthesize

59. 4. The client with esophageal varices is at even higher risk for bleeding with elevated PT/INR. The nurse and **HCP**  collaborate to prevent bleeding. The other laboratory findings are not as life threatening. A decreased serum albumin can cause fluid to move into the interstitial tissues. Increased ammonia levels are toxic to the brain. Calcium loss is more common to pancreatitis.

CN: Physiological Adaptation; CL: Synthesize

60. 1. Normal serum albumin is administered to reduce ascites. Hypoalbuminemia, a mechanism underlying ascites formation, results in decreased colloid osmotic pressure. Administering serum albumin increases the plasma colloid osmotic pressure, which causes fluid to flow from the tissue space into the plasma. Increased urine output is the best indication that the albumin is having the desired effect. An increased serum albumin level and increased ease of breathing may indirectly imply that the administration of albumin is effective in relieving the ascites. However, it is not as direct an indicator as increased urine output and reduced ascites. Anorexia is not affected by the administration of albumin.

CN: Pharmacological and parenteral therapies; CL: Evaluate

61. 1,3,2,4. The nurse should first assess the client to determine if the tube is obstructing the airway; assessment is done by assessing airflow. Once obstruction is established, the tube should be deflated and then quickly removed. A set of scissors should always be at the bedside to allow for emergency deflation of the balloon. Oxygen via face mask should then be applied once the tube is removed.

CN: Safety and infection control; CL: Synthesize

62. 3. The goal of abstinence from alcohol in clients with alcohol-induced cirrhosis is to improve the liver function; most clients have improved liver

function when they abstain from alcohol. Clients with cirrhosis do not necessarily have delirium tremens. Abstaining from alcohol may allow the client to improve nutritional status, but additional dietary counseling may be needed to achieve that goal. Clients with cirrhosis may have weight gain from ascites, but this is managed with diuretics.

 CN: Pharmacological and parenteral therapies; CL: Evaluate

63. 1. The client should be monitored closely for changes in mental status. Ammonia has a toxic effect on central nervous system tissue and produces an altered level of consciousness, marked by drowsiness and irritability. If this process is unchecked, the client may lapse into coma. Increasing ammonia levels are not detected by changes in blood pressure, urine output, or respirations.

 CN: Physiological adaptation; CL: Analyze

64. 3. Lactulose increases intestinal motility, thereby trapping and expelling ammonia in the feces. An increase in the number of bowel movements is expected as an adverse effect. Lactulose does not affect urine output. Any improvements in mental status would be the result of increased ammonia elimination, not an adverse effect of the drug. Nausea and vomiting are not common adverse effects of lactulose.

 CN: Pharmacological and parenteral therapies; CL: Apply

65. 60 mL

$$30 \text{ mL} = 1 \text{ oz}$$

The following formula is used to calculate the correct dosage:

$$30 \text{ mL}/1 \text{ oz} = X \text{ mL}/2 \text{ oz}$$

$$X = 60 \text{ mL.}$$

 CN: Pharmacological and parenteral therapies; CL: Apply

66. 2. The taste of lactulose is a problem for some clients. Mixing it with

fruit juice, water, or milk can make it more palatable. Lactulose should not be given with antacids, which may inhibit its action. Lactulose should not be taken with a laxative because increased stooling is an adverse effect of the drug and would be potentiated by using a laxative. Lactulose comes in the form of syrup for oral or rectal administration.

CN: Pharmacological and parenteral therapies; CL: Evaluate

67. 3. Clients with cirrhosis should be instructed to avoid constipation and straining at stool to prevent hemorrhage. The client with cirrhosis has bleeding tendencies because of the liver's inability to produce clotting factors. A low-protein and high-carbohydrate diet is recommended. Clients with cirrhosis should not take acetaminophen, which is potentially hepatotoxic. Aspirin also should be avoided if esophageal varices are present. Cirrhosis is a chronic disease.

CN: Reduction of risk potential; CL: Evaluate

68. 1. Immediately before a paracentesis, the client should empty the bladder to prevent perforation. The client will be placed in a high Fowler's position or seated on the side of the bed for the procedure. IV sedatives are not usually administered. The client does not need to be NPO.

CN: Reduction of risk potential; CL: Synthesize

69. 3. Edematous tissue is easily traumatized and must receive meticulous care. An alternating air pressure mattress will help decrease pressure on the edematous tissue. ROM exercises are important to maintain joint function, but they do not necessarily prevent skin breakdown. When abdominal skin is stretched taut due to ascites, it must be cleaned very carefully. The abdomen should not be massaged. Elevation of the lower extremities promotes venous return and decreases swelling.

CN: Reduction of risk potential; CL: Synthesize

Managing Care, Quality, and Safety of Clients with Biliary Tract Disorders

70. 4. Contact precautions are recommended for clients with hepatitis A. This includes wearing gloves for direct care. A gown is not required unless

substantial contact with the client is anticipated. It is not necessary to wear a mask. The client does not need a private room unless incontinent of stool.

CN: Safety and infection control; CL: Create

71. 4. A change in a client's baseline vital signs should be brought to the HCP's  attention immediately. In this case, the client's heart rate has increased, and the rhythm appears to have changed; the HCP may prescribe an ECG to determine if treatment is necessary. The nurse should also have a complete set of current vital signs as well as a physical assessment before providing the HCP information using the SBAR format. The nutritional as well as psychological needs of a client must be addressed but are not first priority. A rash that develops after a new antibiotic is started must be brought to the HCP attention; however, this client is stable and is not the first priority. The nurse is responsible to facilitate discussion between the client, the client's family, and the HCP, but only after all of the immediate physical and psychological needs of all clients have been met.

CN: Reduction of risk potential; CL: Synthesize

72. 1,3,2,4. The nurse should first assess the client with cirrhosis to ensure the client's safety and assess the client for the onset of hepatic encephalopathy. The nurse should then assess the client with acute pancreatitis who is requesting pain medication and administer the needed medication. The nurse should next assess the client who underwent a cholecystectomy and is 1 day postoperative to make sure that the T tube is draining and that the client is performing postoperative breathing exercises. This client's safety is not at risk, and the client is not reporting having pain. The nurse can speak last with the client with hepatitis B who has questions about discharge instructions because this client's issues are not urgent.

CN: Management of care; CL: Synthesize

73. 2. Hepatitis C is usually transmitted through blood exposure or needlesticks. A hepatitis C vaccine is currently under development, but it is not available for use. The first line of defense against hepatitis B is the hepatitis B vaccine. Hepatitis C is not transmitted through feces or urine. Wearing a gown and mask will not prevent transmission of the hepatitis C virus if the caregiver comes in contact with infected blood or needles.

 CN: Safety and infection control; CL: Apply

74. 1,3,4,2. Silencing the alarm will eliminate a stress to the client and allow the nurse to focus on the task at hand. The nurse should then assess the access site to note if the needle is inserted in the vein or if there is tissue trauma, infiltration, or inflammation. Next, the nurse should check for kinks in the tubing. Finally, the nurse can plug the pump into the wall to allow the battery to become recharged.

 CN: Pharmacological and parenteral therapies; CL: Synthesize

TEST

8

The Client with Endocrine Health Problems

- The Client with Disorders of the Thyroid
- The Client with Diabetes Mellitus
- The Client with Pituitary Adenoma
- The Client with Addison's Disease
- The Client with Cushing's Disease
- Managing Care, Quality, and Safety of Clients with Endocrine Health Problems
- Answers, Rationales, and Test-Taking Strategies

The Client with Disorders of the Thyroid

1. The nurse is completing a health assessment of a 42-year-old female with suspected Graves' disease. The nurse should assess this client for:

- ☐ **1.** anorexia.
- ☐ **2.** tachycardia.
- ☐ **3.** weight gain.
- ☐ **4.** cold skin.

2. When conducting a health history with a female client with thyrotoxicosis, the nurse should ask about which changes in the menstrual cycle?

- ☐ **1.** dysmenorrhea
- ☐ **2.** metrorrhagia
- ☐ **3.** oligomenorrhea
- ☐ **4.** menorrhagia

3. A 34-year-old female is diagnosed with hypothyroidism. What should

the nurse assess the client for? Select all that apply.

- ☐ 1. rapid pulse
- ☐ 2. decreased energy and fatigue
- ☐ 3. weight gain of 10 lb (4.5 kg)
- ☐ 4. fine, thin hair with hair loss
- ☐ 5. constipation
- ☐ 6. menorrhagia

4. Propylthiouracil (PTU) is prescribed for a client with Graves' disease. The nurse should teach the client to immediately report:

- ☐ 1. sore throat.
- ☐ 2. painful, excessive menstruation.
- ☐ 3. constipation.
- ☐ 4. increased urine output.

5. A client with thyrotoxicosis says to the nurse, "I am so irritable. I am having problems at work because I lose my temper very easily." Which response by the nurse would give the client the **most** accurate explanation of this behavior?

- ☐ 1. "Your behavior is caused by temporary confusion brought on by your illness."
- ☐ 2. "Your behavior is caused by the excess thyroid hormone in your system."
- ☐ 3. "Your behavior is caused by your worrying about the seriousness of your illness."
- ☐ 4. "Your behavior is caused by the stress of trying to manage a career and cope with illness."

6. The nurse is evaluating a client with hyperthyroidism who is taking propylthiouracil (PTU) 100 mg/day in three divided doses for maintenance therapy. Which statement from the client indicates the drug is effective?

- ☐ 1. "I have excess energy throughout the day."
- ☐ 2. "I am able to sleep and rest at night."
- ☐ 3. "I have lost weight since taking this medication."
- ☐ 4. "I do perspire throughout the entire day."

7. A client with hyperthyroidism is hospitalized to have a thyroidectomy. The healthcare provider (HCP) has prescribed propranolol. In reviewing the client's history, the nurse notes that the client has asthma. The nurse should **next:**

- ☐ **1.** take the client's pulse and withhold the propranolol if the pulse is <100 beats per minute.
- ☐ **2.** count the client's respirations and withhold the propranolol if the respirations are <20 breaths per minute.
- ☐ **3.** contact the HCP and discuss the prescription for propranolol because of the client's history of having asthma.
- ☐ **4.** instruct the client to make position changes slowly.

8. The nurse should teach the client with Graves' disease to prevent corneal irritation from mild exophthalmos by:

- ☐ **1.** massaging the eyes at regular intervals.
- ☐ **2.** instilling an ophthalmic anesthetic as prescribed.
- ☐ **3.** wearing dark-colored glasses.
- ☐ **4.** covering both eyes with moistened gauze pads.

9. After treatment with radioactive iodine (RAI, ^{131}I), the nurse should teach the client to:

- ☐ **1.** monitor for signs and symptoms of hyperthyroidism.
- ☐ **2.** rest for 1 week to prevent complications of the medication.
- ☐ **3.** take thyroxine replacement for the remainder of the client's life.
- ☐ **4.** assess for hypertension and tachycardia resulting from altered thyroid activity.

10. A client with a large goiter is scheduled for a subtotal thyroidectomy to treat thyrotoxicosis. Saturated solution of potassium iodide (SSKI) is prescribed preoperatively for the client. The expected outcome of using this drug is that it helps:

- ☐ **1.** slow progression of exophthalmos.
- ☐ **2.** reduce the vascularity of the thyroid gland.
- ☐ **3.** decrease the body's ability to store thyroxine.
- ☐ **4.** increase the body's ability to excrete thyroxine.

11. The nurse is administering a saturated solution of potassium iodide (SSKI). The nurse should:

- ☐ 1. pour the solution over ice chips.
- ☐ 2. mix the solution with an antacid.
- ☐ 3. dilute the solution with water, milk, or fruit juice and have the client drink it with a straw.
- ☐ 4. disguise the solution in a pureed fruit or vegetable.

12. Following a subtotal thyroidectomy, the nurse asks the client to speak immediately upon regaining consciousness. The nurse does this to monitor for signs of:

- ☐ 1. internal hemorrhage.
- ☐ 2. decreasing level of consciousness.
- ☐ 3. laryngeal nerve damage.
- ☐ 4. upper airway obstruction.

13. A client who has undergone a subtotal thyroidectomy is subject to complications in the first 48 hours after surgery. The nurse should obtain and keep at the bedside equipment to:

- ☐ 1. begin total parenteral nutrition.
- ☐ 2. initiate defibrillation.
- ☐ 3. administer tube feedings.
- ☐ 4. perform a tracheotomy.

14. One day following a subtotal thyroidectomy, a client begins to have tingling in the fingers and toes. The nurse should **first**:

- ☐ 1. encourage the client to flex and extend the fingers and toes.
- ☐ 2. notify the healthcare provider (HCP).
- ☐ 3. assess the client for thrombophlebitis.
- ☐ 4. ask the client to speak.

15. Which medication should be available to provide emergency treatment if a client develops tetany after a subtotal thyroidectomy?

- ☐ 1. sodium phosphate
- ☐ 2. calcium gluconate

- ☐ 3. echothiophate iodide
- ☐ 4. sodium bicarbonate

16. A 60-year-old female is diagnosed with hypothyroidism. The nurse should assess the client for:

- ☐ 1. tachycardia.
- ☐ 2. weight gain.
- ☐ 3. diarrhea.
- ☐ 4. nausea.

17. The nurse should assess a client with hypothyroidism for:

- ☐ 1. corneal abrasion due to inability to close the eyelids.
- ☐ 2. weight loss due to hypermetabolism.
- ☐ 3. fluid loss due to diarrhea.
- ☐ 4. decreased activity due to fatigue.

18. When discussing recent onset of feelings of sadness and depression in a client with hypothyroidism who has just started to take thyroid hormone replacement, the nurse should inform the client that these feelings are:

- ☐ 1. the effects of thyroid hormone replacement therapy and will diminish over time.
- ☐ 2. related to thyroid hormone replacement therapy and will not diminish over time.
- ☐ 3. a normal part of having a chronic illness.
- ☐ 4. most likely related to low thyroid hormone levels and will improve with treatment.

19. The nurse is instructing the client with hypothyroidism who takes levothyroxine 100 mcg, digoxin, and simvastatin. Teaching regarding the use of these medications is effective if the client will take:

- ☐ 1. the levothyroxine with breakfast and the other medications after breakfast.
- ☐ 2. the levothyroxine before breakfast and the other medications 4 hours later.
- ☐ 3. all medications together 1 hour after eating breakfast.
- ☐ 4. all medications before going to bed.

The Client with Diabetes Mellitus

20. The nurse is coaching a diabetic client using an empowerment approach. The nurse should initiate teaching by asking:

- ☐ 1. “How much does your family need to be involved in learning about your condition?”
- ☐ 2. “What is required for your family to manage your symptoms?”
- ☐ 3. “What activities are most important for you to be able to maintain control of your diabetes?”
- ☐ 4. “What do you know about your medications and condition?”

21. The nurse is obtaining a health history from a client with diabetes mellitus who has been taking insulin for 20 years. Currently, the client reports having periods of hypoglycemia followed by periods of hyperglycemia. The nurse should specifically ask if the client is:

- ☐ 1. eating snacks between meals.
- ☐ 2. initiating the use of the insulin pump.
- ☐ 3. injecting insulin at a site of lipodystrophy.
- ☐ 4. adjusting insulin according to blood glucose levels.

22. A nurse is participating in a diabetes screening program. Who are at risk for developing type 2 diabetes? Select all that apply.

- ☐ 1. a 32-year-old female who gave birth to a 9½-lb (4,300-g) infant.
- ☐ 2. a 44-year-old Native American (First Nations) who has a body mass index (BMI) of 32.
- ☐ 3. an 18-year-old immigrant from Mexico who jogs four times a week.
